INTRODUCTION

TO THE ARTICLES ON INORGANIC CHEMISTRY.

It has been thought advisable to include in an ADDENDA brief accounts of the chief work done in descriptive inorganic chemistry since the publication of Vols. I., II., and III., and the printing off the final proofs of Vol. IV.

Nothing bearing on organic chemistry has been included in the ADDENDA, as to give an account of what has been done in this department since the various volumes were published would occupy many hundred pages.

Dates are attached to the references made to original memoirs in the ADDENDA; and references are frequently made to abstracts of the memoirs in the *Journal of the Chemical Society.*

M. M. PATTISON MUIR.

INTRODUCTION

TO THE ARTICLES RELATING TO ORGANIC CHEMISTRY.

THE names used to denote ring formulæ are given below for convenience of reference.

Since the publication of the last volume I have been assisted in the work of reading and making abstracts of original memoirs by Drs. T. Cooksey, T. A. Lawson, Samuel Rideal, Messrs. J. Wilkie, G. N. Huntly, and J. T. Norman. I have also been assisted by Mr. Arthur G. Green and Mr. Cecil W. Cunnington in the work of revising the proof-sheets. I have great pleasure in thanking these gentlemen for the energetic and efficient manner in which they have carried out their share of the work.

H. FORSTER MORLEY.

Nomenclature of Ring Formulæ.

Hydrocarbons.

 $CH_2<\begin{matrix}CH_2\\CH_2\end{matrix}$	*Trimethylene.*
 $CH_2<\begin{matrix}CH_2\\CH_2\end{matrix}>CH_2$	*Tetramethylene.*
 $CH_2<\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}$	*Pentamethylene.*
 $CH<\begin{matrix}CH\\CH\end{matrix}>CH$	*Tetramethenyl.*
 $CH_2<\begin{matrix}CH:CH\\CH:CH\end{matrix}$	*Pentamethenyl hydride.*
 $C_6H_4<\begin{matrix}CH_2\\CH\end{matrix}>CH$	*Indonaphthene.*

Nitrogen compounds.

 $NH<\begin{matrix}CH:CH\\CH:CH\end{matrix}$	*Pyrrole.*
 $NH<\begin{matrix}N=CH\\CH:CH\end{matrix}$	*Pyrazole.*
 $NH<\begin{matrix}CH:N\\CH:CH\end{matrix}$	*Glyoxaline.*
 $N\ll\begin{matrix}CH:N\\CH.CH_2\end{matrix}$	*Metapyrazole.*
 $NH<\begin{matrix}CH:N\\CH:N\end{matrix}$ or $N\ll\begin{matrix}CH.NH\\CH:N\end{matrix}$	*Triazole.*
 $NH<\begin{matrix}N:CH\\N:CH\end{matrix}$	*Osotriazole.*
 $NH<\begin{matrix}N=N\\CH:N\end{matrix}$	*Tetrazole.*
 $NH<\begin{matrix}N=CH\\CH:N\end{matrix}$	*Pyrrodiazole.*
 $C_6H_4<\begin{matrix}CH\\NH\end{matrix}>CH$	*Indole.*
 $C_6H_4<\begin{matrix}CH\\N\end{matrix}>NH$	*Indazine.*
 $C_6H_4<\begin{matrix}CH\\NH\end{matrix}>N$	*Pseudo-indazine.*
 $C_6H_4<\begin{matrix}CH\\N\end{matrix}>C_6H_4$	*Acridine.*
 $C_6H_4<\begin{matrix}N\\N\end{matrix}>C_6H_4$	*Phenazine.*
 $N\ll\begin{matrix}CH:CH\\CH.CH\end{matrix}\gg CH$	*Pyridine.*
 $N\ll\begin{matrix}N=CH\\CH.CH\end{matrix}\gg CH$	*Pyridazine.*
 $N\ll\begin{matrix}CH:CH\\CH.CH\end{matrix}\gg N$	*Pyrazine.*
 $N\ll\begin{matrix}CH:N\\CH.CH\end{matrix}\gg CH$	*Pyrimidine.*
 $N\ll\begin{matrix}CH.\ N\\CH:\ N\end{matrix}\gg CH$	*Triazoline.*
 $N\ll\begin{matrix}N\ .\ N\\N\ :CH\end{matrix}\gg CH$	*Osotetrazole.*
 $C_6H_4<\begin{matrix}CH:CH\\N=CH\end{matrix}$	*Quinoline.*
 $C_6H_4<\begin{matrix}CH:CH\\CH:N\end{matrix}$	*Isoquinoline.*
 $C_6H_4<\begin{matrix}N\ :CH\\N\ :CH\end{matrix}$	*Quinoxaline.*
 $C_6H_4<\begin{matrix}CH:N\\N=CH\end{matrix}$	*Quinazoline.*
 $C_6H_4<\begin{matrix}CH:CH\\N=N\end{matrix}$	*Cinnoline.*
 $C_6H_4<\begin{matrix}CH:N\\N\ :N\end{matrix}$	*Phentriazine.*
 $C_6H_4<\begin{matrix}\overline{\qquad\qquad C:N}\\C(NH).CH:C.NPh\end{matrix}>C_6H_4$	*Rosinduline.*
 $C_6H_4<\begin{matrix}\overline{\qquad\qquad C:N.}\\C(NH).CH:C.NPh\end{matrix}>C_{10}H_6$	{ *Naphthoros induline.*

Oxygen compounds.

$O<\begin{matrix}CH:CH\\CH:CH\end{matrix}$ *Furfurane.*

$O<\begin{matrix}CH:N\\CH:CH\end{matrix}$ *Oxazole.*

$O<\begin{matrix}N-CH\\CH:CH\end{matrix}$ *Iso-oxazole* or *Isoxazole.*

$O<\begin{matrix}CH:N\\CH:N\end{matrix}$ *Biazole.*

$C_6H_4<\begin{matrix}CH\\O\end{matrix}>CH$ *Coumarone.*

$C_6H_4<\begin{matrix}CH\\O\end{matrix}>N$ *Indoxazine.*

$CO<\begin{matrix}NH\\NH\end{matrix}$ *Carbizine.*

$O<\begin{matrix}CH:CH\\CH:CH\end{matrix}>CH_2$ *Furidane.*

$O<\begin{matrix}CH:CH\\CH:CH\end{matrix}>NH$ *Pyroxazine.*

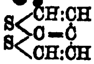
$O<\begin{matrix}CH.NH\\CH.CH\end{matrix}>CH$ *Pyroximidine.*

$C_6H_4<\begin{matrix}O-CH\\NH.CH\end{matrix}$ *Quinoxazine.*

$C_6H_4<\begin{matrix}O\\NH\end{matrix}>C_6H_4$ *Phenoxazine* or *Phenazoxine.*

Sulphur compounds.

$S<\begin{matrix}CH:CH\\CH:CH\end{matrix}$ *Thiophene.*



$\begin{matrix}S<\\S<\end{matrix}\begin{matrix}CH:CH\\C=C\\CH:CH\end{matrix}$ *Thiophthene.*

$C_6H_4<\begin{matrix}N\\S\end{matrix}>CH$ *Methenyl-amido-phenyl-mercaptan.*

$S<\begin{matrix}CH:N\\CH:CH\end{matrix}$ *Thiazole.*

$S<\begin{matrix}CH:N\\CH:N\end{matrix}$ *Diazthiole. Thiobiazole.*

$S<\begin{matrix}CH-N\\CH\ .\ CH_2\end{matrix}>CH$ *Penthiazole.*

$C_6H_4<\begin{matrix}N\\N\end{matrix}>S$ *Piazthiole.*

$C_6H_4<\begin{matrix}NH\\S\end{matrix}>C_6H_4$ *Imido-di-phenyl-sulphide.*

II. Terms and Quantities, &c., frequently used.

Aq.	Water; e.g. NaOHAq means an aqueous solution of caustic soda.
aq.	18 parts by weight of water.
A' A'' A'''	Residues of mono-, di-, and tri-basic acids. Thus, in describing the salts of a monobasic acid NaA', CaA'_2, AlA'_3 may be written, HA' standing for the acid. For a dibasic acid we should write Na_2A'', CaA'', $Al_2A''_3$ &c.
B' B'' etc.	Stand for bases of the ammonia type, in describing their salts. Thus the hydrochloride would be $B'HCl$ or $B''2HCl$, according as the base is monacid or diacid, &c.
conc.	Concentrated.
dil.	Dilute.
g.	gram.
mgm.	milligram.
mm.	millimetre.
mol.	molecule.
oil.	liquid, nearly, or quite, insoluble in water.
pp.	precipitate.
to ppt.	to precipitate.
ppg.	precipitating.
ppd.	precipitated.

ABBREVIATIONS.

[illegible]	soluble in.
insol.	insoluble in.
v. e. sol.	very easily
v. sol.	very
m. sol.	moderately } soluble in.
sl. sol.	slightly
v. sl. sol.	very slightly
v.	see.
cf.	compare.
c.	about.
[°]	a melting-point.
(°)	a boiling-point.
H.	Hardness (of minerals).
At. w.	Atomic weight.
Mol. w. or M. w.	Molecular weight.
D.	Density.
cor.	corrected.
uncor.	uncorrected.
i.V.	in vapour.
V.D.	vapour-density, *i.e.* density of a gas compared with hydrogen or air
S.G.	Specific gravity compared with water.
S.G. $\frac{10}{0}$	,, ,, at 10° compared with water at 0°.
S.G. $\frac{15}{4}$	,, ,, ,, 15° ,, ,, ,, ,, 4°.
S.G. ^{12}	,, ,, ,, 12°; compared with water of which the temperature is not given.
S.H.	Specific heat.
S.H. v.	,, ,, of a gas at constant volume.
S.H. p.	,, ,, ,, ,, ,, pressure.
H.C.	Quantity of heat, in gram-units, produced during the complete combustion of the mass of a solid or liquid body represented by its formula, taken in grams.
H.C. v.	Heat of combustion in gram-units of a gram-molecule of an element or compound, when gaseous, under constant volume.
H.C. p.	The same, under constant pressure.
H.F.	Quantity of heat, in gram-units, produced during the formation of the mass of a solid or liquid body represented by its formula, taken in grams, from the masses of its constituent elements expressed by their formulæ, taken in grams.
H.F. v.	Heat of formation of a gram-molecule of a gaseous compound from the gram-molecules of its elements under constant volume.
H.F. p.	The same, under constant pressure.
H.V.	Heat of vaporisation of a liquid, *i.e.* gram-units of heat required to change a gram-molecule of the liquid compound at B. P. into gas at same temperature and pressure.
T.C.	Thermal conductivity (unit to be stated).
S.V.	Specific volume; or the molecular weight of a gaseous compound divided by the S.G. of the liquid compound at its boiling-point compared with water at 4°.
S.V.S.	Specific volume of a solid; or the mass of the solid expressed by its formula, taken in grams, divided by its S.G.
E.C.	Electrical conductivity (the unit is stated in each case).
C.E. (10° to 20°)	Coefficient of expansion (between 10° and 20°).
S.	Solubility in water { of a gas = volume dissolved by 1 volume of water. of a liquid or solid = number of grms. dissolved by 100 grms. of water. In both cases the temperature is stated.
S. (alcohol)	,, ,, alcohol
μ_β	Index of refraction for hydrogen line β.
μ_D, &c.	,, ,, ,, sodium ,, ,, D, &c.
$R_D \frac{15}{0}$	Molecular refraction for sodium light, i.e. index of refraction for line D minus one, multiplied by molecular weight, and divided by S.G. at 15° compared with water at 0°.
R_D	The same; S.G. being determined at 15°–20° and referred to water at 4°.
R_∞	The same for line of infinite wave-length, index being determined by Cauchy's formula (Brühl's R_A).
$[\alpha]_D$	Specific rotation for sodium light.
$[\alpha]_j$	,, ,, ,, neutral tint. $[\alpha] = \frac{100}{p} \times \frac{a}{d}$. a = observed rotation for 100 mm. of liquid. d = S.G. of liquid. p = no. of grammes of active substance in 100 grammes of liquid.

M. M.	Molecular magnetic rotatory power $= \frac{m \times \alpha}{d \times \alpha' \times m'}$, where m = molecular weight of the body of S.G. = d, α = angle of rotation under magnetic influence, α' = angle of rotation of water under same influence, and m' = molecular weight of water (18).	
Ac	Acetyl C_2H_3O.	
Bz	Benzoyl C_7H_5O.	
Cy	Cyanogen CN.	
Et	Ethyl C_2H_5.	in formulæ.
Me	Methyl CH_3.	
Ph	Phenyl C_6H_5.	
Pr	Normal Propyl $CH_2.CH_2.CH_3$.	
Pr	Isopropyl $CH(CH_3)_2$.	
R, R' &c.	Alcohol radicles or alkyls.	
prim	primary.	
sec	secondary.	
tert	tertiary.	
n	normal.	
m, *o*, *p*	meta—ortho—para.	
c	consecutive.	
i	irregular.	
s	symmetrical.	
u	unsymmetrical.	
ψ	pseudo.	
ν	attached to nitrogen.	
α β γ	Employed to denote that the substituent is attached to a carbon atom which is next, next but one, or next but two, respectively, to the terminal carbon atom. The end to be reckoned from is determined by the nature of the compound. Thus $CH_3.CHBr.CO_2H$ is α-bromo-propionic acid.	
ω	denotes that the element or radicle which follows it is attached to a terminal carbon atom.	
α, β, γ, &c.	indicate position in an open chain, only.	
1, 2, 3, &c.	indicate position in a ring only.	
(α), (β), &c.	Used when α, β, &c. are employed in a sense different from the above, *e.g.* (α)-di-bromo-camphor.	
	Baeyer's Nomenclature:	
(*B.*)	benzene ring.	
(*Py.*)	pyridine ring. Thus (*B.* 1:3) dichloroquinoline, means a meta-dichloroquinoline in which the chlorine atoms are both in the benzene ring. While (*Py.* 1:3) dichloroquinoline, means a similar body, only the chlorine atoms are in the pyridine ring. The numbers are counted from two carbon atoms which are in different rings, but both united to the same carbon atom.	
(*A.*)	denotes the central ring in the molecule of anthracene, acridines, and azines.	
eso-	means that the element or radicle it precedes is in a closed ring.	
exo-	„ „ „ „ „ not in a benzene ring.	
allo-	denotes isomerism that is not indicated by ordinary formulæ; thus maleic acid may be called *allo*-fumaric acid.	
thio-	denotes displacement of oxygen by sulphur.	
sulpho-	„ the group SO_3H, except in the word sulphocyanide.	
sulphydro-	„ the group SH.	
	Tribromonitrobenzene sulphonic acid [1:2:3:4:5] means that the three bromines occupy positions 1, 2, and 3; the nitro- group the position 4, and the sulpho- group the position 5.	

* Denotes that the formula to which it is affixed has not been determined by analysis. But it by no means follows that formulæ without this mark are those of analysed compounds.

All temperatures are given in degrees Centigrade unless when specially stated otherwise.

Wave-lengths are given in 10^{-7} mm.

Formulæ, when used instead of names of substances, have a qualitative meaning only.

Thomsen's notation is used in thermochemical data.

DICTIONARY OF CHEMISTRY

PHENYL-AZOXAZOLE $\begin{matrix}CH:N\\ CPh:N\end{matrix}\!\!>O$. [30°]. Formed by the action of CO_2 on an alkaline solution of the oxim of phenyl-glyoxal (Russanoff, *B.* 24, 3503). Needles, insol. water.

PHENYL-BENZAMIDINE $C_{13}H_{12}N_2$ *i.e.* $C_6H_5C(NH).NHPh$ or $C_6H_5.C(NPh).NH_2$ [112°]. Formed from benzonitrile and aniline hydrochloride at 230° (Bernthsen, *A.* 184, 348; 192, 33). Formed also from benzimido-ether and aniline, and from CPhCl:NPh and NH_3 (Kobbert, *A.* 265, 138). Nodules (from alcohol), sl. sol. water. Forms a crystalline nitrate.

Reactions.—1. Split up by heat into aniline and benzonitrile.—2. Dry H_2S at 130° forms $C_6H_5.CS.NHPh$ and some thio-benzamide.—3. CS_2 at 100° forms thio-benzanilide and phenyl-benzamidine sulphocyanide.—4. Reduced by sodium-amalgam to $C_6H_5.CH(NH_2).NHPh$.—5. *Nitrous* acid forms benzanilide (Mieran, *A.* 265, 141).

The derivatives $C_6H_5C(N.SO_2Ph).NHPh$ [139°] and $C_6H_4(SO_2N:C(NHPh).C_6H_5)_2$ [196°] have been prepared (Wallach, *A.* 214, 214; Jackson, *Am.* 9, 346).

s-**Di-phenyl-benzamidine** $C_{19}H_{16}N_2$ *i.e.* $C_6H_5.C(NPh).NHPh$. [144°].

Formation.—1. From benzanilide by treatment with PCl_5 and aniline (Gerhardt, *A.* 108, 219; Hofmann, *Z.* 1866, 161; Wallach, *A.* 184, 83).—2. From $Ph.CCl_3$ and aniline with or without $ZnCl_2$ (Limpricht, *A.* 135, 82; Döbner, *B.* 15, 233).—3. A product of the action of aniline hydrochloride at 250° on benzonitrile, thiobenzamide, or phenyl-benzamidine (Bernthsen, *A.* 184, 352).—4. By heating benzanilide with phenyl cyanate at 190° (Kühn, *B.* 18, 1476).—5. By heating the hydrochloride of benzimido-ether in alcohol with aniline for a long time (Kobbert, *A.* 265, 155).

Properties.—Needles (from alcohol), m. sol. benzene. Its alcoholic solution is neutral to litmus. Not affected by nitrous acid. Split up into aniline and benzanilide when boiled for a long time with alcohol.

Reactions.—1. Dry H_2S at 160° forms thio-benzanilide.—2. CS_2 at 140° forms PhCS.NHPh and NPhCS (Bernthsen, *A.* 192, 34).—3. Conc. HClAq at 1[illegible]° yields aniline and benzoic acid.

Salts.—B'HCl: v. sl. sol. water.—$B'_2H_2PtCl_6$.—$B'C_6H_3N_3O_7$: yellow needles.

u-**Di-phenyl-benzamidine** $C_6H_5.C(NH).NPh_2$. [112°]. Formed by heating diphenylamine hydrochloride with benzonitrile at [illegible] for 5 days (Bernthsen, *A.* 192, 5). Trimetric tablets, v. sol. alcohol and benzene.

Its alcoholic solution turns litmus blue. Conc. H_2SO_4 gives a violet-blue colour on warming.

Reactions.—1. Dilute HClAq at 150° forms NPh_2Bz.—2. The free base and its hydrochloride yield benzonitrile and diphenylamine on heating.—3. Nitrous acid forms NPh_2Bz (Klobbert, *A.* 265, 157).—4. H_2S at 130° forms $Ph.CS.NH_2$, diphenylamine, $PhCS.NPh_2$, and NH_3.—5. CS_2 at 140° forms $PhCS.NPh_2$ and HNCS.

Salts.—B'HCl. [c. 223°]. Monoclinic crystals, $a:b:c = {\cdot}529:1:{\cdot}507$; $\beta = 85°52'$. V. sol. water, sol. alcohol, insol. ether.—$B'_2H_2PtCl_6$.—B'HNCS. [203°]. Yellow prisms.

PHENYL-BENZAMIDOXIM $C_6H_5.C(NOH).NHPh$. [136°]. Formed by boiling $C_6H_5.CS.NHPh$ with an alcoholic solution of hydroxylamine (Müller, *B.* 19, 1669). Needles (from water). Yields B'HCl. $ClCO_2Et$ forms $C_{14}H_{10}N_2O_2$ [167°].

DI-PHENYL-BENZAZIDINE $C_{19}H_{18}N_4$ *i.e.* $C_6H_5C(N.NHPh).NH.NHPh$. [179°]. Formed by the action of phenyl-hydrazine on $PhCCl_3$ or on the hydrochloride of benz-imido-ether dissolved in absolute alcohol (Pinner, *B.* 17, 182; Marckwald, *C. C.* 1888, 1410). Dark-red needles.

PHENYL-BENZENE *v.* DIPHENYL.

p-**Di-phenyl-benzene** $C_{18}H_{14}$ *i.e.* $C_6H_4Ph_2$. Mol. w. 230. [207°]. (c. 405°).

Formation.—1. A product of the action of sodium on an ethereal solution of *p*-di-bromo-benzene, or, better, of a mixture of *p*-di-bromo-benzene with bromine (Riese, *Z.* [2] 6, 192, 785; *A.* 164, 168).—2. Together with its isomeride, and other products, by passing the vapour of benzene, or of a mixture of benzene and toluene, through a red-hot tube (G. Schultz, *B.* 6, 415; *A.* 174, 230; 203, 118; Carnelley, *C. J.* 37, 712).—3. Together with the isomeride and other products, by the action of $AlCl_3$ on a mixture of MeCl and diphenyl (Adam, *Bl.* [2] 49, 97; *A. Ch.* [6] 15, 241).

Properties.—Needles (from benzene), or iridescent laminæ (by sublimation); insol. alcohol, v. sl. sol. HOAc. Its solution in benzene shows blue fluorescence. Conc. H_2SO_4 gives a dirty-green solution changing to purple. CrO_3 in HOAc oxidises it to diphenyl *p*-carboxylic [216°] and terephthalic acids. Does not form a compound with picric acid. Not volatile with steam. Yields $C_{18}Cl_{14}$ on exhaustive chlorination with $SbCl_5$ (Merz a. Weith, *B.* 16, 2884).

References.—BROMO- and TRI-CHLORO-DI-PHENYL-BENZENES.

Iso-di-phenyl-benzene $C_{18}H_{14}$. [85°]. (c. 370°). Formed as above. Slender prisms, v. sol. al.

cohol. Yields benzoic acid on CrO_3.

s-Tri-phenyl-benzene $C_{24}H_{18}$ *i.e.* $C_6H_3Ph_3$. Mol. w. 306. [171°]. (above 360°). Formed from acetophenone by treatment with P_2O_5, with alcoholic NH_3, or with dry HCl (Engler, *B.* 6, 638; 7, 1123). Formed also by heating $C_6H_3(C_6H_4.CO_2H)_3$ with KOH (Gabriel a. Michael, *B.* 11, 1007). It is also a by-product in the action of acetophenone on dimethylaniline in presence of $ZnCl_2$ (Döbner a. Petschoff, *A.* 242, 338). Trimetric crystals; *a*:*b*:*c* = ·566:1:·766, sl. sol. alcohol. Yields benzoic acid on oxidation by CrO_3 in HOAc (Mellin, *B.* 23, 2533). By exhaustive chlorination with $SbCl_5$ it yields per-chloro-tri-phenyl-benzene (Merz a. Weith, *B.* 16, 2883). On heating with I and red P at 275° it yields the crystalline dodeca-hydride $C_{24}H_{30}$ and finally oily $C_{24}H_{42}$ (Mellin, *B.* 23, 2534). Fuming H_2SO_4 at 100° forms a disulphonic acid, which yields the Ba salt $C_{24}H_{16}S_2O_6Ba$ crystallising in needles.

PHENYL-BENZENE-SULPHAZIDE *v.* *Phenyl-hydrazide* of BENZENE SULPHONIC ACID.

DI-PHENYL-BENZENYL-DI-UREA NHPh.CO.NH.CPh:N.CO.NHPh. [172°]. Formed from benzamidine hydrochloride, phenyl cyanate, and NaOHAq (Pinner, *B.* 22, 1607). Needles, insol. water, v. sl. sol. hot alcohol.

PHENYL-BENZIMIDO-ETHER $C_{15}H_{15}NO$ *i.e.* CPh(NPh).OEt. A product of the action of aniline on benzimido-ether (Lossen, *A.* 265, 138). Oil. Decomposed by conc. HClAq into EtCl and benzanilide.

PHENYL BENZOATE *v.* *Benzoyl derivative* of PHENOL.

PHENYL-BENZOIC ACID *v.* DIPHENYL-CARBOXYLIC ACID.

PHENYL-BENZOPHENONE $C_{19}H_{14}O$ *i.e.* [1:4] $C_6H_5.C_6H_4.CO.C_6H_5$. [104°]. V.D. 9·0. Formed by oxidation of *p*-benzyl-diphenyl with chromic acid (Goldschmiedt, *M.* 2, 437; Köller, *M.* 12, 501). Formed also from diphenyl, BzCl, and $AlCl_3$ (Wolf, *B.* 14, 2032). Scales, sol. alcohol. Yields benzophenone-*p*-carboxylic acid on further oxidation by CrO_3.

Oxim. [194°]. Needles. When HCl is passed into its solution in HOAc containing Ac_2O and the mixture heated in sealed tubes at 100°, it is converted into the isomeric $C_6H_5.C_6H_4.CO.NHC_6H_5$ [224°]. The oxim is reduced by sodium-amalgam to the corresponding amine $C_6H_5.C_6H_4.CH(NH_2).C_6H_5$ [77°].

Benzoyl derivative of the *Oxim* [193°]. Needles (from alcohol).

Phenyl-hydrazide. [144°]. Yellow needles (from dilute alcohol).

Di-phenyl-benzophenone $(C_6H_5.C_6H_4)_2CO$. [229°]. Formed by the action of $COCl_2$ on diphenyl in presence of $AlCl_3$ (Adam, *Bl.* [2] 47, 689; *A. Ch.* [6] 15, 259). Got also by oxidising $CH_2(C_6H_4Ph)_2$ (Weiler, *B.* 7, 1188). White needles, sol. acetone, v. sl. sol. alcohol. Not attacked by fuming HNO_3 or by H_2SO_4 and HNO_3 at 100°. By adding Na to its solution in alcohol-benzene it is reduced to $(C_6H_5.C_6H_4)_2CH.OH$, [151°], S. (ether) 5; S. (alcohol) 1·25 at 15°. Potash-fusion gives diphenyl-*p*-carboxylic acid [218°].

PHENYL-BENZOPHENONE CARBOXYLIC ACID $C_6H_4Ph.CO.C_6H_4.CO_2H$. [220°]. Formed from diphenyl, phthalic anhydride, and $AlCl_3$ (Kaiser, *A.* 257, 96). Needles. Yields an oxim ether MeA' [85°-90°].

PHENYL-BENZOYL is BENZOPHENONE.

PHENYL-BENZOYL-ACETIC ACID $CHBzPh.CO_2H$. *Methyl ether* MeA'. Form from de-oxybenzoin, NaOEt, and $ClCO_2$ (Rattner, *B.* 21, 1316). Oil, decomposed by d tillation into $C_2H_2Ph_2$, CO_2, and HOBz.

PHENYL-BENZOYL-BUTYRIC ACID $CHBzPh.CH_2.CH_2.CO_2H$. (β)-*Desyl-propion* *acid*. [136°]. Formed from deoxybenzoi NaOEt, and β-iodo-propionic ether (Knoevenag *B.* 21, 1344). Needles. Yields MeA' [6 and EtA' [84°].

The isomeric acid CHBzPh.CHMe.CO [215°], formed from β-bromo-propionic acid, less sol. alcohol and ether.

PHENYL-BENZOYL-CARBINOL *v.* BENZOÏ

PHENYL-BENZOYL-PROPIONIC ACID $CHBzPh.CH_2.CO_2H$. [156°]. Formed from d oxybenzoin, NaOEt, and chloro-acetic eth (Meyer a. Oelkers, *B.* 21, 1295; Knoevenage *B.* 21, 1344). Small tables (from alcohol).

Di-phenyl-benzoyl-propionic acid $CH_2Bz.CPh_2.CO_2H$. [183°]. Got by the action alcoholic potash on the lactone of oxy-tri-pheny crotonic acid (Japp a. Klingemann, *B.* 22, 2882 Yields a phenyl-hydrazide $C_{28}H_{22}N_2O$ [185° and an oxim $C_{22}H_{19}NO_2$ [152°].

PHENYL-BENZYL ALCOHOL $C_{13}H_{12}O$ *i.* $C_6H_4Ph.CH_2OH$. Got from $C_6H_4Ph.CH_3$ by treatment with Br and alcoholic potash; the resultin syrupy $C_6H_4Ph.CH_2OEt$ being treated with H (Adam, *Bl.* [2] 49, 97). Syrup.

PHENYL-BENZYL-AMIDO-DI-PHENYL-METHANE $C_{26}H_{23}N$ *i.e.* $CH_2Ph.C_6H_4NPh.C_7H$ Formed by heating NPh_2H (1 mol.) with benzy chloride (2 mols.) and $ZnCl_2$ at 210° (Meldola *C. J.* 41, 200). Solid; *v.* sol. ether, insol. alcoho and HOAc.

PHENYL-BENZYL-AMINE *v.* BENZYL-ANILINE.

Nitrosamine $C_7H_7NPh.NO$. [58°]. Needle (Antrick, *A.* 227, 360). Yields benzyl-anilin and benzylidene-aniline on treatment wit alcoholic HCl (O. Fischer, *A.* 241, 328).

Phenyl-di-benzyl-amine *v.* DI-BENZYL-ANILINE.

Di-phenyl-benzyl-amine $NPh_2.CH_2Ph$. [87°] Got from $C_6H_5.CSNPh_2$, zinc-dust, and HClAq (Bernthsen a. Trompetter, *B.* 11, 1761; *cf.* Wilm a. Girard, *B.* 8, 1196). Needles, sl. sol. cold alcohol. Yields a green dye on heating with HClAq and arsenic acid (Meldola, *B.* 14, 1385).

DI-PHENYL-DI-BENZYL-TETRAZONE $NPh(CH_2Ph).N:N.NPh(CH_2Ph)$. [109°]. Formed from (α)-phenyl-benzyl-hydrazine, $CHCl_3$, and HgO (Michaelis a. Philips, *A.* 252, 290). Needles.

PHENYL-BENZYL-CARBINOL $C_{14}H_{14}O$ *i.e.* $CH_2Ph.CH(OH).C_6H_5$. *Toluylene hydrate.* [42°]. Formed by reducing deoxybenzoin, and by the action of alcoholic potash on the same body (Limpricht a. Schwanert, *A.* 155, 62; Goldenberg, *A.* 174, 332; Zagoumenny, *A.* 184, 163; Anschütz, *A.* 261, 298). Formed also [62°] by the action of nitrous acid on $CH_2Ph.CHPh.NH_2$ (Leuckart, *B.* 22, 1410). Long slender needles (from alcohol), insol. water. Reduced by HIAq to dibenzyl. Yields a liquid acetyl derivative.

PHENYL BENZYL ETHER *v.* *Phenyl ether* of BENZYL ALCOHOL.

[illegible]-PHENYL-THIO-UREA [illegible] [91°]. Formed from ethyl-thiocarbimide and benzyl-aniline in alcohol (Dixon, *C. J.* [illegible], 566). Rectangular prisms, insol. cold water, v. e. sol. boiling alcohol.

An isomeride [91° uncor.] formed from benzyl-thiocarbimide and ethyl-aniline crystallises in oblique prisms grouped in rosettes.

PHENYL-BENZYL-HYDRAZINE $C_{13}H_{14}N_2$ *i.e.* $CH_2Ph.NPh.NH_2$. [26°]. Formed from sodium phenyl-hydrazine and benzyl chloride, and got also by reduction of phenyl-benzyl-nitrosamine (Antrick, *A.* 227, 361; Michaelis a. Philips, *A.* 252, 286). Needles (containing aq), decomposed by heat. Benzoic aldehyde forms $CH_2Ph.NPh.N{:}CHPh$. [111°]. In benzene solution it gives with $SOCl_2$ the thionyl compound $C_7H_7NPh.N{:}SO$ [65°] (Michaelis a. Ruhl, *A.* 270, 122). $C_6H_5PCl_2$ forms $C_7H_7NPh.N{:}PC_6H_5$ [141°], crystallising from ether in needles.—B'HCl. [167°]: colourless needles. Benzene phosphinate $B'C_6H_5PH_2O_2$ [108°] (Michaelis, *A.* 270, 135).

Acetyl derivative. [121°]. Scales.

Benzylo-chloride $(C_7H_7)_2NPhCl.NH_2$. [154°].

PHENYL-BENZYLIDENE-ALLYL-HYDRAZINE $NPh(C_3H_5).N{:}CHPh$. [52°]. Formed from phenyl-allyl-hydrazine and benzoic aldehyde (Michaelis a. Claesson, *B.* 22, 2237). Needles, v. sol. ether and hot alcohol.

PHENYL-BENZYLIDENE-AMINE *v.* BENZYLIDENE-ANILINE.

Phenyl-benzylidene-diamine $C_6H_5.CH(NH_2)(NHPh)$. [115°]. Formed by reduction of phenyl-benzamidine with zinc and HCl (Bernthsen a. Szymanski, *B.* 13, 917). Small crystals.—B'HCl. [224°]. Thick prisms.—$B'_2H_2PtCl_6$: spikes or plates.

DI-PHENYL-BENZYLIDENE-ETHYLENE-DIAMINE $CHPh{<}\substack{NPh\\NPh}{>}C_2H_4$. [137°]. Formed from benzoic aldehyde and di-phenyl-ethylene-diamine (Moos, *B.* 20, 732). Needles, split up by dilute HCl into the parent bodies.

PHENYL-BENZYLIDENE-ETHYL-HYDRAZINE $PhNEt.N{:}CHPh$. [59°]. Formed from benzoic aldehyde and phenyl-ethyl-hydrazine (Michaelis a. Philips, *A.* 252, 272).

PHENYL-BENZYLIDENE-HYDRAZINE *v.* *Phenyl-hydrazide* of BENZOIC ALDEHYDE.

DI-PHENYL-BENZYLIDENE-DI-INDOLE $CHPh(C_{14}H_{10}N)_2$. [268° uncor.]. Formed from benzoic aldehyde and $C_6H_4{<}\substack{CH\\NH}{>}CPh$ (E. Fischer a. Schmidt, *B.* 21, 1074). Slender leaflets, v. sl. sol. hot alcohol.

PHENYL-BENZYL-INDOLE $C_{21}H_{17}N$ *i.e.* $C_6H_4{<}\substack{C(C_7H_7)\\NH}{>}CPh$. [101°]. Formed by heating the phenyl-hydrazide of di-benzyl ketone with alcoholic HCl (Trenkler, *A.* 248, 112). Hexagonal prisms (from hot ligroin). Does not give the pine-wood reaction.

PHENYL BENZYL KETONE $C_{14}H_{12}O$ *i.e.* $C_6H_5.CH_2.CO.C_6H_5$. *Desoxybenzoin. Deoxybenzoin.* Mol. w. 196. [60°]. (322° cor.). (177·6° at 12 mm.) (Anschütz a. Berns, *B.* 20, 1392).

Formation.—1. By the action of zinc and HCl on benzoin (Zinin, *A.* 119, 179; 126, [illegible]; [illegible] 4, 718; V. Meyer, *B.* 21, 1296; Wachter, *B.* 25, 1728).—2. By passing benzoin over heated zinc-dust (Limpricht a. Schwanert, *A.* 155, 59).—3. By heating bromo-di-phenyl-ethylene with water at 190° (L. a. S.).—4. By distilling a mixture of calcium benzoate and calcium phenyl-acetate (Radziszewski, *B.* 6, 489; 8, 756).—5. By the action of $AlCl_3$ on a mixture of phenyl-acetyl chloride and benzene (Graebe a. Bungener, *B.* 12, 1079).—6. From phenyl-acetic acid, benzene, and P_2O_5 (Zincke, *B.* [illegible], 1771).—7. By the action of alcoholic ammonium sulphide (or KHS) on benzil (Zinin, *J. pr.* 33, 35; Jena, *A.* 155, 87).—8. By dissolving s-di-phenyl-acetylene in H_2SO_4 and adding water (Béhal, *Bl.* [2] 49, 387).

Properties.—White plates (from alcohol); sl. sol. hot water, volatile with steam.

Reactions.—1. On heating with *alcoholic potash* it yields phenyl-benzyl-carbinol and 'di-ethyl carbobenzonic' acid $C_{18}H_{18}O_2$ [100°], which gives EtA' (209° at 11 mm.) (Zagoumenny, *A.* 184, 163; Anschütz, *A.* 261, 298). The acid $C_{18}H_{18}O_2$ is converted by P and HI into an isomeric acid [184°], by HNO_3 (S.G. 1·18) into $C_{18}H_{16}O_3$ [128°], by conc. HNO_3 into $C_{18}H_{16}(NO_2)_2O_2$ [156°], and by potash-fusion into β-benzyl-isobutyric acid.—2. KOH in *propyl alcohol* at 150° forms $C_{20}H_{22}O_2$ [90°] and also an isomeride [139°] which yields $C_{20}H_{20}(NO_2)_2O_2$ [176°].—3. KOH in *isobutyl alcohol* at 140° forms 'di-isobutyl-carbobenzonic' acid $C_{22}H_{26}O_2$ [148°], S. (alcohol) 5. The homologous isoamyl compound $C_{24}H_{30}O_2$ [160] may be got in like manner.—4. Reduced by HI to di-phenyl-ethylene and di-phenyl-ethane.—5. *Sodium-amalgam* reduces it to $C_{28}H_{26}O_2$ and finally to phenyl-benzyl-carbinol.—6. *Nitric acid* (S.G. 1·2) yields benzil, nitro-benzil, and *p*-nitro-benzoic acid. Conc. HNO_3 (S.G. 1·475) at 0° forms $C_{14}H_{11}(NO_2)O$ [142°], whence $C_{14}H_{11}(NH_2)O$ [95°]. The nitro- and amido-compounds yield oxims melting at 107° and 141° respectively. Fuming HNO_3 (S.G. 1·51) at 0° forms three isomeric di-nitro- derivatives [116°], [126°] and [155°] (Golubeff, *B.* 18, 2403; *J. R.* 18, 23).—7. *Bromine* forms $C_{14}H_{11}BrO$ [55°] (Knoevenagel, *B.* 21, 1355) and $C_6H_5.CO.CBr_2.C_6H_5$ [112°].—8. PCl_5 yields $CHPh{:}CClPh$.—9. *Alcoholic potash* and *benzoic* aldehyde form benzamarone $C_{35}H_{28}O_3$ [315°] (Japp a. Klingemann, *B.* 21, 2934; *cf.* Zinin, *Z.* 1871, 127).—10. NaOEt and nitrous acid yield the mono- oxim of benzil.—11. NaOEt and $CSCl_2$ yield golden $(C_6H_5.C(CS).CO.C_6H_5)_x$ [286°] (Bergreen, B. 21, 350).—12. NaOEt and MeI yield phenyl phenyl-ethyl ketone $C_6H_5.CO.CHMePh$. Other alkyl iodides act in like manner (V. Meyer, *B.* 21, 1295).—13. Sodium acting on a benzene solution in absence of air forms $C_6H_5.CO.CHNa.C_6H_5$, a very hygroscopic yellow substance converted by CO_2 into an acid, whence hydroxylamine forms $\substack{CPh\ {:}N\\CHPh.CO}{>}O$ [160°] (Beckmann a. Paul, *A.* 266, 22).—14. $CSCl_2$ or CS_2 forms desaurin [illegible] which is fiery yellow, sparingly soluble, and yields a violet solution in H_2SO_4 (Bergreen a. Meyer, *B.* 21, 353; Meyer a. Wege, *B.* 24, 3535; Wachter, *B.* 25, 1727). HNO_3 and H_2SO_4 convert desaurin into $C_{14}H_9SN_3O_7$? [60°]. Fuming HNO_3 forms $C_{14}H_9SN_2O_{10}$ [60°] and *m*-nitro-benzoic acid. Desaurin when heated for a long time with aniline yields phenyl benzyl ketone, tri-phenyl-guanidine, and H_2S.

Oxim $C_6H_5.CH_2.C(NOH).C_6H_5$. [98°].

Phenyl-hydrazide $CH_2Ph.C(N_2HPh).Ph$. [106°]. Needles (from alcohol) (Ney, *B.* 21, 2447).

PHENYL BENZYL KETONE-*o*-CARBOXYLIC ACID $C_{15}H_{12}O_3$ *i.e.* $C_6H_5.CO.CH_2.C_6H_4.CO_2H$. *Deoxybenzoïn-carboxylic acid.* [168]. Formed by heating isobenzylidene-phthalide with NaOH (Gabriel, *B.* 18, 2446). Needles, v. sol. alcohol. Reduced by sodium-amalgam to $C_6H_5.CH(OH).CH_2.C_6H_4.CO_2H$. Ammonia forms isobenzylidene-phthalimidine. Hydroxylamine hydrochloride in alcoholic solution at 100° forms  $C_6H_4<{CH_2.CPh \atop CO-O}>N$ [189°]. AgA′: pp.

Anhydride v. Isobenzylidene-phthalide.

Methylamide $CH_2Bz.C_6H_4.CO.NHMe$. 44°]. Formed from isobenzylidene-phthalide nd methylamine in alcohol at 100° (Gabriel, . 20, 2866). White needles.

Phenyl benzyl ketone *o*-carboxylic acid $H_5.CH_2.CO.C_6H_4.CO_2H$. *Deoxybenzoïn-carboxylic acid.* [75°]. Formed by boiling benzidene-phthalide with KOHAq (Gabriel a. ichael, *B.* 11, 1018). Prisms (containing aq). AgA′: crystalline pp.

Anhydride v. Benzylidene-phthalide.

Amide $CH_2Ph.CO.C_6H_4.CO.NH_2$. [166°]. ormed from benzylidene-phthalide and alcolic NH_3 at 100° (Gabriel, *B.* 18, 2434). eedles, sol. hot water, converted into benzylidene-phthalimidine by boiling with HOAc.

Ethylamide $CH_2Ph.CO.C_6H_4.CO.NHEt$. [140°]. Formed from benzylidene-phthalide and alcoholic $NEtH_2$ at 100° (Gabriel, *B.* 18, 1258, 2434). Converted by boiling HOAc into  $C_6H_4<{C(CHPh) \atop CO}>NEt$. [77°]. Hydroxylamine forms  $C_6H_4<{C(CH_2Ph) \atop CO-O}>N$ [177°], which is also formed by the action of hydroxylamine on phenyl benzyl ketone carboxylic acid.

Phenyl benzyl ketone dicarboxylic acid $C_6H_4(CO_2H).CO.CH_2.C_6H_4.CO_2H$. [239°]. Formed together with an isomeride [250°] by heating phenyl-acetic-*o*-carboxylic acid with phthalic anhydride and NaOAc at 190° (Ephraim, *B.* 24, 2821). Needles. Gaseous HCl acting on its alcoholic solution forms the anhydride  $C_6H_4<{CH_2\ .CO \atop CO.O.CO}>C_6H_4$. [260°]. Hydroxylamine yields  $C_6H_4<{CH_2- \atop CO.O.N}>C.C_6H_4.CO_2H$ [280°] crystallising in needles. Alcoholic NH_3 forms crystalline $C_{16}H_{11}NO_3$.

PHENYL-BENZYL-METHYL-AMINE $C_{14}H_{15}N$ *i.e.* $NMePh.CH_2Ph$. [306°] (Nölting, *M. S.* [3] 13, 89).

Methylo-chloride B′MeClaq. [110°]. Formed from di-methyl-aniline and benzyl chloride (Michler, *B.* 10, 2079). Tables, v. sol. water and alcohol. Converted by successive treatment with Ag_2SO_4 and baryta into a syrupy hydroxide, which is split up on distillation into benzyl alcohol and di-methyl-aniline.

PHENYL-BENZYL-METHYL-THIO-UREA $C_{15}H_{16}N_2S$ *i.e.* $NPhMe.CS.NHC_7H_7$. [85°]. Formed from benzyl-thiocarbimide and methyl-aniline (Dixon, *C. J.* 59, 568). Prisms.

Isomeride $NHMe.CS.NPhC_7H_7$. [illegible]. Formed by boiling methyl-thiocarbimide with benzyl-aniline in alcoholic solution (D.). Tufts of white prisms, v. sl. sol. hot water.

PHENYL-BENZYL-METHYL-UREA $CH_2Ph.NH.CO.NPhMe$. [84°]. Formed from $CH_2Ph.NH.COCl$ and methyl-aniline (Kühn a. Riesenfeld, *B.* 24, 3817). V. sol. alcohol.

BENZYL-PHENYL-NITROSAMINE $C_7H_7NPh(NO)$. *Nitrosamine of benzyl-aniline.* [58°]. Formed from benzyl-aniline (10 g.), alcohol (125 c.c.), H_2SO_4 (6 c.c.), and $NaNO_2$ in the cold, the product being poured into water (500 c.c.) (Antrick, *A.* 227, 360). Pale-yellowish needles, v. sol. alcohol and ether.

PHENYL-BENZYL-OXIDE *v. Phenyl ether* of Benzyl alcohol.

PHENYL-BENZYL-PHOSPHINE? $CH_2Ph.PHPh$ or $C_{25}H_{24}P_2$. [171°]. Formed by heating $C_6H_5PCl_2$ with benzyl chloride and zinc (Michaelis a. Gleichmann, *B.* 15, 1961). Needles, converted by successive treatment with chlorine and alkalis into $C_{13}H_{13}PO$ or $C_{25}H_{24}P_2O_2$ [155°].

Di-phenyl-benzyl-phosphine dichloride $C_7H_7PCl_2(C_6H_5)_2$. [187°]. Formed from $(C_6H_5)_2PCl$ and benzyl chloride at 180° (Dörken, *B.* 21, 1506; *cf.* Michaelis, *B.* 18, 2117). Prisms.

Di-phenyl-benzyl-phosphine oxide $C_7H_7PO(C_6H_5)_2$. [196°]. Formed by decomposing the preceding body with water. Yields a tri-nitro- derivative [206°].

DI-PHENYL-DI-BENZYL-SUCCINIC ACID. *Nitrile.* $CN.CPh(CH_2Ph).CPh(CH_2Ph).CN$. [235°]. Formed from $CN.CNaPh(CH_2Ph)$ and I (Chalanay a. Knoevenagel, *B.* 25, 290). White crystalline powder, sl. sol. alcohol.

PHENYL BENZYL SULPHONE $C_{13}H_{12}SO_2$ *i.e.* $C_6H_5.SO_2.CH_2Ph$. [148°]. Formed from $C_6H_5.SO_2Na$ and benzyl chloride (Knoevenagel, *B.* 21, 1344). Sl. sol. ether, m. sol. alcohol.

DI-PHENYL-BENZYL-THIOSEMICARBAZIDE $NPh(C_7H_7).NH.CS.NHPh$. [150°]. Formed from phenyl-benzyl-hydrazine in alcohol and phenyl-thiocarbimide (Michaelis a. Philips, *A.* 252, 289). Crystals, v. sol. hot alcohol.

PHENYL-BENZYL-THIO-UREA $C_{14}H_{14}N_2S$ *i.e.* $NHPh.CS.NHCH_2Ph$. [154°]. Formed by mixing alcoholic solutions of benzylamine and phenyl-thiocarbimide (Dixon, *C. J.* 55, 300). Prisms (from alcohol), sl. sol. CS_2.

Phenyl-di-benzyl-thio-urea $C_{21}H_{20}N_2S$ *i.e.* $NPh(C_7H_7).CS.NH.C_7H_7$. [103°]. Formed from phenyl-thiocarbimide and benzyl-aniline (D.). White prisms, v. sl. sol. hot water.

PHENYL-BENZYL-*p*-TOLYL-BIURET $C_{22}H_{21}N_3O_2$. [95°–104°]. Needles (from dilute alcohol) (Kühn a. Henschel, *B.* 21, 504).

PHENYL-BENZYL-UREA $C_{14}H_{14}N_2O$ *i.e.* $NHPh.CO.NHCH_2Ph$. [168°]. Formed by mixing benzyl cyanate with aniline (Letts, *C. J.* 25, 448). Needles, v. sol. alcohol.

Phenyl-di-benzyl-urea $C_{21}H_{20}N_2O$. [128°]. Got from $(C_7H_7)_2N.COCl$ and aniline (Hammerich, *B.* 25, 1819). Silky needles (from alcohol).

PHENYL-BISMUTHINE *v.* vol. i. p. 517.

PHENYL-BIURET $C_8H_9N_3O_2$ *i.e.* $NHPh.CO.NH.CO.NH_2$. Formed from phenyl-urea and PCl_5 (Weith, *B.* 10, 1744). Crystals.

s-Di-phenyl-biuret $NH(CO.NHPh)_2$. [210°]. Formed by boiling allophanic ether, biuret, or [illegible] ether, with aniline (Hofmann, *B.* [illegible] 250; Leuckhart, *J. pr.* [2] 21, 27). Formed also by the action of phenyl cyanate on phenyl-urea (Kühn a. Henschel, *B.* 21, 504). Needles.

u-Di-phenyl-biuret NH$_2$.CO.NPh.CO.NHPh. [165°]. Got from di-phenyl dicyanate and alcoholic NH$_3$ (Hofmann). Prisms, sol. alcohol.

s-Tri-phenyl-biuret NPh(CO.NHPh)$_2$. [148°]. Formed from di-phenyl dicyanate and aniline (H.) and by heating phenyl cyanate with di-phenyl-urea at 150°. Prisms (from alcohol). An isomeride [105°] was got by Schiff (*B.* 8, 651) by distilling phenyl-carbamic ether.

References.—Di-bromo-di- and Oxy- phenyl-biuret.

PHENYL-BORATE $C_6H_5BO_2$. Formed by heating phenol (3 pts.) with B_2O_3 (2 pts.), or, better, by heating tri-phenyl borate with alcohol at 150° (Schiff, *A. Suppl.* 5, 202). Sticky mass.

Tri-phenyl borate $(C_6H_5)_2B_2O_5$. Formed by boiling phenol with B_2O_3. Glassy mass, decomposed by hot water.

Tetra-phenyl diborate $(C_6H_5)_4B_2O_5$. S.G. [illegible] 1·124. Formed, with the preceding body, by heating $C_6H_5BO_2$ at 350°. Thick oil, quickly decomposed by water.

Phenyl-boric acid $C_6H_5.B(OH)_2$. [204°]. Formed from $C_6H_5BCl_2$ and water (Michaelis a. Becker, *B.* 15, 181). Needles, sol. alcohol, ether, and hot water. Powerful antiseptic, with but slight physiological action. With $HgCl_2$ it gives a pp. of PhHgCl. Reduces ammoniacal $AgNO_3$, forming a mirror. On heating, it yields the oxide C_6H_5BO [190°] (above 360°), which forms crystals, sol. alcohol.

Salts.—NaA″: dimetric tables.—$CaH_2A''_2$: crystals.—AgHA″: yellow pp.

Ethyl ether Et_2A''. (176°). Oil.

Chloride v. vol. i. p. 531.

PHENYL BROMIDE *v.* Bromo-benzene.

PHENYL BROMO-ALLYL OXIDE *v. Bromo-allyl derivative* of Phenol.

PHENYL BROMO-BENZYL KETONE $C_6H_5.CO.CHBrPh$. [55°]. Got by brominating phenyl benzyl ketone (Knoevenagel, *B.* 21, 1355).

PHENYL BROMO-BUTYL KETONE $C_6H_5.CO.CH_2.CH_2.CH_2.CH_2Br$. [61°]. Formed from phenyl oxy-butyl ketone anhydride or its carboxylic acid and conc. HBrAq (W. H. Perkin, jun., *C. J.* 51, 732; *B.* 19, 2559). Six-sided plates, v. sol. alcohol. Converted by warm alcoholic potash into the parent

$$CH_2{<}{\begin{matrix}CH:CPh\\CH_2.CH_2\end{matrix}}{>}O.$$

Phenyl di-bromo-butyl ketone $C_6H_5.CO.CH_2.CH_2.CHBr.CH_2Br$. Formed from allyl-acetophenone and Br (Perkin, *C. J.* 45, 188). Oil. Bromine yields $C_{11}H_{11}Br_3O$ [122°] crystallising from dilute alcohol in prisms.

PHENYL BROMO-ETHYL KETONE $C_6H_5.CO.C_2H_4Br$. Formed from phenyl ethyl ketone and Br in CS_2 (Pampel a. Schmidt, *B.* 19, 2897). Oil with pungent odour.

PHENYL BROMO-ETHYL OXIDE *v. Bromo-ethyl derivative* of Phenol.

PHENYL BROMO-ETHYL SULPHONE $C_6H_5.SO_2.CHMeBr$. [50°]. Formed by boiling an aqueous solution of the Na salt of the acid $C_6H_5.SO_2.CMeBr.CO_2H$ [184°], which is got by bromination of $C_6H_5.SO_2.CMeH.CO_2H$ (Otto, *J. pr.* [2] 40, 550). Rectangular tables.

PHENYL BROMO-IMESATIN *v.* Isatin.

PHENYL-BROMO-METHENYL-DI-ETHYL TRI-SULPHONE $C_6H_5.SO_2.CBr(SO_2.C_2H_5)_2$. [135°]. Formed by bromination of the sulphone $CH(SO_2Ph)(SO_2Et)_2$ (Laves, *B.* 25, 354). Plates (from alcohol) or needles (from Aq).

TRI-PHENYL-BROMO-METHENYL TRI-SULPHONE $CBr(SO_2Ph)_3$. [255°]. Got by brominating $CH(SO_2Ph)_3$ (Laves, *B.* 25, 351). Amorphous insoluble pp.

PHENYL BROMO-METHYL KETONE *v.* ω-Bromo-acetophenone.

PHENYL BROMO-METHYL SULPHONE $C_6H_5.SO_2.CH_2Br$. [48°]. Formed, together with $C_6H_5.SO_2.CHBr_2$ [75°], from $C_6H_5.SO_2.CH_2.CO_2H$ and Br (Otto, *J. pr.* [2] 40, 542). Both compounds form monoclinic tables, v. sol. hot alcohol.

PHENYL BROMO-(α)-NAPHTHYL KETONE $C_6H_5.CO.C_{10}H_6Br$. [98°]. Formed by bromination of phenyl (α)-naphthyl ketone (Elbs a. Steinike, *B.* 19, 1966). Yields a crystalline di-nitro- derivative decomposing at about 90°. Yields $C_{17}H_{10}Br(SO_3H)$ [116°] on sulphonation.

PHENYL-BROMO-NITRO-METHANE *v.* Bromo-nitro-toluene.

PHENYL-BROMO-DI-NITRO-PHENYL-AMINE *v.* Bromo-di-nitro-di-phenyl-amine.

PHENYL-BROMO-NITRO-PHENYL-HYDRAZINE $C_6H_5.N_2H_2.C_6H_3Br(NO_2)$. [3:1:4], [165°]. Formed from phenyl-hydrazine and $C_6H_3Br(NO_2)_2$ (Willgerodt, *J. pr.* [2] 37, 458). Red needles (from alcohol).

PHENYL-p-BROMO-PHENYL-HYDRAZINE $C_6H_5.N_2H_2.C_6H_4Br$. [115°]. Formed by reduction of $C_6H_5.N_2.C_6H_4Br$ by alcoholic ammonium sulphide (Janovsky, *B.* 20, 364). Tables.

PHENYL BROMO-PHENYL KETONE *v.* Bromo-benzophenone.

DI-PHENYL BROMO-PROPYLENE DISULPHONE $C_3H_5Br(SO_2Ph)_2$. [160°]. Got from $CH_2Br.CHBr.CH_2Br$ and NaSPh in alcohol (Stuffer, *B.* 23, 1411). Needles.

PHENYL BROMO-PROPYL KETONE $C_6H_5.CO.CH_2.CH_2.CH_2Br$. [39°]. Formed from 'benzoyl-trimethylene carboxylic' acid and fuming HBr (W. H. Perkin, jun., *C. J.* 47, 844). Crystalline mass, v. sol. alcohol.

PHENYL-BUTANE *v.* Butyl-benzene.

Di-phenyl-butane $CH_2Ph.CH_2.CH_2.CH_2Ph$. [52°]. Formed by heating di-phenyl-butylene with HI and P at 250° (Freund a. Immerwahr, *B.* 23, 2858). Crystals, v. sol. alcohol.

Di-phenyl-butane CHMePh.CHMePh. [123·5°]. Formed by the action of zinc-dust or Na on CHMePhBr (Radziszewski, *B.* 7, 142; Engler, *B.* 7, 1127). Needles (from ether).

Di-phenyl-butane CPh_2MeEt. [128°]. Formed from $CPh_2Me.CO.CH_3$, phosphorus, and HI (Zincke a. Thörner, *B.* 11, 1990). Tables or prisms, m. sol. alcohol.

Di-phenyl-butane $CH_3.CH(CH_2Ph)_2$. (300°). Formed by heating acetophenone with HIAq and P at 180° (Graebe, *B.* 7, 1627). Oil.

References.—Amido-, Tri-chloro-, and Tri-chloro-di-nitro- and Oxy- phenyl-butanes.

PHENYL-BUTANE TRICARBOXYLIC ACID. *Ethyl ether* $C_6H_5.CH_2.C(CO_2Et)_2.CHMe.CO_2Et$. (338° cor.). S.G. [illegible] 1·1008. μ_D 1·4850 at 20°. Formed from sodium-propane tri-carboxylic ether and benzyl chloride (Bischoff a. Mintz, [illegible]). The free acid gives benzyl-methyl-succinic acid on heating.

Di-phenyl-butane dicarboxylic acid $C_6H_4(CO_2H).CH_2.CH_2.CH_2.CH_2.C_6H_4.CO_2H$. [193°]. Formed by heating $C_2H_4(CO.C_6H_4.CO_2H)_2$ with HIAq and P at 160° (Gabriel a. Michael, *B.* 10, 2208). Nodules, insol. water.—Ag_2A'': pp.

PHENYL-BUTENYL ALCOHOL $C_{10}H_{12}O$ *i.e.* $C_6H_5.C_2H(OH).C_2H_3$. (225°). S.G. 12 ·985. Got from its acetyl derivative (228°-230°), formed from CPh:CEt by successive treatment with HBr and AgOAc (Morgan, *C. J.* 29, 162). Liquid.

PHENYL-BUTENYL KETONE $CH_2:CH.CH_2.CH_2.CO.Ph$ (235°-238°) at 710 mm. Obtained from allyl-benzoyl-acetic acid and boiling dilute alcoholic potash (W. H. Perkin, jun., *C. J.* 45, 187). Oil, smelling like camphor. Insol. water. Combines with Br. Excess of Br added to a glacial acetic acid solution forms bromo-phenyl-butenyl ketone dibromide, [122°].

PHENYL-BUTINENE $C_{10}H_{10}$ *i.e.* CPh:CEt. *Phenyl-ethyl-acetylene.* (202°). S.G. 21 ·923. Formed from sodium phenyl-acetylene and EtI (Morgan, *C. J.* 29, 162). Liquid.

Phenyl-butinene $C_{10}H_{10}$. (185°-190°). Got from $CH_2Ph.CH_2.CHBr.CH_2Br$ and alcoholic potash at 180° (Aronheim, *A.* 171, 231). Liquid.

Di-phenyl-butinene CHPh:CH.CH:CHPh. [148°]. (320°-340°). Obtained by heating $CHPh:CH.CH:CPh.CO_2H$ (Rebuffat, *G.* 15, 107; 20, 154). Micaceous plates.

References.—AMIDO- and OXY-PHENYL-BUTINENES.

PHENYL-BUTINENE DICARBOXYLIC ACID $CHPh:CH.CH:C(CO_2H)_2$. [208°]. Formed by heating cinnamic aldehyde with malonic acid and HOAc at 100° (Stuart, *C. J.* 49, 366). Needles; gives off CO_2 when melted.

DI-PHENYL-DI-BUTINYL KETONE $CO(CH:CH.CH:CHPh)_2$. [142°]. Formed from cinnamic aldehyde, acetone, and NaOHAq (Diehl a. Einhorn, *B.* 18, 2325). Needles.

PHENYLBUTINYL METHYL KETONE $CH_3.CO.CH:CH.CH:CHPh$. [68°]. Formed from cinnamic aldehyde, acetone, and NaOHAq (Diehl a. Einhorn, *B.* 18, 2321). Plates (from ether). Yields a dibromide [174°] and a phenyl-hydrazide [180°] crystallising in plates.

DI-PHENYL-BUTONENE $C_{16}H_{12}$. *Phenyl naphthalene?* [101°]. (346°). Formed from di-oxy-ethyl-benzene (styrolene alcohol) by treatment with H_2SO_4 (16 pts.) and water (9 pts.) (Zincke a. Breuer, *A.* 226, 23). Plates, v. sol. alcohol. Oxidised by $K_2Cr_2O_7$ and HOAc to $C_{16}H_{10}O_2$ [110°], which crystallises in golden needles, m. sol. alcohol, and is readily polymerised by exposure of its solution to light, yielding two polymerides [207°] and [225°-229°]. The quinone $C_{16}H_{10}O_2$ is reduced by $SnCl_2$ to the hydroquinone $C_{16}H_{10}(OH)_2$ [93°] which gives $C_{16}H_{10}(OAc)_2$ [152°]. The quinone $C_{16}H_{10}O_2$ is reduced by aqueous SO_2 at 120° to the quinhydrone $C_{32}H_{22}O_4$ [133°]. On heating the quinone with NaOHAq it is converted into the oxy-quinone $C_{16}H_9(OH)O_2$ [144°], which gives $C_{16}H_9(OAc)O_2$ [111°], and may be reduced to the oxy-quinhydrone [1[illegible]°], and the oxy-hydroquinone [73°]. The oxyquinone is oxidised by alkaline $KMnO_4$ to an acid $C_9H_8O_4$ [177°-197°] whence $BaA''2aq$, K_2A'', $Cu_2(OH)_2A''6aq$, and Ag_2A''. Alcoholic NH_3 converts the quinone into [illegible] while ethylamine, aniline, *o-* and *p-* toluidine, and naphthylamine form compounds melting at [130°], [158°], [108°], [155°], and [148°] respectively. The compound $C_{16}H_{11}NO_2$ forms an acetyl derivative [201°], and on treatment with aqueous SO_2 at 140° gives the oxyquinone and a substance $C_{32}H_{22}O_5$ [187°].

PHENYL-*sec*-BUTYL-ALCOHOL $C_{10}H_{14}O$ *i.e.* $C_6H_5.CH_2.CH_2.CH(OH).CH_3$. [68°]. Formed by reducing styryl methyl ketone with sodium-amalgam (Engler a. Leist, *B.* 6, 255). Crystals.

Phenyl-*tert*-butyl alcohol $C_{10}H_{14}O$ *i.e.* $C_6H_5.CH_2.CMe_2.OH$. [22°]. (220°-230°). Got from phenyl-acetyl chloride and $ZnMe_2$ followed by water (Popoff, *B.* 8, 768). Needles.

Tri-phenyl-*tert*-butyl-alcohol $CPh_3.CMe_2OH$. (above 260°). Formed from $CCl_3.CMe_2.OH$, benzene, and $AlCl_3$ (Willgerodt a. Genieser, *J. pr.* [2] 37, 368).

DI-PHENYL-DI-ISOBUTYL-TETRAZONE $C_4H_9NPh.N:N.NPh.C_4H_9$. [107°]. Got from phenyl-isobutyl-hydrazine in ether by treatment with HgO (Michaelis a. Philips, *A.* 252, 284).

PHENYL-BUTYLENE $C_{10}H_{12}$ *i.e.* $C_6H_5.CH_2.CH:CH.CH_3$ or $C_6H_5.CH_2.CH_2.CH:CH_2$. (177°). S.G. 15·5 ·915. Formed from benzyl chloride, allyl iodide, and Na (Aronheim, *B.* 5, 1068; *A.* 171, 219). The same hydrocarbon appears to be formed by distilling the lactonic acid of γ-oxy-γ-phenyl-s-di-methyl-succinic acid (Penfield, *A.* 216, 125). Oil, yielding a liquid dibromide. KNO_2 and HOAc form $C_{10}H_{12}N_2O_3$, which gives on reduction a base $C_{10}H_{15}NO$, whence B'HCl and $B'_2H_2PtCl_6$ (Tönnies, *B.* 11, 1511).

(α)-Phenyl-butylene $C_6H_5.CH:CH.CH_2.CH_3$. (186°). Formed by distilling $C_{10}H_{11}Br$ obtained by bromination of *n*-butyl-benzene (Radziszewski, *B.* 9, 260). Forms a dibromide $C_{10}H_{12}Br_2$ [71°] crystallising in white needles. Probably identical with the phenyl-butylene (187°) obtained by Perkin (*C. J.* 32, 667; 35, 140) from phenyl-angelic acid by successive treatment with HBr and Na_2CO_3Aq or with HI and KOH. Perkin's phenyl-butylene forms a crystalline dibromide [67°] converted by alcoholic potash into oily $C_{10}H_{11}Br$, which forms oily $C_{10}H_{11}Br_3$.

(β)-Phenyl-butylene $C_6H_5.CH:CMe_2$. (185°). Formed by heating benzoic aldehyde with sodium isobutyrate and isobutyric anhydride for 8 hours with inverted condenser (Perkin, *C. J.* 35, 138), and by distilling β-oxy-phenyl-valeric acid (Fittig a. Jayne, *A.* 216, 113). Oil. Forms an oily dibromide converted by alcoholic potash into $C_{10}H_{11}Br$, which forms crystalline $C_{10}H_{11}Br_3$ [63·5°]. Yields benzoic and acetic acids on oxidation. Nitrous acid forms $C_{10}H_{12}N_2O_3$ [112°] (Angeli, *B.* 25, 1962).

DI-PHENYL-BUTYLENE $C_{16}H_{16}$ *i.e.* $C_6H_5.CH:CH.CH_2.CH_2.C_6H_5$. [39°]. Formed by reduction of the nitrile of α-phenyl-β-styryl-acrylic acid (Freund a. Immerwahr, *B.* 23, 2858). Crystals, v. sol. alcohol. Yields a dibromide [83°].

DI-PHENYL-BUTYLENE-DIAMINE $C_4H_8(NHPh)_2$. Formed from isobutylene dibromide and aniline (Colson, *C. R.* 105, 1014; *Bl.* [2] 48, 800). Oil. Yields a nitrosamine [90°].—$B''H_2Cl_2$ [98°]. S. 10 at 15°.—$B''H_2Br_2$ [122°]. S. 10 at 15°; 20 at 100°.

DI-PHENYL-ISOBUTYL-GLYOXALINE [illegible] *i.e.* $\begin{matrix}CPh.NH\\CPh.N\end{matrix}\!\!>C.CH_2Pr$. [223°]. Formed from benzil, isovaleric aldehyde, and NH_3Aq (Japp a. Wynne, *C. J.* 49, 468).—$B'H_2PtCl_6$: crystalline.

PHENYL-ISOBUTYL-HYDRAZINE $C_4H_9NPh.NH_2$. (240°-245°). Formed from isobutyl bromide and sodium phenyl-hydrazine (Michaelis a. Philips, *B.* 20, 2485; *A.* 252, 282; 270, 122). Liquid, which reduces hot Fehling's solution. Converted by thionyl-aniline into oily $C_4H_9NPh.N{:}SO$—$B'H_2SO_4$: plates.

Acetyl derivative $C_4H_9NPh.NHAc$. [114°].

PHENYL BUTYL KETONE $C_6H_5.CO.CH_2Pr$. Mol. w. 162. (237°) at 720 mm. Got by boiling propyl-benzoyl-acetic ether with alcoholic potash (Perkin a. Calman, *C. J.* 49, 162). Oil.

Phenyl isobutyl ketone $C_6H_5.CO.CH_2Pr$. (228°) at 720 mm. S.G. $^{17·5}$ ·993. Formed from isopropyl-benzoyl-acetic ether (P. a. C.) and also by distilling a mixture of calcium benzoate and calcium isovalerate (Popoff, *A.* 162, 153). Liquid. Does not combine with $NaHSO_3$. Yields benzoic, isobutyric, and acetic acids on oxidation.

PHENYL BUTYL KETONE CARBOXYLIC ACID $C_6H_5.CO.CH_2.CHEt.CO_2H$. *Ethyl-benzoyl-propionic acid.* [83°]. Formed by heating the dicarboxylic acid. Small needles.—CaA'_2 aq.

Ethyl ether EtA'. Oil.

Phenyl butyl ketone carboxylic ether $C_6H_5.CO.CHPr.CO_2Et$. *Propyl-benzoyl-acetic acid* (251° at 300 mm.). Formed from benzoyl-acetic ether, NaOEt, and PrI at 100° (Perkin a. Calman, *C. J.* 49, 160). Liquid.

Phenyl isobutyl ketone carboxylic ether $C_6H_5.CO.CHPr.CO_2Et$. (237° at 225 mm.). Formed in like manner, using isopropyl iodide.

Phenyl butyl ketone dicarboxylic acid $C_6H_5.CO.CH_2.CEt(CO_2H)_2$. *Benzoyl-ethyl-isosuccinic ether.* Got by saponifying its ether, which is formed from sodium-malonic ether and ω-bromo-acetophenone (Dittrich a. Paal, *B.* 21, 3453). Crystalline mass.—$(NH_4)_2A''$: amorphous.—K_2A'': pearly plates, v. sol. water.—CaA'' aq.—Ag_2A'': plates. *Hydrazine salt.* [103°].

Phenyl hydrazide $C_{25}H_{26}N_4O_3$. [132°].

PHENYL BUTYL METHYLENE DIKETONE $C_6H_5.CO.CH_2.CO.CH_2Pr$. *Valeryl-acetophenone.* (184° at 30 mm.). Oil. Got from acetophenone, isovaleric ether, and NaOEt (Stylos, *B.* 20, 2181).

PHENYL-BUTYL METHYL KETONE CARBOXYLIC ETHER $CH_3.CO.CEt(CH_2Ph).CO_2Et$. (c. 297°). Formed from sodium benzyl-acetoacetate and EtI (Conrad, *B.* 11, 1057).

PHENYL BUTYL OXIDE *v. Butyl derivative* of PHENOL.

PHENYL-ISOBUTYLPHENYL-THIO-UREA $C_6H_5NH.CS.C_6H_4.CH_2Pr$. [152°]. Formed from $C_6H_4(NH_2).CH_2Pr$ and phenyl-thiocarbimide (Mainzer, *B.* 16, 2023). Plates, sol. alcohol.

DI-PHENYL-ISOBUTYL-QUINOXALINE $C_6H_3(CH_2Pr)\!<\!\begin{matrix}N{:}CPh\\N{:}CPh\end{matrix}$ [144°]. Formed from benzil and isobutylphenylene-diamine (Gelzer, *B.* 20, 3257). Needles, v. sol. alcohol.—B'_2HCl.

PHENYL-BUTYL-THIO-ALLOPHANIC ACID $NHPh.CS.N(C_4H_9).CN$. [139°]. Formed from sodium cyanamide, phenyl thiocarbimide, and isobutyl iodide (Hecht, *B.* 25, 822). Slender needles, v. sl. sol. hot water.

DI-PHENYL-ISOBUTYL-THIO-SEMI-CARBAZIDE $NHPh.CS.NH.NPh(CH_2Pr)$. [140°]. Formed from phenyl-isobutyl-hydrazine and phenyl-thiocarbimide (Michaelis a. Philips, *A.* 252, 284). White crystals.

PHENYL-ISOBUTYL-THIO-UREA $NHPh.CS.NHC_4H_9$ [82°]. Formed from phenyl-thiocarbimide and isobutylamine (Hecht, *B.* 25, 815). Needles, m. sol. hot water.

PHENYL-BUTYL-THIOHYDANTOÏN $CS\!<\!\begin{matrix}NPh.CO\\NH.CH(C_4H_9)\end{matrix}$. [179° uncor.]. Formed by fusing phenyl thiocarbimide with leucine (Aschan, *B.* 17, 426). Minute colourless prisms.

PHENYL-BUTYRIC ACID $C_{10}H_{12}O_2$ *i.e.* $CH_3CH_2.CHPhCO_2H$. [42°]. (272°). Formed by saponifying the nitrile which is made by the action of EtI and solid NaOH on benzyl cyanide (Neure, *A.* 250, 153). Crystalline mass.—CaA'_2 2aq; groups of needles.—AgA'.

Methyl ether MeA'. (228°).

Nitrile PhCHEt.CN. (245°).

γ-Phenyl-*n*-butyric acid $CH_2Ph.CH_2.CH_2.CO_2H$. [47·5°]. (290°). Formed from oxy-phenyl-butyric acid and HI (Burcker, *A. Ch.* [5] 26, 459) and from phenyl-isocrotonic acid by protracted treatment with sodium-amalgam (Jayne, *A.* 216, 107). Long flat plates (from water).—CaA'_2: amorphous mass.

Phenyl-isobutyric acid $CH_2Ph.CHMe.CO_2H$. *Benzyl-methyl-acetic acid.* [37°]. (272°). S. ·31 at 15°.

Formation.—1. By heating benzyl-methyl-malonic acid (Conrad, *B.* 13, 598).—2. By heating benzyl-methyl-acetoacetic ether with conc. KOHAq.—3. By reduction of the phenyl-crotonic acid obtained from benzoic aldehyde, sodium propionate, and propionic anhydride.—4. By reducing phenyl-angelic (methyl-cinnamic) acid with sodium-amalgam (von Miller, *B.* 23, 1888).

Properties.—Plates. Converted by H_2SO_4 at 150° into oxy-methyl-indonaphthene.

Salt.—AgA'. S. ·248 at 20°.

Ethyl ether EtA'. (287°). S.G. $\frac{22}{17}$ 1·05. Oil (Conrad a. Bischoff, *A.* 204, 177).

Benzyl ether C_7H_7A'. (320°-325°). S.G. $^{16·5}$ 1·046. A product of the action of sodium on benzyl propionate (Conrad a. Hodgkinson, *A.* 193, 312).

Amide $CH_2Ph.CHMe.CONH_2$. [109°]. Formed by heating the NH_4 salt (Edeleano, *B.* 20, 618). Needles, v. sol. alcohol and ether.

Di-phenyl-butyric acid $CH_2Ph.CMePh.CO_2H$. [126°]. Got from its nitrile, which is obtained from α-phenyl-propionitrile and benzyl chloride (Janssen, *A.* 250, 137). Needles, v. sol. ether and alcohol.—NaA'7aq: long thin needles.—CaA'_2.—BaA'_2.—CuA_2'. [78°].—AgA': white insoluble powder.

Nitrile $C_{16}H_{15}CN$. (337°). Oil.

Isomeride *v.* DI-BENZYL-ACETIC ACID.

References.—BROMO-, NITRO-, NITRO-AMIDO-, and OXY- PHENYL-BUTYRIC ACID.

PHENYL-ISOBUTYRIC ALDEHYDE $CH_3.CH(CH_2Ph).CHO$. (227°). Formed by distilling the corresponding lime salt with calcium formate (Miller a. Rohde, *B.* 23, 1080). Oil.

γ-PHENYL-BUTYRIC-*o*-CARBOXYLIC ACID $C_{11}H_{12}O_4$ *i.e.* $C_6H_4(CO_2H).CH_2.CH_2.CH_2.CO_2H$. [139°]. Formed by heating at 180°–190° the double-lactone of benzoyl-propionic-*o*-carboxylic acid  $C_6H_4\left\langle\begin{matrix}\text{——}\\CO\cdot O\end{matrix}\right\rangle C\left\langle\begin{matrix}CH_2\\O\cdot CO\end{matrix}\right\rangle CH_2$ with HI and P (Roser, *B.* 18, 3118). Small plates. V. sol. alcohol, sl. sol. cold water.—A″Ba: very soluble in water.

PHENYL-BUTYRO-LACTONE *v.* *Lactone* of OXYPHENYL-BUTYRIC ACID.

PHENYL-CACODYL *v.* vol. i. p. 320.

PHENYL-CAMPHORAMIC ACID *v.* CAMPHORIC ACID.

PHENYL-CAMPHYL-THIO-UREA *v.* CAMPHYL-THIO-UREA.

PHENYL CARBAMATE $NH_2.CO_2Ph$. [143°]. Formed by the action, in ethereal solution, of NH_3 on $ClCO_2Ph$ or of $NH_2.COCl$ on phenol (Kempf, *B.* 2, 740; Gattermann, *A.* 244, 43). Formed also, together with Et_2CO_3, by heating phenyl ethyl carbonate at 300° (Bender, *B.* 19, 2268). Needles (from water), sol. alcohol and ether. Decomposed by NaOHAq into NH_3, phenol, and Na_2CO_3. NH_3Aq at 150° forms phenol and urea.

PHENYL-CARBAMIC ACID $NHPh.CO_2H$. *Carbanilic acid.* The ethers of this acid are got by the action of aniline on the chloroformic ethers Cl.CO.OR, and also by the action of phenyl cyanate on alcohols. They are decomposed by potash into CO_2, aniline, and alcohols.

Acetyl derivative $NPhAc.CO_2H$. The Na salt is formed by passing CO_2 over sodium acetanilide in the cold (Seifert, *B.* 18, 1358). It is decomposed by water into acetanilide and $NaHCO_3$. By heating at 140° under pressure it is converted into $NPhH.CO.CH_2.CO_2Na$.

Methyl ether NHPh.CO.OMe. [47°] (Hentschel, *B.* 18, 978). Prisms. Converted by HNO_3 (S.G. 1·48) into $C_6H_3(NO_2)_2NH.CO_2Me$ [127°] and [6:4:2:1]$C_6H_2(NO_2)_3.NH.CO_2Me$ [192°] (Van Romburgh, *R. T. C.* 10, 135). H_2SO_4 forms $SO_3H.C_6H_4.NH.CO_2Me$ which is converted by bromine into $C_6H_3Br_2NH.CO_2Me$ [96·5°] (Hentschel, *J. pr.* [2] 34, 423). Distillation with lime at 260° gives aniline, methyl-aniline, di-methyl-aniline, and di-phenyl-urea (Nölting, *B.* 21, 3154).

Ethyl ether $NHPh.CO_2Et$. [52°]. (238°) (Wilm a. Wischin, *C. J.* 21, 192). Formed as above and also by boiling the product of the action of phenyl-urea on aceto-acetic ether with conc. HCl (Behrend, *A.* 233, 6) and by the action of sodium acetanilide on chloro-formic ether (Paal a. Otten, *B.* 23, 2590). Needles (from water). Not affected by boiling conc. HClAq, but decomposed by HClAq at 150° into CO_2, aniline, and EtCl. Boiling alcoholic KOH gives aniline and K_2CO_3. Yields a bromo-derivative [81°], a di-nitro- derivative [110°], and a tri-nitro- derivative [144°]. When distilled with NaOPh at 220° it gives phenol and di-phenyl-urea [235°] (Hentschel, *J. pr.* [2] 27, 498). — $NKPh.CO_2Et$. Formed by dissolving phenyl-carbamic ether in alcoholic potash. Hygroscopic needles, decomposed by water.

Chloro-ethyl ether $NHPh.CO_2.CH_2.CH_2Cl$. [51°]. Formed from aniline and $Cl.CO.OC_2H_4Cl$ (Nemirowsky, *J. pr.* [2] 31, 174; Otto, *J. pr.* [2] 44, 15). Needles, sl. sol. hot water. When boiled alone and afterwards with conc. KOH it yields $NPh\left\langle\begin{matrix}CO\\CH_2\end{matrix}\right\rangle CH_2$ [124°], which is converted by HClAq at 170° into chloro-ethyl-aniline.

Ethylene ether C_2H_4A''. [158°]. Formed from ethylene glycol and phenyl cyanate (Snape, *B.* 18, 2430; *C. J.* 47, 773). Prisms.

Propyl ether PrA′. [59°]. Slender needles, v. sol. alcohol (Römer, *B.* 6, 1101).

Isopropyl ether PrA′. [90°] (Gumpert, *J. pr.* [2] 31, 119; 32, 278); [43°] (Spica, *G.* 17, 165). Needles (from dilute alcohol).

Di-chloro-propyl ether (Otto, *J. pr.* [2] 44, 22) $CH_2Cl.CHCl.CH_2A'$. [74°]. Prisms.

Isobutyl ether C_4H_9A'. [80°]. (216°). Needles, v. sol. alcohol (Mylius, *B.* 5, 972).

Heptenyl ether $C_7H_{13}A'$. [85°]. Formed by the action of phenyl cyanate on the heptenyl alcohol got by reducing suberone (Markownikoff, *C. R.* 110, 466). Prisms (from alcohol).

Glyceryl ether v. GLYCERYL-TRI-PHENYL-TRI-CARBAMATE.

Phenyl ether $NHPh.CO_2Ph$. [126°]. Formed from phenyl cyanate and phenol (Gumpert; *cf.* Hofmann, *B.* 4, 249). Needles (from benzene). With NH_3Aq it forms phenyl-urea.

Phenylene ethers. The *o* [165°], *m* [164°], and *p* [207°] compounds are got by heating pyrocatechin, resorcin, and hydroquinone respectively with phenyl cyanate (Snape, *B.* 18, 2428).

Phenylphenyl ether $C_6H_5.C_6H_4A'$. [110°]. Formed from *p*-amido-diphenyl and $ClCO_2Et$ (Zimmermann, *B.* 13, 1965).

(α)-*Naphthyl ether* $C_{10}H_7A'$. [178·5°]. Slender needles (Leuchart a. Schmidt, *B.* 18, 2340; Snape, *C. J.* 47, 776). Decomposed by heat into (α)-naphthol and phenyl cyanate.

(β)-*Naphthyl ether* $C_{10}H_7A'$. [230°]. (L. a. S.); [155°] (S.). Thick prisms. The tetrahydride $C_{10}H_{11}O.CONPhH$ [98·5°] is formed from (β)-naphthol *ac*-tetrahydride and phenyl cyanate.

Di-phenyl-carbamic acid.

Chloride $NPh_2.COCl$. [85°]. Formed from $COCl_2$ and diphenylamine in $CHCl_3$ (Michler, *B.* 9, 396). White scales (from alcohol).

Ethyl ether $NPh_2.CO_2Et$. [72°]. (above 360°). Formed by heating diphenylamine with $ClCO_2Et$ (Merz a. Werth, *B.* 6, 1511; Hager, *B.* 18, 2573). Large prisms (from benzene).

Phenyl ether PhA′. [104°]. Formed from the chloride and KOPh (Lellmann a. Bonhöffer, *B.* 20, 2122). The compound $C_6H_4(NO_2)A'$ [114°], made in like manner from *o*-nitrophenol, may be reduced to $C_6H_4(NH_2)A'$ [191°]. The *m*- and *p*- nitro-phenyl ethers [90°] and [116°] yield *m*- and *p*- amido-phenyl ethers [133°] and [146°] (Lellmann a. Benz, *B.* 24, 2111).

p-Tolyl-ether C_7H_7A'. [81°]. (L. a. B.).

References.—AMIDO-, BROMO-, DI-BROMO-NITRO-, NITRO-, NITRO-AMIDO-, NITRO-OXY-, OXY-, OXY-AMIDO-, and NITRO- PHENYL-CARBAMIC ACID and ETHER.

PHENYL-CARBAMINE C_6H_5NC. Mol. w. 103. (167°). S.V. 121·6 (Lossen, *A.* 254, 73). Formed by distilling aniline with chloroform and alcoholic potash (Hofmann, *A.* 144, 117). Stinking liquid, quickly decomposed by acids into aniline and formic acid. Changes into the isomeric benzonitrile by heating at 210° (Weith, *B.* 6, 210). Yields phenyl-thiocarbimide on heating with sulphur. Mixed with propionitrile and ether, it yields, by successive treatment with sodium and water, the compound $CPh(NH).CHMe.CN$ [97°] (Von Meyer, *J. pr.* [2] 39, 189).

Chloride $NPh.CCl_2$ (212°). Formed from phenyl-thiocarbimide and Cl (Sell a. Zierold, *B.* 7, 1228). Pungent liquid, with nasty smell, yielding *s*-di-phenyl-urea when heated with water at 100°.

PHENYL-CARBAZIC ACID. The crystalline salt $N_2H_2Ph.CO.ON_2H_4Ph$ is formed by the action of CO_2 on phenyl-hydrazine and water. It is deliquescent, and sl. sol. water and ether (Fischer, *A.* 190, 124).

Methyl ether $NHPh.NH.CO_2Me$. [117°]. Short prisms (Heller, *A.* 263, 281).

Ethyl ether $NHPh.NH.CO_2Et$. [87°] (F.); [82°] (N.). Formed from phenyl-hydrazine and $ClCO_2Et$ (E. Fischer, *B.* 22, 1936), or $AcC(CO_2Et)_3$ (Nef, *A.* 266, 107). Needles. Ac_2O forms $C_6H_5.N_2HAc.CO_2Et$ [103°] (H.).

PHENYL-*semi*-CARBAZIDE $C_7H_9N_3O$ *i.e.* $NHPh.NH.CO.NH_2$. [172°]. Formed from potassium cyanate and phenyl-hydrazine hydrochloride (E. Fischer, *A.* 190, 113; Freund, *B.* 21, 2463). Formed also by heating phenyl-hydrazine hydrochloride (1 mol.) with urea (2 mols.) at 160° for 4 hours (Pinner, *B.* 20, 2358; 21, 2329) and by heating di-phenyl-carbazide with urea (Skinner a. Ruhemann, *C. J.* 53, 550; *B.* 20, 3378). Prisms, v. sol. hot water. Yields di-oxy-phenyl-triazole [263°] on heating with urea. By heating at 160° it is converted into di-phenyl-urazine $C_{14}H_{12}N_4O_2$ [264°] and other products. $COCl_2$ forms $C_8H_7N_3O_2$ [167°].

Benzoyl derivative $NPhBz.NH.CO.NH_2$. [203°]. Formed from benzoyl-phenyl-hydrazine cyanate (Michaelis a. Schmidt, *A.* 252, 317).

Di-phenyl-*semi*-carbazide $C_6H_5NH.CO.N_2HPh$. [173°]. Formed from phenyl-hydrazine by combination with phenyl cyanate; and also by heating phenyl-hydrazine with phenyl-urea (Kühn, *B.* 17, 2884; Skinner, *C. J.* 53, 552). Needles or plates (from alcohol or benzene), sl. sol. water. $COCl_2$ in benzene forms $C_{14}H_{11}N_3O_2$ [173°] (Freund, *B.* 21, 2465).

Di-phenyl-carbazide $CO(N_2H_2Ph)_2$. [151°] (S. a. K.); [164°] (E. Fischer, *B.* 22, 1930). Formed by heating phenyl-hydrazine (2 mols.) with carbamic ether (1 mol.) (Skinner a. Ruhemann, *C. J.* 53, 550; *B.* 20, 3372). Formed also from phenyl-hydrazine and $COCl_2$ (Heller, *A.* 263, 277). Crystalline. Forms with $HgCl_2$ a crystalline compound $B'HgCl_2$ not melted at 136°. Alcoholic potash forms a red solution containing *di-phenyl-carbazone* $N_2H_2Ph.CO.N:NPh$ crystallising in orange needles [157°]. Benzene and $CSCl_2$ form  $CS\left\langle\begin{matrix}NPh.N\\O\text{———}\end{matrix}\right\rangle C.N:NPh$ [176°] (Freund a. Kuh, *B.* 23, 2833).

PHENYL-CARBIMIDE *v. Phenyl isocyanate*, vol. ii. p. 315.

DI-PHENYL-DI-CARBIMIDO-TETRA-*p*-AMIDO-TETRA-TOLYL-DI-*o*-SULPHIDE

$PhN:C\left\langle\begin{matrix}NH.C_7H_6.S.C_7H_6.NH\\NH.C_7H_6.S.C_7H_6.NH\end{matrix}\right\rangle C:NPh$. *Di-thio-p-tolyl-di-phenyl-di-guanidine.* [c. 119°]. Formed by heating di-thiocarbonyl-tetra-amido-tetra-tolyl-di-sulphide with aniline and HgO (Truhlar, *B.* 20, 674). Amorphous; v. sol. alcohol.

DI-PHENYL-CARBINOL $C_{13}H_{12}O$ *i.e.* $Ph_2CH(OH)$. *Benzhydrol.* Mol. w. 184. [68°]. (298°). S. ·05 at 20°. *Initial velocity of etherification* 22 (Menschutkin, *J. R.* 1882, 162). Formed by reducing benzophenone with sodium-amalgam (Linnemann, *A.* 133, 6; Beckmann, *B.* 22, 915); or by heating benzophenone with zinc and alcoholic KOH (Zagumenny, *A.* 184, 174). Slender silky needles, v. e. sol. alcohol and ether. Converted into benzophenone by oxidation with chromic acid. Bromine forms a dibromo-benzhydrol [163°]. Zn and HOAc form benzpinacone. Zn and HCl in acetic acid solution reduce it to tetra-phenyl-ethane. Distillation partly resolves benzhydrol into water and benzhydrolic ether. P_2S_5 forms $C_{26}H_{22}(SH)_2$ [151°] and oily $Ph_2CH(SH)$ (Engler, *B.* 11, 922).

Ethyl derivative $C_{13}H_{11}OEt$. (288°). S.G. ^{20} 1·03. From benzhydrol, alcohol, and H_2SO_4, or from Ph_2CHBr and alcoholic KOH (Friedel a. Balsohn, *Bl.* [2] 33, 339). Liquid.

Isoamyl derivative $C_{13}H_{11}OC_5H_{11}$. (310°).

Chloride Ph_2CHCl. [14°]. From benzhydrol and HCl (Engler a. Bethge, *B.* 7, 1128).

Bromide Ph_2CHBr. [45°]. From di-phenyl-methane and bromine at 150° (F. a. B.). Water at 150° decomposes it into benzhydrol and benzhydrolic ether. Conc. NH_3Aq forms mono- and di-benzhydryl-amine (Friedel a. Balsohn, *Bl.* [2] 33, 587).

Acetyl derivative $Ph_2CH.OAc$. [42°]. (302°). S.G. ^{22} 1·49. Prisms, v. sol. alcohol, acetic acid, and ether (Vincent, *Bl.* [2] 35, 804).

Benzoyl derivative $Ph_2CH.OBz$. [89°]. Non-volatile. Trimetric, $a:b:c = 1 : ·477 : ·668$.

Succinyl derivative $(Ph_2CH.O)_2:C_2O_2:C_2H_4$. [142°]. Gives, on distillation, succinic acid and benzhydrolene $C_{13}H_{10}$ [210°].

Anhydride $C_{26}H_{20}O$ *i.e.*  $\underset{\diagdown\;\diagup\atop O}{Ph_2C{-}CPh_2}$(?) [111°]. (315°) at 745 mm. From benzhydrol by long boiling with water or by treatment with PCl_3, BzCl, or diluted H_2SO_4. Monoclinic crystals (from benzene). Reduced by zinc and HCl in HOAc to tetra-phenyl-methane (Zagumenny, *J. R.* 12, 431). Zincke a. Thörner (*B.* 11, 1398) obtained this anhydride by heating benzpinacone, $C_{26}H_{22}O_2$, and consequently assume the formula $C_{26}H_{20}O$.

References.—DI-AMIDO-, DI-BROMO-, and OXY-DI-PHENYL-CARBINOL.

Tri-phenyl-carbinol $C_{19}H_{16}O$ *i.e.* $CPh_3.OH$. Mol. w. 260. [159°]. (above 360°).

Formation.—1. By boiling tri-phenyl-methane with chromic acid mixture (Hemilian, *B.* 7, 1203).—2. From CPh_3Br and water.—3. By the action of water on CPh_3Cl got from $AlCl_3$, benzene, and CCl_4, or $CCl_3.COCl$ (Friede a. Crafts, *A. Ch.* [6] 1, 499; Hentschel, *J. pr.* [2] 36, 311).—4. By heating its dicarboxylic acid with baryta (Hemilian, *B.* 19, 3073).

Properties.—Six-sided plates, v. sol. alcohol.

Acetyl derivative $CPh_3.OAc$. [99°]. Prisms (Allen a. Kölliker, *A.* 227, 116).

Methyl ether $CPh_3.OMe$. [82°]. Laminæ.

Ethyl ether $CPh_3.OEt$. [79°] (F. a. C.); [83°] (A. a. K.).

Chloride v. CHLORO-TRI-PHENYL-METHANE.

DI-PHENYL-CARBINOL CARBOXYLIC ACID v. OXY-BENZYL-BENZOIC ACID.

Di-phenyl-carbinol dicarboxylic acid $CH(OH)(C_6H_4.CO_2H)_2$. Formed by heating benzil di-*o*-carboxylic (diphthalylic) acid with KOHAq (50 p.c.) at 180° for 5 minutes (Graebe a. Juillard, *A.* 242, 238). The acid splits up at the moment of liberation into water and anhydride.—BaA''aq.

Anhydride $C_{15}H_{10}O_4$. [203°]. S. ·022 at 23°. Formed as above, and also by reducing benzophenone di-*o*-carboxylic acid. Monoclinic crystals (from alcohol). On heating, it yields a white sublimate [172°] reconverted by treatment with NaOHAq and HCl into the original anhydride. Phenyl-hydrazine gives $C_{21}H_{16}N_2O_3$. H_2SO_4 and HNO_3 give $C_{15}H_8(NO_2)_2O_4$ [c. 275°], which forms EtA′ [148°].—$Ba(C_{15}H_9O_5)_2$ 2½aq.—CuA'_2 3aq.—AgA′.—$C_{15}H_9MeA'$. [155°].—EtA′. [100°].—$C_{15}H_9O_3(NH_2)$. [160°]. Needles.

Isomeride v. OXY-BENZYL-ISOPHTHALIC ACID.

Di-phenyl-carbinol tri-carboxylic acid $C(OH)(CO_2H)(C_6H_4.CO_2H)_2$.

Anhydride $C_{16}H_{10}O_6$. [170°]. Formed by heating benzil di-*o*-carboxylic acid with NaOHAq (4 p.c.) at 112° for 3 minutes (G. a. J.). Minute crystals, sl. sol. cold water. Gives off CO_2 on heating, yielding the anhydride of di-phenyl-carbinol dicarboxylic acid.

Ethers of the anhydride Me_2A''. [148°].—Et_2A''. [108°]. Prisms, v. sol. alcohol.

Tri-phenyl-carbinol *o*-carboxylic acid *$CPh_2(OH).C_6H_4.CO_2H$. The Na salt is formed by heating di-phenyl-phthalide with NaOHAq, but the acid splits up on liberation into water and its anhydride, di-phenyl-phthalide (Baeyer, *A.* 202, 50).

Tri-phenyl-carbinol *m*-carboxylic acid. [162°]. Formed by oxidation of di-phenyl-*m*-tolyl-methane with CrO_3 and HOAc (Hemilian, *B.* 16, 2369). Trimetric plates.

Tri-phenyl-carbinol *p*-carboxylic acid (?). [187°]. Formed by oxidation of $CHPh_2.C_6H_4.CHO$ (Oppenheim, *B.* 19, 2028) or of di-phenyl-tolyl-methane (Hemilian, *B.* 7, 1210). Needles.—$BaA'_2$7aq. Needles, v. sl. sol. cold water.

Tri-phenyl-carbinol dicarboxylic acid. *Anhydride*

$CPh_2{<}{\begin{matrix}C_6H_3(CO_2H)\\O\text{———}CO\end{matrix}}{>}$.

Di-phenyl-phthalide carboxylic acid. [246°]. Formed by oxidation of di-phenyl-*y*-xylyl-methane, di-phenyl-tolyl-methane *o*-carboxylic acid, di-phenyl-tolyl-carbinol *m*-carboxylic acid, or di-phenyl-methyl-phthalide (Hemilian, *B.* 16, 2372). Crystals, v. sol. alcohol and HOAc. Yields benzophenone and terephthalic acid on fusion with potash. Zinc-dust and NaOHAq reduce it to tri-phenyl-methane dicarboxylic acid.

Tri-phenyl-carbinol dicarboxylic acid $C_{21}H_{16}O_5$ *i.e.* $CPh_2(OH).C_6H_3(CO_2H)_2$ [1:3:4]. [180°]. Formed by oxidation of di-phenyl-xylyl-methane with $K_2Cr_2O_7$ and H_2SO_4Aq (Hemilian, *B.* 19, 3072). Needles (from water), v. e. sol. alcohol. On fusion it yields an amorphous anhydride $C_{21}H_{14}O_4$. On fusion with $Ba(OH)_2$ it forms tri-phenyl-carbinol.—Ag_2A'' : pp.

Tri-phenyl-carbinol dicarboxylic acid $CPh_2(OH).C_6H_3(CO_2H)_2$ [1:2:4]. *Anhydride* $C_{21}H_{14}O_4$. *Di-phenyl-phthalide carboxylic acid.* [228°]. Formed by oxidation of the corresponding di-phenyl-xylyl-methane (H.). Tables (containing EtOH).—CaA'_2 3aq.—AgA′: needles.

DI-PHENYL-CARBINYLAMINE $C_{13}H_{13}N$ *i.e.* $CHPh_2.NH_2$. *Benzhydrylamine. Exo-amido-di-phenyl-methane.* (289°). Formed, together with tetra-phenyl-di-carbinyl-amine, by leaving benzhydryl bromide, $CHPh_2Br$, with conc. NH_3Aq for 48 hours (Friedel a. Balsohn, *Bl.* [2] 33, 587). Got also by reducing benzophenone-oxim in alcoholic solution by sodium-amalgam and acetic acid (Goldschmidt, *B.* 19, 3233).

Properties.—Alkaline liquid, absorbing CO_2 from the air.

Salts.—B′HCl: [270°]; long needles, sl. sol. cold water.—$B'_2H_2PtCl_6$ 2aq : lancet-like needles (L. a. B.); $B'H_2PtCl_6$aq (G.).—*$B'_2H_2CO_3$. [91°].

Formyl derivative $Ph_2CH.NH.CHO$. [132°]. (360°). Formed, almost quantitatively, by heating benzophenone with ammonium formate at 200°–220° (Leuchart a. Bach, *B.* 19, 2129).

Urea $Ph_2CH.NH.CO.NH_2$. [143°] (L. a. B.).

Tetra-phenyl-di-carbinyl-amine $(Ph_2CH)_2NH$. [136°]. Prepared as above, crystallises from alcohol in slender needles, not affected by MeI or AcCl at 100° (F. a. B.).

Tri-phenyl-carbinyl-amine $CPh_3.NH_2$. [103°]. Formed by passing dry NH_3 through a solution of CPh_3Br in benzene (Hemilian a. Silberstein, *Bl.* [2] 43, 118; *B.* 17, 741; *cf.* Nauen, *B.* 17, 442). Needles, sl. sol. cold alcohol. Yields B′HCl, $B'_2H_2PtCl_6$ 7½aq, CPh_3NHMe [73°], CPh_3NMe_2 [97°], CPh_3NHPh [145°], CPh_3NHCH_2Ph [110°], and the acetyl derivative $CPh_3.NHAc$ [208°]. Forms a crystalline oxalate [253°] (Elbs, *B.* 17, 701), and the compounds $C_{19}H_{17}NBr_2$, $B'I_2$, and B'_2I_7.

PHENYL-CARBINYL CHLORIDE v. CHLORO-TRI-PHENYL-METHANE.

TRI-PHENYL-CARBINYL-MALONIC ETHER $CPh_3.CH(CO_2Et)_2$. [133·5°]. Got from sodium malonic ether and CPh_3Br (Henderson, *B.* 20, 1014). Needles (from alcohol).

TRI-PHENYL-CARBINYL SULPHOCYANIDE $CPh_3.NCS$. [137°]. Formed from CPh_3Br and ammonium sulphocyanide (Elbs, *B.* 17, 700).

TRI-PHENYL-CARBINYL-TOLUIDINE $CPh_3.NHC_7H_7$. The *o* [142°] and *p* [177°] compounds are formed from CPh_3Br and *o* and *p* toluidine respectively (Elbs, *B.* 17, 706). The *p*-compound yields a crystalline nitrosamine [145°–148°].

PHENYL-CARBIZINE. *Formyl derivative*

$C_6H_4N{<}{\begin{matrix}N.CHO\\CO\end{matrix}}$. [72°]. (256°). Formed by the action of $COCl_2$ in benzene on the phenyl-hydrazide of formic aldehyde (Freund, *B.* 21, 1240, 2458). Needles (from CS_2), v. sol. alcohol and ether. Decomposed by boiling Na_2CO_3Aq into CO_2, and the phenyl-hydrazide of formic aldehyde.

Acetyl derivative

$CO{<}{\begin{matrix}NPh\\NAc\end{matrix}}$. [94°]. (280°). Formed in like manner from acetic aldehyde. Monoclinic prisms; $a:b:c = 1·210:1:1·557$; $\beta = 73°$ 23′.

Propionyl derivative. [63°]. Needles.

Benzoyl derivative

$CO{<}{\begin{matrix}NBz\\NPh\end{matrix}}$. [114°]. Needles (from alcohol) or plates (from HOAc).

PHENYL CARBONATES.

Phenyl-carbonic acid *$C_6H_5O.CO_2H$.

Sodium salt $PhO.CO_2Na$. Prepared by treating dry sodium phenylate in the cold for a month with CO_2 until it has taken up the calculated quantity of the gas. The product is a very hygroscopic powder.

Reactions.—1. With *water* it gives off half its CO_2 in gaseous form: $2PhO.CO_2Na + H_2O = PhONa + PhOH + NaHCO_3 + CO_2$.—2. At 120° it splits up into CO_2 and PhONa.—3. Heated rapidly to 180°-200° it gives off smaller quantities of CO_2 together with phenol, the residue being sodium salicylate.—4. In a sealed tube at 120°-130° for several hours it changes completely to sodium salicylate: $C_6H_5O.CO_2Na = C_6H_4(OH)CO_2Na$ (R. Schmilt, *J. pr.* [2] 31, 408).

Di-phenyl carbonate $C_{13}H_{10}O_3$ *i.e.* $CO(OPh)_2$. [78°] (Kempf, *J. pr.* [2] 1, 404; Hentschel, *J. pr.* [2] 27, 41; 36, 315); [88°] (Richter, *J. pr.* [2] 27, 41). (303°). Formed by passing $COCl_2$ into an aqueous solution of NaOPh, or into phenol containing $AlCl_3$. Formed also from $ClCO_2CCl_3$, phenol, and $AlCl_3$. Needles (from alcohol). Alcoholic potash forms phenol and K_2CO_3. NaSEt gives NaSPh and $(EtS)_2CO$ (Seiffert, *J. pr.* [2] 31, 464).

References.—DI-BROMO- and NITRO- PHENYL CARBONATE.

DIPHENYL *o*-CARBOXYLIC ACID $C_{13}H_{10}O_2$ *i.e.* $C_6H_5.C_6H_4.CO_2H$ [1:2]. *Phenyl-benzoic acid.* Mol. w. 198. [111°]. Formed by potash-fusion from diphenylene ketone (Fittig a. Ostermaier, *B.* 5, 933; *A.* 166, 374; Schmitz, *A.* 193, 115). Formed also, together with diphenylene ketone oxide, by distilling sodium salicylate with triphenyl phosphate (R. Richter, *J. pr.* [2] 28, 305). Small needles (from hot alcohol), m. sol. hot water.—KA′aq.—BaA′$_2$aq.—CaA′$_2$2aq.—AgA′.

Ethyl ether EtA′. (300°-305°).

Tetrahydride $C_6H_5.C_6H_{10}.CO_2H$. *Phenyl-hexamethylene carboxylic acid.* [105°]. Formed by heating the corresponding dicarboxylic acid, and by the hydrolysis of phenylhexamethylenyl methyl ketone carboxylic ether (Kipping a. W. H. Perkin, jun., *C. J.* 57, 319). Rosettes of crystals (from ligroïn).—AgA′: amorphous pp.

Diphenyl *m*-carboxylic acid $C_6H_5.C_6H_4.CO_2H$. [161°]. Formed by oxidation by chromic acid and HOAc from [1:3] $C_6H_4Ph_2$, from C_6H_4PhMe, and from $C_6H_4Ph.CH_2Br$ (Schmidt a. Schultz, *A.* 203, 132; Adam, *A. Ch.* [6] 15, 243). It is also a product of the fusion of benzoic acid with potash (Barth a. Schreder, *M.* 3, 808). Leaflets (from alcohol), sl. sol. water. Yields isophthalic acid on oxidation.—NaA′$_2$ 2aq.—CaA′$_2$ 3aq.—BaA′$_2$ 3½aq: needles.—BaA′$_2$ 4½aq.

Ethyl ether EtA′. (above 360°). Oil.

Diphenyl *p*-carboxylic acid $C_6H_5.C_6H_4.CO_2H$. [219°]. Formed by saponification of its nitrile, which is got by heating potassium diphenyl sulphonate with KCy in a current of dry CO_2 (Doebner, *A.* 172, 109). Formed also by oxidation of [1:4] $C_6H_4Ph_2$ or [1:4] C_6H_4PhMe (Schultz, *A.* 174, 213; Carnelley, *C. J.* 37, 713). It is also a product of the fusion of benzoic acid with potash. Tufts of needles (from alcohol), v. sl. sol. hot water. May be sublimed. Yields terephthalic acid on oxidation.—BaA′$_2$.—CaA′$_2$.

Ethyl ether EtA′. [46°]. Prisms.

Nitrile $C_{12}H_9.CN$. [85°]. Crystals.

Anilide $C_{12}H_9.CO.NHPh$. [224°]. Got by heating $C_{12}H_9.C(NOH).C_6H_5$ with HOAc, Ac_2O, and dry HCl at 100° (Koller, *M.* 12, 503).

Diphenyl di-*o*-carboxylic acid $C_{14}H_{10}O_4$ *i.e.* [2:1]$CO_2H.C_6H_4.C_6H_4.CO_2H$[1:2]. *Diphenic acid.* Mol. w. 242. [228°]. Formed by the oxidation of phenanthraquinone or phenanthrene (Fittig a. Ostermayer, *A.* 166, 361; Schmitz, *A.* 193, 116). It is also produced when phenanthraquinone is boiled with conc. alcoholic potash (Anschütz a. Schultz, *A.* 196, 50; 203, 97). Plates or prisms, m. sol. hot water. May be sublimed. By exhaustive chlorination with $SbCl_5$ it yields perchloro-diphenyl, together with a small quantity of perchloro-benzene (Merz a. Weith, *B.* 16, 2872). Distillation over with red-hot CaO yields diphenylene ketone; distillation with $Ca(OH)_2$ gives diphenyl.

Salts.—BaA″4aq: v. sol. water.—CaA″ 2½aq.—MgA″4aq.—Ag$_2$A″: bulky white pp.

Methyl ethers Me$_2$A″. [73·5°].—MeHA″. [110°]. Plates, m. sol. water. Got by boiling the anhydride with MeOH.

Ethyl ethers Et$_2$A″. [42°]. Crystals, insol. Aq (Hummel, *A.* 193, 128).—EtHA″. [88°].

Anhydride  $\left.\begin{matrix}C_6H_4.CO\\C_6H_4.CO\end{matrix}\right>O$. [213°].
Formed by boiling the acid with AcCl or Ac_2O (Anschütz, *B.* 10, 1884; 13, 1302: Graebe, *B.* 20, 848; *A.* 247, 261). Needles, insol. water, sol. alcohol. Decomposed by heat into CO_2 and diphenylene ketone. H_2SO_4 at 100° forms diphenylene ketone carboxylic acid [217°]. Phenyl-hydrazine forms the crystalline compound $CO_2H.C_6H_4.C_6H_4.CO.N_2H_2Ph$ [174° cor.] which at 250° yields  $\left.\begin{matrix}C_6H_4.CO\\C_6H_4.CO\end{matrix}\right>N.NHPh$ [150°]. Benzene and $AlCl_3$ form an acid [148°].

Chloride $C_{12}H_8(COCl)_2$. [98°]. Formed from the anhydride and PCl_5. Yields di-oxy-phenanthrene on reduction.

Amide $C_{12}H_8(CO.NH_2)_2$. [212°]. Formed by warming the imide with conc. NH_3Aq.

Amic acid $C_{12}H_8(CO_2H)(CONH_2)$. [193°]. Got by boiling the anhydride with NH_3Aq. Plates (from alcohol). Converted by heat into the imide.

Imide  $\left.\begin{matrix}C_6H_4.CO\\C_6H_4.CO\end{matrix}\right>NH$. [220°]. Formed as above, and also by the action of conc. HClAq on the mono-oxim of phenanthraquinone (Wegerhoff, *A.* 252, 18). Needles (from alcohol), sl. sol. hot water. Yields an acetyl derivative [92°], and forms $C_{14}H_8O_2(NNa)$, $C_{14}H_8O_2(NAg)$, and $C_{14}H_8O_2(NMe)$.

Diphenyl *om*-dicarboxylic acid [2:1] $CO_2H.C_6H_4.C_6H_4.CO_2H$ [1:3]. *Isodiphenic acid.* [216°]. Formed by fusing diphenylene ketone carboxylic acid with potash (Fittig a. Lieppmann, *B.* 12, 163; *A.* 193, 155; 200, 9). Needles (from hot water). Yields diphenylene ketone on heating with lime. Gives isophthalic acid on oxidation with CrO_3.—BaA″ 6aq. Crystalline.—CaA″ 2aq.—Ag$_2$A″: pp., sl. sol. hot water.

Methyl ether Me$_2$A″. [69·5°].

Ethyl ether Et$_2$A″. Thick oil.

Diphenyl *op*-di-carboxylic acid [2:1] $CO_2H.C_6H_4.C_6H_4.CO_2H$ [1:4]. [252°]. Formed by saponification of its nitrile [158°] which is got by Sandmeyer's reaction from *op*-di-amido-diphenyl (Reuland, *B.* 22, 3018).

Diphenyl di-*m*-carboxylic acid. [above 340°]. Formed by the action of nitrous acid on di-*p*-amido-diphenyl dicarboxylic acid (Griess, *B.* 21, 982). Small needles, almost insol. cold water.—BaA″ 3½aq: crystalline aggregates.

Diphenyl di-*p*-carboxylic acid [4:1] $CO_2H.C_6H_4.C_6H_4.CO_2H$ [1:4]. Formed by saponification of its nitrile, and also by oxidation of *p*-ditolyl (Doebner, *B.* 9, 129, 272; *A.* 172, 109). Amorphous powder, nearly insol. most solvents.—CaA″: insoluble pp.—BaA″.—Ag_2A'': white pp.

Ethyl ether Et_2A''. [112°]. Prisms.

Nitrile $C_{12}H_8(CN)_2$. [234°]. Formed by heating potassium diphenyl disulphonate with KCy. Needles (from alcohol).

Diphenyl dicarboxylic acid $C_6H_5.C_6H_3(CO_2H)_2$ [1:3:5]. [c. 310°]. Formed by heating benzoic aldehyde with $CH_3.CO.CO_2H$ and baryta-water (Doebner, *B.* 23, 2381; 24, 1750). Crystals, v. sl. sol. cold HOAc. Yields diphenyl on distillation with lime.—BaA″ 4½aq: needles.—CaA″.—CuA″.

Diphenyl tricarboxylic acid $C_{15}H_{10}O_6$ *i.e.* $CO_2H.C_6H_4.C_6H_3(CO_2H)_2$. Formed by fusing diphenylene ketone dicarboxylic acid with KOH (Bamberger a. Hooker, *B.* 18, 1035; *A.* 229, 160). White crystalline powder, v. sol. alcohol and ether, sl. sol. hot water.—$Pb_3A'''_2$: insoluble crystalline pp.—Ag_3A''', white pp.

References.—Amido-, Bromo-, Iodo-, Nitro-, and Oxy- diphenic and diphenyl carboxylic acids.

PHENYL-CETYL-AMINE *v.* Cetyl-aniline.

PHENYL-CHELIDAMIC ACID *v.* Chelidonic acid.

PHENYL-CHLORO-ACETIC ACID *v.* Chloro-phenyl-acetic acid.

PHENYL CHLORO-BENZYL KETONE $C_6H_5.CO.CHCl.C_6H_5$. [65°]. (Curtius, *J. pr.* [2] 44, 547). Formed by reducing phenyl dichloro-benzyl ketone with iron and acetic acid (Lachovitch, *B.* 17, 1163). V. sol. alcohol.

Phenyl di-chloro-benzyl ketone $C_6H_5.CO.CCl_2.C_6H_5$. [71°]. (Zinin, *A.* 119, 177); [61°] (L.). Formed from benzil and PCl_5. Prisms (from ether). Reduced by zinc and HCl to phenyl benzyl ketone.

PHENYL CHLORO-BENZYL SULPHONE $C_6H_5.CO.CHCl.C_6H_5$. Formed by heating benzylidene chloride with $C_6H_5.SO_2Na$ and alcohol at 150° (Otto, *J. pr.* [2] 40, 517). Needles (from HOAc), sl. sol. hot alcohol.

PHENYL-CHLORO-ETHANE *v.* Chloro-ethyl-benzene.

PHENYL CHLORO-ETHYL OXIDE *v.* *Chloro-ethyl derivative* of Phenol.

PHENYL CHLORO-ETHYL SULPHONE $C_6H_5.SO_2.CH_2.CH_2Cl$. [56°]. Formed by the action of PCl_5 or HCl on phenyl oxy-ethyl sulphone (Otto, *J. pr.* [2] 30, 197). Six-sided tablets (from benzene), sl. sol. water.

Reactions.—1. Boiling with alcohol and Ag_2O converts it into $C_6H_5.SO_2.C_2H_4OH$.—2. By heating with $C_6H_5SO_2Na$ in alcoholic solution it is converted into $(C_6H_5.SO_2)_2C_2H_4$.—3. *Sodium-amalgam* reduces it, in alcoholic solution, to benzene sulphinic acid.—4. Alcoholic NaOEt forms $C_6H_5.SO_2.C_2H_4OEt$.—5. Converted by heating in sealed tubes with dry Ag_2O and benzene into $(C_6H_5.SO_2.C_2H_4)_2O$.—6. *Ammonia* forms $(C_6H_5.SO_2.C_2H_4)_2NH$.—7. Alcoholic KHS produces $(C_6H_5.SO_2.C_2H_4)_2S$. [124°].

Phenyl chloro-ethyl sulphone $C_6H_5.SO_2.CHCl.CH_3$. [52°]. Formed by heating aqueous $CH_3.CCl_2.CO_2Na$ (1 mol.) with sodium benzene sulphinate (2 mols.) at 100° (Otto, *J. pr.* [2] 40, 532). Crystals (from alcohol).

PHENYL-CHLORO-IMESATIN *v.* Isatin.

PHENYL CHLORO-METHENYL DI-ETHYL TRI-SULPHONE $CCl(SO_2Ph)(SO_2Et)_2$. [130°]. Got by chlorinating $CH(SO_2Ph)(SO_2Et)_2$ (Laves, *B.* 25, 363). Plates, sl. sol. hot water.

TRI-PHENYL CHLORO-METHENYL TRI-SULPHONE $CCl(SO_2Ph)_3$. [260°]. Got by chlorinating $CH(SO_2Ph)_3$ (Laves, *B.* 25, 350).

PHENYL CHLORO-METHYL KETONE *v.* ω-Chloro-acetophenone.

PHENYL CHLORO-METHYL SULPHONE $C_6H_5.SO_2.CH_2Cl$. [53°]. Formed by boiling an aqueous solution of $C_6H_5SO_2Na$ (2 mols.) with $CHCl_2.CO_2Na$ (1 mol.), the yield being nearly the theoretical quantity (Otto, *J. pr.* [2] 40, 527; *B.* 21, 656). Formed also from $C_6H_5.SO_2Na$ and CH_2Cl_2.

Phenyl di-chloro-methyl sulphone $C_6H_5.SO_2.CHCl_2$. [59°]. Formed by treatment of $C_6H_5.SO_2.CH_2.CO_2H$ with Cl in diffused daylight (Otto, *J. pr.* [2] 40, 511). Monoclinic prismatic tables, v. sol. hot alcohol.

PHENYL-CHLORO-NAPHTHYL-AMINE. *Benzoyl derivative* $C_6H_5NBz.C_{10}H_6Cl$. [152°]. Formed from $NPhBz.C_{10}H_7$ and PCl_5 (Claus a. Richter, *B.* 17, 1590). Needles, sol. alcohol.

PHENYL-CHLORO-NITRO-PHENYL-HYDRAZINE $C_6H_5.N_2H_2.C_6H_3Cl(NO_2)$ [1:4:6]. [140°]. Formed from phenyl-hydrazine and $C_6H_3Cl(NO_2)_2$ in the cold (Willgerodt, *J. pr.* [2] 37, 355). Red prisms (from alcohol and ether).

PHENYL TRI-CHLORO-OXY-PROPYL KETONE $C_6H_5.COCH_2.CH(OH).CCl_3$. [6[illegible]°] and [77°]. Got from acetophenone, chloral, and HOAc (Koenigs, *B.* 25, 795). V. sl. sol. water. Converted by H_2SO_4 into $C_6H_5.CO.CH:CH.CCl_3$ [102°].

PHENYL CHLORO-PHENYL HYDRAZINE $C_6H_5.N_2H_2.C_6H_4Cl$ [1:4]. [90°]. Formed by reducing $C_6H_5.N_2.C_6H_4Cl$ with alcoholic ammonium sulphide (Heumann a. Mentha, *B.* 19, 1688).

PHENYL CHLORO-PHENYL KETONE *v.* Chloro-benzophenone.

PHENYL-CHLORO-PROPIONIC ACID *v.* Chloro-phenyl-propionic acid.

PHENYL ω-CHLORO-*p*-TOLYL KETONE $C_6H_5.CO.C_6H_4.CH_2Cl$. *Benzoylbenzyl chloride.* [98°]. Formed by chlorination of phenyl *p*-tolyl ketone at 110° (Thörner, *A.* 189, 89). Silky needles (from dilute alcohol). May be sublimed. On further chlorination at 135° it yields phenyl dichlorotolyl ketone or benzoyl benzylidene chloride $C_6H_5.CO.C_6H_4.CHCl_2$ [95°] and, at 155°, phenyl tri-chloro-tolyl ketone or benzoyl-benzotrichloride $C_6H_5.CO.C_6H_4.CCl_3$ [111°], which is converted by PCl_5 into $C_6H_5.CCl_2.C_6H_4.CCl_3$ [80°] crystallising in thin plates.

PHENYL-CHRYSYL-THIO-UREA $C_6H_5NH.CS.NH.C_{18}H_{11}$. [186°]. Formed from phenyl-thiocarbimide and chrysylamine and from chrysyl-thiocarbimide and aniline in benzene solution (Abegg, *B.* 24, 957). Crystals.

PHENYL-CINCHONIC ACID *v.* Phenyl quinoline carboxylic acid.

PHENYL-CINCHONIDINE $C_{19}H_{21}PhN_2O$. Formed in two modifications (an oil, sol. ether, and an amorphous powder, insol. ether) by heating cinchonidine with aniline (Claus a. Bätcke, *B.* 18, 2194). Both give $B''H_2PtCl_6$ 2aq.

PHENYL-CINNAMIC ACID $C_{15}H_{12}O_2$ *i.e.* $C_6H_5.CH:CPh.CO_2H$. [170°]. Formed by saponifying the nitrile or heating sodium phenyl-acetate with benzoic aldehyde and Ac_2O at 150° (Oglialoro, *G.* 9, 429). Needles, sol. alcohol and ether, v. sl. sol. cold water. Reduced by sodium-amalgam to *αβ*-di-phenyl-propionic acid.—BaA'_2 4aq: micaceous plates.

Methyl ether MeA'. [78°] (Cabella, *G.* 14, 114). Needles (from dilute alcohol).

Nitrile $C_6H_5CH:CPh.CN$. *Phenyl-styryl cyanide.* [87°]. (360° cor.). Formed by the action of benzyl cyanide on benzoic aldehyde or benzylidene chloride in presence of NaOEt or solid NaOH (Rossolymo, *B.* 22, 1235; Meyer, *A.* 250, 124; Janssen, *A.* 250, 129; Neure, *A.* 250, 155; Frost, *A.* 250, 157). White plates (from alcohol). Yields $CHPhBr.CPhBr.CN$ [130°] and $CHPhCl.CPhCl.CN$. [168°].

o-Carboxylic acid. *Imide*

$C_6H_4{<}\begin{matrix}C(CHPh).CO\\ CO\text{———}NH\end{matrix}$. [174°]. Formed by heating the imide of carboxy-phenyl-acetic acid (vol. i. p. 706) with benzoic aldehyde (Gabriel, *B.* 20, 1205). Needles.

References.—NITRO- and OXY- PHENYL-CINNAMIC ACID.

PHENYL-CINNAMYL-HYDRAZINE $CHPh:CH.CH_2.NPh.NH_2$. [54°]. Formed from sodium phenyl-hydrazine and cinnamyl bromide (Michaelis, *B.* 22, 2233). Crystals.

PHENYL-CINNAMYL KETONE *v.* PHENYL STYRYL KETONE.

PHENYL-*p*-COUMARIC ACID [1:4] $C_6H_4(OH).CH:CH.CO_2H$. [219°]. Formed by heating *p*-oxy-benzoic aldehyde with Ac_2O and sodium phenyl-acetate and boiling the resulting acetyl derivative with baryta-water (Oglialoro, *G.* 13, 173).—AgA': nearly insol. water.

Acetyl derivative. [170°].

Methyl ether MeA'. [170°].

Ethyl ether EtA'. [152°].

Methyl derivative. [189°]. Vol. iii. p. 738.

PHENYL-COUMARIN $C_{15}H_{10}O_2$. [140°]. Formed, together with $C_6H_4(OAc).CH:CPh.CO_2H$, by heating salicylic aldehyde with sodium phenyl-acetate and Ac_2O for 8 hours at 150° (Oglialoro, *G.* 9, 428). Prisms, sol. ether.

Mono-sulphonic acid $C_{15}H_9O_2(SO_3H)$ 2½aq. [263]. White needles (Curatolo, *G.* 14, 257). —BaA'_2.—PbA'_2 4aq: needles, m. sol. hot water.

Di-sulphonic acid $C_{15}H_8O_2(SO_3H)_2$ 6aq. [89°]. Deliquescent crystals.—BaA'_2 4aq: white prisms.—PbA'_2 5aq: needles, v. sol. water.

PHENYL-CROTONIC ACID $C_{10}H_{10}O_2$ *i.e.* $C_6H_5.CH:CMe.CO_2H$. *Phenyl-methacrylic acid. (α)-Methyl-cinnamic acid.* [82°]. Formed by heating benzoic aldehyde with propionic anhydride and sodium propionate (Perkin, *C. J.* 31, 391; 32, 661). Formed also by heating benzoic aldehyde with Ac_2O and sodium methyl-malonate; and by heating benzoic aldehyde with sodium propionate and HOAc or Ac_2O (Stuart, *C. J.* 43, 404; Slocum, *A.* 227, 57). Obtained also by oxidation of the corresponding aldehyde (Miller a. Kinkelin, *B.* 19, 526). It is also a product of the action of Na on benzyl propionate (Conrad a. Hodgkinson, *A.* 193, 314).

Transparent plates (from alcohol), sl. sol. hot water. When prepared by Perkin's method it appears to be accompanied by an isomeride [74°] crystallising in needles, which is converted into the acid [82°] by frequent recrystallisation (Raikoff, *B.* 20, 3396). Yields methrohol (*q.v.*) when heated with dilute H_2SO_4. Bromine forms $CHPhBr.CMeBr.CO_2H$ [137°] (Körner, *B.* 21, 276).

Salts.—BaA'_2 aq: very minute plates.—BaA'_2 4aq: small white crystals, got by slow cooling.—AgA'. S. ·374. Needles.

Methyl ether MeA'. [39°]. (254°).

Amide [128°] (Edeleano, *B.* 20, 619).

Phenyl-isocrotonic acid $C_6H_5.CH:CH.CH_2.CO_2H$. [86°] (J.); [88°] (B. a. D.). (302°). Formed by heating benzoic aldehyde with succinic anhydride and sodium succinate (Perkin), the yield being 2 p.c. (Jayne, *A.* 216, 100). Formed also by heating phenyl-trimethylene tricarboxylic acid $C_3H_2Ph(CO_2H)_3$ in a current of CO_2 at 190° (Buchner a. Dessauer, *B.* 25, 1155). Prepared by heating benzoic aldehyde with sodium succinate and Ac_2O at 125°, and separated from phenyl-paraconic acid by solution in CS_2. Long thin needles (from water) or prisms (from CS_2). When heated with H_2SO_4 (4 pts.) and water (4 pts.) it changes to the isomeric phenyl-butyrolactone and an acid [179°] (Erdmann, *A.* 227, 257). Yields *γ*-phenyl-*n*-butyric acid [49°] on reduction. Boiling NaOHAq converts it into the isomeric $C_6H_5.CH_2.CH:CH.CO_2H$ [65°]. Split up by long boiling into water and (*α*)-naphthol. Alkaline $KMnO_4$ at 0° forms di-oxy-phenyl-butyric lactone (Fittig a. Obermüller, *A.* 268, 44).—BaA'_2 3aq.—CaA'_2 3aq.—AgA': bulky pp.

α-Phenyl-crotonic acid $CH_3.CH:CPh.CO_2H$. *Methylatropic acid.* [135°]. Formed by heating sodium phenyl-acetate with paraldehyde and Ac_2O (Oglialoro, *G.* 15, 514). Minute prisms (from water), sol. alcohol and ether.—AgA': m. sol. hot water.

Phenyl-crotonic acid $C_6H_5.CH:C(CH_2Ph).CO_2H$. [158°]. Formed from sodium phenyl-propionate, benzoic aldehyde, and Ac_2O at 160° (Oglialoro, *G.* 20, 162). Needles (from alcohol).

Reference.—OXY-PHENYL-CROTONIC ACID.

PHENYL-CROTONIC ALDEHYDE *v.* PHENYL-METHACRYLIC ALDEHYDE.

PHENYL-CUMAZONIC ACID.

$C_{17}H_{15}NO_3$ *i.e.*
$C_6H_3(CO_2H){<}\begin{matrix}CMe_2.O\\ N{=\!=\!=}CPh\end{matrix}$ (?). [220°]. Formed by heating (3,4,1)-amido-oxypropyl-benzoic acid with BzCl at 100°-120° (Widmann, *B.* 16, 2585). White crystals. Sol. alcohol, insol. water.—$HA'H_2SO_4$ 2aq: thin plates.

PHENYL-CUMINYL-AMINE $C_{16}H_{19}N$ *i.e.* $C_6H_5.NH.CH_2.C_6H_4Pr$. [41°]. Formed by reducing $C_6H_5.N:CH.C_6H_4Pr$ (Uebel, *A.* 245, 289). Plates or prisms. Yields a nitrosamine $C_{16}H_{18}(NO)N$ [94°].—B'HCl: white crystals.

PHENYL-CUMINYL-THIO-UREA $C_6H_4Pr.CH_2.NH.CS.NHPh$. [100°-106°]. Formed from cuminylamine and phenyl-thio-carbimide (Goldschmidt a. Gessner, *B.* 20, 2416).

PHENYL-CUMINYL-UREA $C_{17}H_{20}N_2O$ *i.e.* $C_6H_5NH.CO.NHC_{10}H_{13}$. [144°]. Formed from cuminyl cyanate and aniline (Raab, *B.* 8, 1151) and from phenyl cyanate and cuminylamine (Goldschmidt, *B.* 20, 2415). Small needles.

PHENYL-DI-CUMYL-GUANIDINE $NPh:C(NH.C_6H_4(C_3H_7)[1:4])_2$. Formed from di-cumyl-thio-urea and aniline (Francksen, *B.* 17, 1226). Resin.

PHENYL ψ-CUMYL KETONE $C_{16}H_{16}O$ *i.e.* $C_6H_5.CO.C_6H_2Me_3$ [1:2:4:5]. (329°). From BzCl, ψ-cumene, CS_2, and $AlCl_3$ (Elbs, *J. pr.* [2] 35, 491; *cf.* Claus, *B.* 19, 2881); the yield is 65 p.c. of the calculated.

Reactions.—1. Boiling produces small quantities of needles [180°], probably (*B.* 2,3)- di methyl-anthraquinone.—2. Conc. or fuming H_2SO_4 at 100° forms benzoic acid and ψ-cumene sulphonic acid $C_6H_2Me_3(SO_3H)$ [1:2:4:5].—3. Fuming HNO_3 mixed with $H_2S_2O_7$ gives two isomeric tri-nitro- derivatives; one [185°] is v. sl. sol. alcohol, the other [155°] is m. sol. alcohol.—4. Dilute nitric acid forms benzoyl-trimellitic acid, $C_6H_5.CO.C_6H_2(CO_2H)_3$ and $C_6H_5.CO.C_6H_2Me(CO_2H)_2$.

Phenyl cumyl ketone $C_6H_5.CO.C_6H_4Pr$. (343°) at 738 mm. Formed from cuminyl chloride, benzene, and $AlCl_3$ (Smith). Yields two oxims [106°] and [132°], the latter of which forms an acetyl derivative [90°].

Phenyl *n*-cumyl ketone. $C_6H_5.CO.C_6H_4Pr$. (345° at 716 mm.). Formed from *n*-cumene, BzCl, and $AlCl_3$ (Smith, *B.* 24, 4033). Prisms. Yields two oxims [130°] and [104°], which yield acetyl derivatives, melting at 116 and 66°.

PHENYL-ψ-CUMYL-METHANE CARBOXYLIC ACID [1:2:4] $C_6H_2Me_3.CH_2.C_6H_4.CO_2H$ [1:2] [186°]. Got by reducing $C_6H_2Me.CO.C_6H_4.CO_2H$ with Zn and NH_3Aq (Gresly, *A.* 234, 238).

DI-PHENYL-ψ-CUMYL-METAPYRAZOLE TETRAHYDRIDE $C_{24}H_{26}N_2$ *i.e.*

$C_9H_{11}.CH\left\langle\begin{matrix}NPh\\NPh\end{matrix}\right\rangle C_2H_4$. [125°]. Formed from *p*-cuminic aldehyde and di-phenyl-ethylene-diamine at 100° (Moos, *B.* 20, 733). Silky needles.

PHENYL-ψ-CUMYL-UREA $C_{16}H_{18}N_2O$ *i.e.* $NHPh.CO.NHC_6H_2Me_3$ [211°]. Formed from ψ-cumidine and phenyl cyanate (Goldschmidt a. Bardach, *B.* 25, 1361). White needles.

PHENYL-CYANAMIDE *v.* vol. ii. p. 316.

Di-phenyl-cyanamide $C_{13}H_{10}N_2$ *i.e.* $C(NPh)_2$. *Carbodiphenylimide.* Mol. w. 194. (331° cor.). Formed by warming a solution of *s*-di-phenyl-thio-urea in benzene with HgO (Weith, *B.* 7, 10, 1303; 9, 810). Syrup, drying up to a vitreous mass. Changes spontaneously into an opaque polymeride [170°] resembling porcelain.

Reactions.—1. Boiling *dilute alcohol* converts it into *s*-di-phenyl-urea.—2. *Aniline* yields (α)-tri-phenyl-guanidine.—3. H_2S passed into its solution in benzene forms $CS(NHPh)_2$.—4. *s-Di-phenyl-thio-urea* at 150° forms phenyl-thiocarbimide and (α)-tri-phenyl-guanidine.—5. *Di-phenyl-urea* at 150° acts in like manner, forming phenyl cyanate and tri-phenyl-guanidine.—6. *Phenyl-hydrazine* at 120° forms the compound $C_6H_5N_2:C(NHPh)_2$ [204°] which gives the salts B'HCl, $B'_2H_2PtCl_6$, and $B'H_2SO_4$, and is converted, by heating with phenyl-hydrazine at 185°, into $C_{25}H_{22}N_6$ [200°], which gives the salts $B'_2H_4Cl_4$ and $B'_22H_2PtCl_6$. The compound $PhN_2:C(NHPh)_2$ is converted by heating with phenyl-thiocarbimide at 190° into $C_{26}H_{22}N_6S$ [175°], and by heating with di-*p*-tolyl-cyanamide into $C_{34}H_{28}N_6$ [128°], which gives the salts $B'_2H_4Cl_4$ and $B'_22H_2PtCl_6$ (Wessel, *B.* 21, 2272).—7. HCy passed into its solution in benzene forms $C_{14}H_{11}N_3$ crystallising from alcohol in prisms [137°]. A little of its solution in H_2SO_4 mixed with water is coloured deep blue by NaOH (Laubenheimer, *B.* 13, 2155).—8. *Tolylene-o-diamine* at 135° forms $C_{20}H_{20}N_4$ [161°] which yields $B'_2H_2Cl_2$ [174°] (Dahm a. Gasiorowski, *B.* 19, 3057).

Salt.—B'HCl. Needles (from benzene).

Tri-phenyl-di-cyan-di-amide $C_{20}H_{16}N_4$. Formed from NHPh.CS.NH.C(NPh).NHPh, alcohol, and HgO, and also by heating di-phenyl-guanidine at 175° (Rathke a. Oppenheim, *B.* 23, 1673). Yellow needles (containing EtOH) (from alcohol).—B'HCl. Needles, insol. water.—$B'_2H_2PtCl_6 2aq$.—$B'_2H_2SO_4 2aq$.

Reference.—OXY-PHENYL-CYANAMIDE.

PHENYL CYANATE *v.* vol. ii. p. 315.

PHENYL-CYANIC ACID *v.* CYANIC ACID.

PHENYL CYANIDE *v.* BENZONITRILE and PHENYL-CARBAMINE.

Di-phenyl dicyanide $C_{14}H_{10}N_2$ *i.e.*

$PhC\left\langle\begin{matrix}N\\N\end{matrix}\right\rangle CPh$? [152°]. Formed from benzamidine and benzoic aldehyde (Pinner, *B.* 22, 1610; 23, 2925). Prisms. Changes at 260°–270° into cyaphenine.

PHENYL-CYANURIC ACID *v.* *Cyanuric acid* in the article on CYANIC ACID.

PHENYL-*p*-CYMYL-CARBINOL $C_6H_5.CH(OH).C_6H_3(CH_3)(C_3H_7)$ [1:2:5]. (327° uncor.). Formed by reduction of phenyl *p*-cymyl ketone (Claus a. Elbs, *B.* 18, 1798; *J. pr.* [2] 35, 497). Thick colourless oil.

PHENYL *p*-CYMYL KETONE $C_{17}H_{18}O$ *i.e.* $C_6H_5.CO.C_6H_3MePr$ [1:2:5]. (224° at 40 mm.); (340°) at 760 mm.

Formation.—1. From cymene by heating with benzoic acid and P_2O_5 (Kollarits a. Merz, *B.* 6, 546).—2. From cymene, BzCl, and zinc (Grucarevic a. Merz, *B.* 6, 546, 1246).—3. From cymene, BzCl, CS_2, and $AlCl_3$ (Elbs, *J. pr.* [2] 35, 494].

Properties.—Yellowish oil, v. sol. alcohol and ether, m. sol. HOAc. Very slightly volatile with steam.

Reactions.—1. *Bromine* and *iron powder* at 140° give benzoic acid and bromo-cymene, $C_6H_3BrMePr$ [1:2:5] [232°].—2. Conc. H_2SO_4 and KNO_3 give an amorphous dinitro-derivative.—4. Dilute HNO_3 gives benzoyl-terephthalic acid.—5. Concentrated H_2SO_4 at 100° gives benzoic acid and cymene sulphonic acid, $C_6H_3MePr(SO_3H)$ [1:4:2].

PHENYL-CYSTEÏNE $C_9H_{11}NSO_2$ *i.e.* $CH_3.C(SPh)(NH_2).CO_2H$. Formed by boiling phenyl-mercapturic acid with dilute H_2SO_4 (Baumann a. Preusse, *H.* 5, 337). Plates (from NH_3Aq) or six-sided tables (from water), v. sol. acids and alkalis, sl. sol. cold water. Yields phenyl mercaptan on boiling with NaOHAq.

Reference.—BROMO-PHENYL-CYSTEÏNE.

PHENYL-DECOIC ACID. *Nitrile* $C_6H_5.CH(C_8H_{17}).CN$. (328°). Formed from benzyl cyanide, octyl iodide, and NaOH (Rossolymo, *B.* 22, 1237). Yellow oil.

PHENYL-DURYL-CARBINOL [6:4:3:2:1] $C_6HMe_4.CH(OH).C_6H_5$. (above 360°). Formed by reduction of phenyl iso-duryl ketone

Essner a. Gossin, *Bl.* [2] 42, 172). Liquid. Yields an *acetyl derivative* boiling above 360° and a *benzoyl derivative* [75°].

DI-PHENYL DURYLENE DIKETONE $C_{24}H_{22}O_2$ *i.e.* $(C_6H_5.CO)_2C_6Me_4$. [270°]. (above 380°). Formed from durene, BzCl, and $AlCl_3$ Friedel a. Crafts, *A. Ch.* [6] 1, 512). Prisms.

PHENYL DURYL KETONE $C_{17}H_{18}O$ *i.e.* $C_6H_5.CO.C_6HMe_4$. [119°]. (343°) at 725 mm. Got from durene, BzCl, and $AlCl_3$ (Friedel a. Crafts, *A. Ch.* [6] 1, 511). Acicular prisms, v. sol. warm alcohol. Reduced by HI and P to $C_{17}H_{20}$ 60·5°] (310° at 716 mm.). Br forms $C_{17}H_{15}Br_3O$ 225°] and other products.

Phenyl isoduryl ketone. [63°]. (300°). Formed by the action of BzCl and $AlCl_3$ on the isodurene derived from toluene (Essner a. Gossin, *Bl.* [2] 42, 170). Successive treatment with HCy and alcoholic potash gives the acid $C_6HMe_4.CPh(OH).CO_2H$, sol. water and alcohol.

PHENYLENE. The radicle C_6H_4.

PHENYLENE-ACETAMIDINE

$C_6H_4<{NH \atop N}\gg C.CH_3$. [170°] (H.); [175°] (L.).

Formed by boiling phenylene-*o*-diamine with HOAc, or by reducing $C_6H_4(NO_2)(NHAc)$ with tin and HCl (Ladenburg, *B.* 8, 677; Hübner, *A.* 209, 353). Needles.—$B'HCl$.—$B'_2H_2PtCl_6$ aq.—$B'HNO_3$.—$B'H_2SO_4$.

Phenylene-di-acetamidine $C_{10}H_{14}N_4$ *i.e.* [1:4] $C_6H_4(CH_2.C(NH).NH_2)_2$. [182°]. Formed by the action of alcoholic NH_3, followed by NaOHAq, upon the hydrochloride of phenylene-di-acetimido-ether (Glock, *B.* 21, 2660). Plates.

***o*-PHENYLENE-DI-ACETIC ACID** $C_{10}H_{10}O_4$ *i.e.* [1:2] $C_6H_4(CH_2.CO_2H)_2$. Mol. w. 194. [150°]. Formed by saponification of its nitrile by boiling with dilute H_2SO_4 (Baeyer a. Pape, *B.* 17, 447). Slender needles, v. sol. alcohol, m. sol. cold water.—Ag_2A'': insoluble pp.

Nitrile $C_6H_4(CH_2.CN)_2$. [60°]. Formed by the action of KCy on di-ω-bromo-*o*-xylene.

***m*-Phenylene-di-acetic acid** $C_6H_4(CH_2.CO_2H)_2$. [170°]. Formed by boiling its nitrile with alcoholic potash (Kipping, *C. J.* 53, 42; *B.* 21, 42). Needles, v. sol. water.—Ag_2A'': white pp.

Nitrile $C_6H_4(CH_2.CN)_2$. [29°]. (308° at 300 mm.). From [1:3] $C_6H_4(CH_2Br)_2$ and KCy.

***p*-Phenylene-di-acetic acid** $C_6H_4(CH_2.CO_2H)_2$. [241°]. Got from its nitrile (Biedermann, *B.* 5, 703; Klippert, *B.* 9, 1766; Kipping, *C. J.* 53, 44). Needles, m. sol. water.—CaA'' 2aq.—CaA'' 3aq.—BaA'' 2½ aq: needles, v. sol. water.—ZnA''.—CuA''.—Ag_2A'': white amorphous pp.

Ethers.—Me_2A''. [57°].—Et_2A''. [58°].

Chloride. Oil (Klippert).

Amide. [above 290°]. Plates and needles.

Nitrile $C_6H_4(CH_2.CN)_2$. [96°]. Formed by the action of KCy on $C_6H_4(CH_2Br)_2$ or $C_6H_4(CH_2Cl)_2$. Three-sided prisms (from ether). Alcoholic ammonium sulphide at 100° converts it into $C_6H_4(CH_2.CS.NH_2)_2$ [206°] which crystallises from HOAc.

Di-phenylene-acetic acid ${C_6H_4 \atop C_6H_4}>CH.CO_2H$. [222°]. Formed by heating $C_{12}H_8:C(OH).CO_2H$ with HI and P at 140° (Friedländer, *B.* 10, 536). Small crystals (from alcohol). Decomposed by heating with soda-lime into CO_2 and fluorene.—AgA': unstable pp.

Ethyl ether EtA'. [165°].

Reference.—OXY-DIPHENYLENE-ACETIC ACID.

***p*-PHENYLENE DI-ACETIMIDO-ETHER** $C_6H_4(CH_2.C(NH).OEt)_2$. The hydrochloride $B''2HCl$ [above 240°] formed by the action of alcohol and HCl on $C_6H_4(CH_2.CN)_2$, crystallises in needles (Glock, *B.* 21, 2660). It is insol. ether.

***o*-PHENYLENE-DI-ACRYLIC ACID** $C_6H_4(CH:CH.CO_2H)_2$. [above 300°]. Formed by boiling $C_6H_4(CH_2.CCl(CO_2Et)_2)_2$ with alcoholic potash (Perkin, *C. J.* 53, 14; *B.* 19, 435). Sl. sol. water, v. sl. sol. alcohol.—Ag_2A'': pp.

***p*-Phenylene di-acrylic acid** $C_6H_4(CH:CH.CO_2H)_2$. [310°]. Obtained by saponifying the mono-ethyl ether HEtA'' [200°] which is got by heating *p*-aldehydo-cinnamic ether with NaOAc and Ac_2O (Löw, *A.* 231, 377). Got also by boiling $C_6H_4(CH_2.CBr(CO_2Et)_2)_2$ with alcoholic potash (Kipping, *C. J.* 53, 41). Yields a tetrabromide crystallising in needles.—Ag_2A''.

PHENYLENE-DI-ALLYL-DI-THIO-DI-UREA $C_6H_4(NH.CS.NHC_3H_5)_2$. The *o*- [159°], *m*- [105°], and *p*- [200°] compounds are formed by heating the corresponding phenylene-diamines with alcohol and allyl-thiocarbimide (oil of mustard) at 100° (Lellmann a. Würthner, *A.* 228, 201). The *o*- and *p*- compounds decompose when heated. They are all sol. HOAc.

***o*-PHENYLENE-DI-AMIDO-DI-ACETIC ACID** [1:2] $C_6H_4(NH.CH_2.CO_2H)_2$. The ether Et_2A'' [135°] is got from *o*-phenylene diamine and $ClCO_2Et$ (Zimmermann a. Knyrim, *B.* 16, 515).

m*-Phenylene-di-amido-di-acetic acid** [1:3] $C_6H_4(NH.CH_2.CO_2H)_2$. The ***ethyl ether Et_2A'' [78°] is got by heating *m*-phenylene-diamine with $CH_2Cl.CO_2Et$ (Zimmermann *B.* 15, 518; 16, 514). It is converted by conc. HClAq into crystalline $H_2A''H_2Cl_2$, v. sol. water.

***p*-Phenylene-di-amido-di-acetic acid.** The ethyl ether Et_2A'' [83°] and the hydrochloride $H_2A''H_2Cl_2$ are formed in like manner from *p*-phenylene-diamine.

***o*-PHENYLENE-DIAMINE** [1:2] $C_6H_4(NH_2)_2$. Mol. w. 108. [104°]. (252°). Prepared by reducing *o*-nitro-aniline with tin and HCl (Zincke a. Sintenis, *B.* 6, 123; Vignon, *Bl.* [3] 2, 675; Sandmeyer, *B.* 19, 2654). Formed also by heating the corresponding di-amido-benzoic acids with baryta (Griess, *J. pr.* [2] 3, 143; Salkowski, *A.* 173, 58) and by the action of tin and HCl on bromo-*o*-nitro-aniline (Wurster, *A.* 171, 63; Hübner, *A.* 209, 360) and on *o*-di-nitro benzene (Zincke, *B.* 7, 1874). Plates (from water) or tables (from chloroform), v. e. sol. hot water, alcohol, and ether.

Reactions.—1. $FeCl_3$ added to a solution of the hydrochloride forms di-amido-phenazine hydrochloride, which crystallises in ruby-red needles $C_{12}H_{10}N_4HCl$ (Fischer, *B.* 22, 355).—2. *Pyrocatechin* at 200° forms phenazine $C_6H_4:N_2:C_6H_4$.—3. (β)-*Naphthoquinone* forms naphthophenazine $C_{10}H_6:N_2:C_6H_4$.—4. *Cyanogen* gas forms $C_8H_6N_4$ a yellow crystalline powder [c. 280°], sl. sol. water, forming $B'_2H_2PtCl_6$ 3aq and $B'_2H_2PtCl_6$ aq. By heating with HCl it is converted into $C_8H_7N_3O$ [280°] and di-oxy-quinoxaline (Bladin, *Bl.* [2] 42, 104; *B.* 18, 672).—5. The *sulphocyanide* is converted by heat into a mixture of phenylene-thio-urea and thio-urea (Lellmann, *A.* 221, 8).—6. KNO_2 added to a very dilute solution of the sulphate forms 'amidoazophenylene' $C_6H_4N_3$, [illegible] from benzene in pearly white needles [98·5°] (Ladenburg, B. 9, 219).—7. ICy forms $C_{12}H_{12}N_4$, which yields the salts $B''H_2Cl_2$, $B''HCl\,2\frac{1}{2}aq$, $B''2HNO_3\,2\frac{1}{2}aq$, and $B''H_2SO_4\,2\frac{1}{2}aq$, and the benzoyl derivative $C_{12}H_{11}BzN_4$, and is converted by nitrous acid into $C_{12}H_8N_6O_2$ (Hübner, *B.* 9, 778; 10, 1716).—8. The hydrochloride is converted by benzoic aldehyde into dibenzylidene-phenylene diamine $(C_6H_4(N{:}CHPh)_2$ [134°], yielding $B'_2H_2PtCl_6$, $B'HNO_3$, $B'H_2SO_4$, $B'MeI$, and $B'EtI$ [213°] (Ladenburg, *B.* 11, 1658).

Salts.—$B''2HCl$. Needles, v. sol. water.—$B''H_2PtCl_6$.—$B''_2H_2SO_4$.—$B''H_2SO_4\,1\frac{1}{2}aq$: plates.

Di-acetyl derivative $C_6H_4(NHAc)_2$. [186°]. Long silky needles, v. sol. hot water and alcohol (Bistrzycki, *B.* 23, 1878).

Benzoyl derivative $C_6H_4(NH_2)(NHBz)$. [140°]. Got by reducing $C_6H_4(NO_2)(NHBz)$ with ammonium sulphide (Mixter, *Am.* 6, 26). Minute crystals, sol. water. When the reduction is effected by tin and HCl the product is benzenyl-phenylene-diamine (*q. v.*).

Dibenzoyl derivative $C_6H_4(NHBz)_2$. [c. 300°]. Thin prisms (from HOAc) (Bistrzycki).

Di-p-toluyl derivative $C_6H_4(NH.CO.C_6H_4Me)_2$. [228°]. Got, together with tolenyl-benzamidine $C_6H_4{:}N_2H{:}C.C_6H_4Me$ [268°], by the action of *p*-toluyl chloride on *o*-phenylene-diamine dissolved in benzene (Hübner, *A.* 210, 328). Colourless needles, sl. sol. alcohol.

***m*-Phenylene-diamine** $C_6H_4(NH_2)_2$. [63°]. (277° i.V.). Prepared by reduction of *m*-di-nitro-benzene or *m*-nitro-aniline (Hofmann, *Pr.* 11, 518; 12, 639; Zincke, *B.* 5, 792). Formed also by heating *s*-di-amido-benzoic acid with baryta (Wurster, *B.* 7, 214; Hübner, *A.* 222, 86), and by the action of tin and HCl on (4,2,1)-di-nitro-benzoic acid (Wurster, *B.* 7, 149) and on (1,2,4)-bromo-di-nitro-benzene (Z.). Got also by heating resorcin (1 pt.) with ammoniacal $CaCl_2$ (4 pts. containing 35 p.c. NH_3) for eight hours at 275° (Seyewitz, *C. R.* 109, 814). Crystalline, m. sol. water, v. sol. alcohol and ether. Its solutions are alkaline in reaction. KNO_2 added to a solution of a salt of *m*-phenylene-diamine forms a brown pp. containing $C_6H_3(NH_2)_2.N_2.C_6H_4.NH_2$. A solution in dilute H_2SO_4 is coloured yellow by a trace of nitrous acid. Aldehyde added to an alcoholic solution of *m*-phenylene-diamine hydrochloride forms an orange-red colour, with a green fluorescence. From this liquid NH_3Aq ppts. di-methyl-phenanthroline tetrahydride $C_{14}H_{16}N_2$ (Girard a. Roques, *C. R.* 107, 1158; Schiff, *A.* 253, 328). Benzoic aldehyde in alcohol forms with the hydrochloride the base $CHPh(C_6H_4(NH_2)_2)_2$. The hydrochloride of *m*-phenylene-diamine gives a crimson colour when boiled with oxygenated water (Denigès); in presence of ammonia the liquid becomes blue, but is turned red by NaOHAq. Hydrogen peroxide gives a bluish-green tint (Cazeneuve, *Bl.* [3] 5, 855). PbO_2 and dilute HOAc give a brown colour (Lauth, *C. R.* 111, 975). Alkaline NaOBr gives a maroon-red pp. (Denigès, *C. R.* 107, 662). CS_2 in alcohol at 35° forms yellow monoclinic prisms of $C_6H_4<\substack{NH\\NH}>CS$ and several other bodies (Gucci, *G.* 17, 523, 2657). The sulphocyanide is converted by heat into $C_6H_4(NH.CS.NH_2)_2$ (Lellmann, *A.* 221, 8). *m*-Phenylene-diamine is somewhat less poisonous than the *p*- isomeride (Dubois a. Vignon, *C. R.* 107, 533).

Salts.—$B''HCl$. Needles, v. sol. water, sl. sol. conc. HClAq.—$B''2HCl$.—$B''H_2PtCl_6$: needles.—$B''H_2Sn_2Cl_8$ (Gerdemann, *Z.* [2] 1, 51).—$B''H_2SnCl_6$.—$B''H_2SO_4$.

Hydriodide: Mills, *C. J.* 17, 153.

Di-formyl derivative $C_6H_4(NH.CHO)_2$. [155°]. Small crystals (Tobias, *B.* 15, 2447).

Mono-acetyl derivative $C_6H_4(NH_2)(NHAc)$. Crystalline solid, v. sol. water (Wallach a. Schulze, *B.* 15, 3020).—$B'HCl$. [280°].

Di-acetyl derivative $C_6H_4(NHAc)_2$. [189°] (Kelbe, *B.* 16, 1200; *cf.* Barbaglia, *B.* 7, 1257).

Mono-benzoyl derivative $C_6H_4(NH_2)(NHBz)$. [125°] (Bell, *B.* 7, 498); [260°] (Hübner, *A.* 208, 298). Got by reducing $C_6H_4(NO_2).NHBz$.—$B''HCl$.—$B''H_2SO_4$. Needles.

Di-benzoyl derivative $C_6H_4(NHBz)_2$. [240°] (Ruhemann, *B.* 14, 2651; Hinsberg, *A.* 254, 255). White plates.

m-Amido-benzoyl derivative $C_6H_4(NH_2)(NH.CO.C_6H_4NH_2)$. [129°]. Needles (from dilute alcohol) (Hugh, *B.* 7, 1268).

o-Oxy-benzoyl derivative $C_6H_4(NH_2).NH.CO.C_6H_4.OH$. [143°]. Crystals (Bell, *C. J.* 28, 1201).

***p*-Phenylene-diamine** $C_6H_4(NH_2)_2$. [140°]. (267°).

Formation.—1. By reduction of *p*-nitro-aniline and of *p*-di-nitro-benzene (Hofmann, *Pr.* 11, 518; 12, 639; Zincke, *B.* 7, 871).—2. By reduction of $C_6H_5.N_2.C_6H_4NH_2$ (Martius a. Griess, *Z.* 1866, 136).—3. By distilling (5,2,1)-di-amido-benzoic acid (Griess, *B.* 5, 201).—4. In the preparation of induline by heating $C_6H_5.N_2.C_6H_4.NH_2$ with aniline hydrochloride (Witt; Fischer a. Hepp, *B.* 23, 839).

Preparation.—From acetanilide by nitration and reduction with tin and HCl.

Properties.—Plates (by sublimation) or monoclinic crystals (from water) changing in the solution to trimetric plates. M. sol. water, v. sol. alcohol and ether. Forms a hydrate $C_6H_8N_2\,2aq$ [80°]. With PbO_2 and aqueous HOAc it gives a bright bluish-green colour (Lauth, *C. R.* 111, 975). *p*-Phenylene-diamine is very poisonous (Vignon, *C. R.* 107, 533). A mere trace of a mixture of *m*- and *p*- phenylene-diamine gives on warming with HOAc and $K_2Cr_2O_7$ a blue colour, changing on boiling to red (Witt, *C. J.* 35, 356; Meldola, *C. J.* 51, 105).

Reactions.—1. *Oxidised* to quinone by H_2SO_4 and MnO_2. Quinone is also formed together with NH_3 by oxidation of the sulphate with $K_2Cr_2O_7$ (Meldola a. Evans, *C. J. Proc.* 5, 115).—2. When exposed to *air*, O, H_2O_2, or K_3FeCy_6 *p*-phenylene-diamine and its salts are oxidised to $C_6H_6N_2$ a feeble red base with green lustre [230°] yielding $C_6H_5AcN_2$ [294°] (Bandrowski, *M.* 10, 126).—3. *Chlorine* passed into a solution in HOAc forms tetra-chloro-quinone.—4. $FeCl_3$ added to a solution of the hydrochloride saturated with H_2S ppts. Lauth's violet, which is v. sol. pure water, but ppd. by salts (Lauth, *C. R.* 82, 1441).—5. Potassium nitrite added to a solution of the hydrochloride forms $C_6H_4(NH_2Cl)N_2Cl$, and in presence of a large excess of HCl it forms $C_6H_4(N_2Cl)_2$.—6. Mixed with *aniline* (2 mols.) and oxidised by $K_2Cr_2O_7$ it yields pheno-safranine.—7. The *sulphocyanide* is converted by heat into $C_6H_4(NH.CS.NH_2)_2$ (Lellmann, *A.* 221, 8).—8. *Bleaching-powder* solution added to a solution in HClAq ppts. yellowish-white quinone di-chloro-di-imide which detonates at 124° (Krause, *B.* 12, 47).—9. *Aceto-acetic ether* at 170° forms $C_{14}H_{16}N_2O_4$ [176°] which is probably $C_6H_4(NH.CO.CH_2.CO.CH_3)_2$ (Knorr, *B.* 17, 545; 19, 3303).

Salts.—$B''H_2Cl_2$. Triclinic tables, v. sol. water, almost insol. HClAq.—$B''H_2PtCl_6$.—$B''H_2Sn_2Cl_6$ (Hübner, *A.* 209, 366).—$B''H_2Br_2$.—$B''H_2S_2O_6$ (Bernthsen, *A.* 251, 62).—$B''H_2SO_4$. Micaceous plates, sl. sol. water (Vignon, *Bl.* [2] 50, 152).—$B''H_2C_2O_4$. S. ·15 at 15°.

Di-formyl derivative $C_6H_4(NH.CHO)_2$. [204°]. Amorphous mass (Wundt, *B.* 11, 828).

Mono-acetyl derivative $C_6H_4(NH_2)(NHAc)$. [161°]. Formed by reduction of $C_6H_4(NO_2).NHAc$ with iron and acetic acid (Nietzki, *B.* 17, 343). Needles, sl. sol. cold water.—$B'_2H_2PtCl_6$.

Di-acetyl derivative $C_6H_4(NHAc)_2$. [above 295°]. Formed by boiling the base with HOAc (Biedermann a. Ledoux, *B.* 7, 1531). Small octahedra, sol. HOAc.

Benzoyl derivative $C_6H_4(NH_2)(NHBz)$. [128°]. Formed by reducing benzoyl-*p*-nitro-aniline (Hübner, *A.* 208, 295). Plates, sl. sol. water.—B'HCl.—$B'_2H_2SO_4$. Needles.

Di-benzoyl derivative $C_6H_4(NHBz)_2$. [above 300°]. Formed from the base, BzCl, and NaOHAq (Hinsberg, *A.* 254, 254). Plates. Yields a nitro- product [251°].

o-Oxy-benzoyl derivative $C_6H_4(NH_2)(NH.CO.C_6H_4.OH)$. [158°]. Glittering needles (Bell).

Hexahydride $C_6H_{10}(NH_2)_2$. *Di-amido-hexamethylene.* Formed by reducing the di-oxim of quinone tetrahydride in alcohol with Na (Baeyer a. Noyes, *B.* 22, 2172). Liquid, with faint ammoniacal odour, forming crystalline salts and an acetyl derivative melting above 310°.

References.—BROMO-, BROMO-NITRO-, CHLORO-, NITRO-, and OXY- PHENYLENE-DIAMINE.

PHENYLENE-DIAMINE SULPHONIC ACID *v.* DI-AMIDO-BENZENE SULPHONIC ACID.

PHENYLENE-DI-AMYL-DIAMINE [1:4] $C_6H_4(NH.C_5H_{11})_2$. [49°]. Colourless crystals (Baeyer a. Noyes, *B.* 22, 2173).

DIPHENYLENE-AZONE

$\begin{array}{l}C_6H_4.N\\C_6H_4.N\end{array}$ [156°].

Formed, together with $C_{12}H_8N_2O_2$ [240°] and $C_{12}H_8N_2O$ [152°] by boiling di-*o*-nitro-diphenyl with alcohol and zinc-dust (Täuber, *B.* 24, 3081, 3883). Greenish-yellow needles by sublimation, not volatile with steam. Almost insol. water, v. sol. alcohol, m. sol. ether, v. e. sol. HOAc. Reduced by tin and HCl to $C_{12}H_{10}N_2HCl$, which crystallises in white needles, rapidly re-oxidised by air to diphenylene-azone.

Salts.—B'HCl. Flat bronzed prisms.—$B'HAuCl_4$.—$B'_2H_2PtCl_6$: yellow needles.—$B'H_2CrO_4$.—$B'C_6H_3N_3O_7$. [194°]. Brown needles.

PHENYLENE-BENZALDEHYDINE *v.* vol. i. p. 109.

PHENYLENE-BENZAMIDINE *v.* BENZENYL-PHENYLENE-DIAMINE.

PHENYLENE-DI-BENZIDENE-DIAMINE *v.* DI-BENZYLIDENE-PHENYLENE-DIAMINE.

PHENYLENE-BENZYL-*m*-DIAMINE $C_6H_4(NH_2).NHC_7H_7$. Formed by reducing benzyl-*m*-nitro-aniline (Meldola a. Coste, *C. J.* 55, 597). Oil.—$B''2HCl$: hexagonal tablets. $FeCl_3$ colours its solution red and gives a white pp. on heating.

Di-benzoyl derivative $C_6H_4(NHBz).NBz.C_7H_7$. [178°]. Sol. alcohol.

Phenylene-benzyl-*p*-diamine. [30°]. Got by reducing benzyl-*p*-nitro-aniline (Meldola a. Coste, *C. J.* 55, 590) or *p*-nitroso-benzyl-aniline (Boeddinghaus, *A.* 263, 302). Wax-like mass of crystals, turning red in air. When mixed with the *m*-isomeride it yields di-benzyl-amido-indamine on oxidation.—$B''2HCl$. White plates, v. sol. water. $FeCl_3$ colours its aqueous solution green, changing to red. After saturation with H_2S it gives a blue pp. with $FeCl_3$.

Di-acetyl derivative. [117°]. Prisms.

Di-benzoyl derivative. [124°]. Needles.

Phenylene-di-benzyl-diamine *v.* vol. i. p. 501.

Phenylene-tetra-benzyl-*m*-diamine $C_6H_4(N(C_7H_7)_2)_2$. [81°]. Formed by heating phenylene-*m*-diamine with NaOHAq and benzyl chloride. Amorphous powder, sol. HOAc.

Phenylene-tetra-benzyl-*p*-diamine. [149°]. White crystalline powder. HOAc and CrO_3 form a blue-violet colouring matter.

PHENYLENE - BENZYLIDENE - DI - METHYL-DIAMINE $C_{15}H_{16}N_2$ *i.e.* $C_6H_5.CH:N.C_6H_4.NMe_2$. [93°] (Calm, *B.* 17, 2940); [101°] (Köhler, *A.* 241, 361). Formed from phenylene-di-methyl-*p*-diamine and benzoic aldehyde.—$B''2HCl$.

PHENYLENE - BENZYL - DI - METHYL - DIAMINE $C_6H_5CH_2.NH.C_6H_4.NMe_2$. [48°]. Formed by reducing the preceding body in alcohol with sodium-amalgam (Köhler, *A.* 241, 361). Plates. Yields a nitrosamine [128°].

PHENYLENE-BLUE or *Lauth's violet* *v.* AMIDO-IMIDO-DI-PHENYL-SULPHIDE.

PHENYLENE - BROMO - ACETYLENE - KETONE *v.* BROMO-OXY-INDONAPHTHENE.

DI-PHENYLENE-BUTANE

$\begin{array}{l}C_6H_4.CH.CH_2\\CH_2.CH.C_6H_4\end{array}$

Diphensuccindene. [100°]. Formed by heating (β)-di-phenyl-succinic anhydride with HI and P and 180° (Roser, *A.* 247, 156). White needles.

PHENYLENE-ISOBUTYL-*p*-DIAMINE $C_4H_9NH.C_6H_4.NH_2$. [39°]. Formed by reduction of *p*-nitroso-isobutyl-aniline (Wacker, *A.* 243, 299). Plates (from benzene-ligroïn).

PHENYLENE - BUTYLIDENE - *o* - DIAMINE

$C_6H_4\!<\!\begin{array}{l}NH\\NH\end{array}\!>\!CHPr$. [233°]. Formed from phenylene-*o*-diamine and isobutyric aldehyde (Lassar-Cohn, *B.* 22, 2724). Needles (by sublimation).—B'HCl. [184°].—$B'_2H_2PtCl_6$.

The isomeric compound from phenylene-*m*-diamine melts at 216°, while that from phenylene-*p*-diamine is oily, and yields $B'_2H_2PtCl_6$.

DI - PHENYLENE - ISOBUTYL - QUINOXALINE

$\begin{array}{l}C_6H_4.C:N\\C_6H_4.C:N\end{array}\!>\!C_6H_3.CH_2Pr$. [147°]. Formed from phenanthraquinone in HOAc and isobutyl-phenylene-diamine in alcohol (Gelzer, *B.* 20, 3256). Yellowish needles.—B'HCl: needles.

***o*-PHENYLENE-DICARBAMIC ETHER** $C_6H_4(NH.CO_2Et)_2$. [88°]. Formed by heating o-phenylene-diamine with $ClCO_2Et$ (Snape, *C. J.* 49, 259). Needles (from alcohol).

***m*-Phenylene-dicarbamic ether.** [145°].

***p*-Phenylene-dicarbamic ether.** [193°]. Got *by heating p-phenylene dicyanate with alcohol* (Gattermann a. Wrampelmeyer, *B.* 18, 2605).

Di-phenylene-dicarbamic acid. *Ethyl ether* $CO_2Et.NH.C_6H_4.C_6H_4.NH.CO_2Et$. [230°]. Formed from benzidine and $ClCO_2Et$ or by boiling diphenylene dicyanate with alcohol (Snape, *C. J.* 49, 256; Schiff a. Vanni, *A.* 258, 369).

Di-phenyl ether. [c. 240°]. Made by heating diphenylene dicyanate with phenol at 140° (Snape). Tables, sl. sol. alcohol.

DI-PHENYLENE CARBINOL $C_{13}H_{10}O$ *i.e.*

$\substack{C_6H_4\\C_6H_4}{>}CH.OH$. *Fluorene alcohol.* [153°]. Formed by reducing diphenylene ketone with sodium-amalgam (Barbier, *A. Ch.* [5] 7, 504). Hexagonal plates (from benzene). Oxidised by CrO_3 to diphenylene ketone. Ac_2O at 100° forms an acetyl derivative [75°]. When heated above its melting-point, diphenylene carbinol yields $C_{26}H_{18}O$ [290°], a nearly colourless resin.

***o*-PHENYLENE CARBONATE** $C_6H_4CO_3$. [118°]. (225°–230°). Formed from sodium pyrocatechin and $ClCO_2Et$ (Wallach, *A.* 226, 84). Four-sided prisms (from alcohol-benzene).

***m*-Phenylene carbonate**

$C_6H_4{<}\substack{O\\O}{>}CO$. Formed by heating resorcin with cyanuric acid and $ZnCl_2$, and also by the action of $COCl_2$ on resorcin (Birnbaum, *B.* 14, 1753). Amorphous solid, sol. HOAc.

***m*-PHENYLENE DICARBONIC ETHER** $C_6H_4(O.CO_2Et)_2$. (298°–302°). Formed from sodium resorcin and $ClCO_2Et$ in ether (Wallach, *A.* 226, 84). The *p*-isomeride, [100°], (310°), is got in like manner from hydroquinone (Bender, *B.* 13, 697).

PHENYLENE-CHLORO-OXY-ACETYLENE KETONE *v.* Chloro-di-oxy-indonaphthene.

PHENYLENE-CINNAMYLIDENE-DI-METHYL-DI-AMINE $C_{17}H_{18}N_2$ *i.e.* $C_6H_5.CH:CH.CH:N.C_6H_4.NMe_2$. [141°]. Formed from cinnamic aldehyde and phenylene-di-methyl-*p*-diamine (Nuth, *B.* 18, 575). Needles.

PHENYLENE-CUMINYLIDENE-DI-METHYL-DIAMINE $C_{18}H_{22}N_2$ *i.e.* $C_3H_7.C_6H_4.CH:N.C_6H_4.NMe_2$. [100°]. Formed from cuminol and phenylene-di-methyl-diamine (Nuth, *B.* 18, 575; Uebel, *A.* 245, 299). Needles.

***m*-PHENYLENE DICYANATE** $C_6H_4(N:CO)_2$. [51°]. Got by distilling *m*-phenylene-dicarbamic ether (Bender, *Bn.* 3, 897). Crystals.

***p*-PHENYLENE DI-CYANATE** $C_6H_4(N:C:O)_2$. [91°]. (231° at 745 mm. i.V.). V.D. 5·79 (for 5·54). Prepared by passing a stream of carbonyl chloride $COCl_2$ through *p*-phenylene-diamine hydrochloride heated to 200°–250° (Gattermann a. Wrampelmeyer, *B.* 18, 2604). Colourless needles. Sublimable. Pungent vapour. Reacts like phenyl-cyanate, forming di-ureas with amines, and di-carbamic ethers with alcohols.

PHENYLENE DI-CYANIDE *v.* *Nitrile of* Phthalic acid.

PHENYLENE ETHYL-ACETAMIDINE

$C_6H_4{<}\substack{NEt\\N}{>}C.CH_3$. [180°]. Formed by the action of Ac_2O on phenylene-ethyl-*o*-diamine (Hempel, *J. pr.* [2] 39, 200; 41, 166). Plates.

PHENYLENE-ETHYL-*o*-DIAMINE $C_6H_4(NH_2)(NHEt)$. (249°). Formed by reducing *o*-nitro-ethylaniline with tin and HCl (Hempel, *J. pr.* [2] 39, 199; 41, 164). *Oil, turning red in air and light.*

Acetyl derivative $C_6H_8N_2EtAc$. [104°].

Phenylene-ethyl-*m*-diamine $C_6H_4(NH_2)(NHEt)$. (276° uncor.). Oil, formed in like manner (Nölting a. Stricker, *B.* 19, 546). $B''H_2Cl_2$: white powder.

Phenylene-ethyl-*p*-diamine. (270°). Oil, sol. benzene (Nölting a. Collin, *B.* 17, 267; Schweizer, *B.* 19, 149; Fischer a. Hepp, *B.* 19, 2994; Bernthsen a. Goske, *B.* 20, 930).—$B''H_2SO_4$: needles or prisms.—$B''H_2Cl_2$. Plates, v. sol. water.—$B''H_2PtCl_6$.

Phenylene-di-ethyl-*m*-diamine $C_6H_4(NH_2)(NEt_2)$. (277°). Formed by reducing *m*-nitro-di-ethyl-aniline (N. a. S.; Groll, *B.* 19, 200). Oil.

Phenylene-di-ethyl-*p*-diamine. (261° uncor.). Formed by reducing nitroso-diethyl aniline or $C_6H_4(NEt_2).N_2.C_6H_4.NEt_2$ (Lippmann a. Fleissner, *B.* 16, 1424). Oil.—$B'H_2Cl_2PtCl_4$. Red crystals.—$B''ZnCl_2$ 2aq. Converted by treatment in aqueous solution with aluminium sulphate, $Na_2S_2O_3$, and $K_2Cr_2O_7$ into $NEt_2.C_6H_3(NH_2).S.SO_3H$ [229°], whence by diazo-

tisation $C_6H_3(NEt_2){<}\substack{N_2\\S}$ [107°] may be got (Bernthsen, *A.* 251, 1).

Phenylene-*s*-di-ethyl-*p*-diamine. *Nitrosamine* $C_6H_4(NEt.NO)_2$. [90°]. Formed from *p* phenylene-diamine by successive treatment with EtBr and HNO_2 (Nietzki, *B.* 16, 465). Yellowish plates (from benzene-ligroïn).

Phenylene-tetra-ethyl-*p*-diamine $C_6H_4(NEt_2)_2$. [52°]. (280° uncor.). Got by heating phenylene-di-ethyl-diamine or $N_2(C_6H_4.NEt_2)_2$ with EtI (Lippmann a. Fleissner, *B.* 16, 1427; *M.* 4, 301). Monoclinic plates (from dilute alcohol), $a:b:c = \cdot99:1:1\cdot833$; $\beta = 90°\ 30'$.—$B''H_2PtCl_6$.—$B''H_2Hg_4Cl_6$. Monoclinic prisms.—B''_2I_6: black prisms.—$B''2HI$.—$B''HI_3$.

PHENYLENE-ETHYL-BENZAMIDINE

$C_6H_4{<}\substack{NEt\\N}{>}CPh$. [81°]. Got by ethylation of phenylene-benzamidine (Howe, *Am.* 5, 421).—$B'HCl$ 3aq.—$B'_2H_2PtCl_6$.—$B'HNO_3$ aq [155°].—$B'EtOH$ [136°].—$B'EtI$ aq.—$B'EtCl$ 2aq.—$B'_2Et_2PtCl_6$. $B'EtHSO_4$ aq.

PHENYLENE-ETHYLENE-*o*-DIAMINE

$C_6H_4{<}\substack{NH.CH_2\\NH.CH_2}$. *Quinoxaline tetrahydride.* [97°]. (290°). V.D. 4·44 (calc. 4·64). Formed by heating pyrocatechin with ethylene-diamine hydrate at 200°–210° (Merz a. Ris, *B.* 20, 1191). Formed also by reducing quinoxaline with alcohol and Na. Plates (from water). $FeCl_3$ colours its dilute aqueous solutions blue or violet. Alkaline K_3FeCy_6 oxidises it to quinoxaline.—B''_23HCl. [above 150°]. Scales.—$B''_2H_2C_2O_4$. [184°].—$B''_32C_6H_3N_3O_7$. [above 120°]. Yellow crystalline pp., sl. sol. ether.

Acetyl derivative $C_6H_4:N_2Ac_2:C_2H_4$. [144°]. [350° uncor.). Granules, sl. sol. cold water.

Di-phenylene-ethylene-tetramine *v.* vol. ii. p. 491.

PHENYLENE-ETHYLENE-DISULPHONE $C_6H_4(SO_2)_2C_2H_4$. Formed by heating ethylene bromide with potassium benzene *m*-disulphinate

(Otto, *J. pr.* [2] 36, 450). White plates, m. sol. conc. HNO_3.

PHENYLENE DI-ETHYL DIKETONE $C_6H_4(CO.C_2H_5)_2$. [220°]. Formed from terephthalic chloride and $ZnEt_2$ in ether (Münchmeyer, *B.* 19, 1850). Needles (from ether).

PHENYLENE DI-ETHYL DISULPHONE $C_6H_4(SO_2Et)_2$. [142°]. Obtained by heating $C_6H_4(SO_2K)_2$ [1:4] with EtBr at 100° (Otto, *J. pr.* [2] 36, 449). Colourless plates.

PHENYLENE-FURFURALDEHYDINE *v.* vol. i. p. 109.

PHENYLENE-DIGLYCOLLIC ACID *v.* OXY-DIPHENYLENE-ACETIC ACID.

DIPHENYLENE-DIHYDRAZINE $C_{12}H_{14}N_4$ *i.e.* $N_2H_3.C_6H_4.C_6H_4.N_2H_3$. [167°]. Formed from benzidine hydrochloride by diazotisation and reduction by Na_2SO_3 or $SnCl_2$ (Arheidt, *A.* 239, 206). Small white plates, sol. hot water. Aqueous potassium cyanate forms the semicarbazide $C_{14}H_{16}N_6O_2$ [307°]. Nitrous acid forms a di-nitrosamine $C_{12}H_{12}N_4O_2$ [112°]. Pyruvic acid forms $C_{18}H_{14}N_4O_4$ [197°]. Acetone yields $C_{18}H_{22}N_4$ [198°], whence fusion with $ZnCl_2$ yields di-phenyl-di-methyl-indole $C_{18}H_{16}N_2$ [270°].

Reference.—DI-OXY-DI-PHENYLENE DIHYDRAZINE.

DIPHENYLENE-IMIDE *v.* CARBAZOLE.

DIPHENYLENE KETONE $\begin{matrix}C_6H_4\\C_6H_4\end{matrix}\!>\!CO$. [83°]. (above 300°).

Formation.—1. By distilling phenanthraquinone or diphenyl di-*o*-carboxylic acid with CaO (Fittig a. Ostermayer, *A.* 166, 373; Anschütz a. Schultz, *B.* 9, 1400).—2. By heating anthraquinone with lime (Anschütz, *B.* 11, 1213).—3. By dry distillation of the Ag salt of its dicarboxylic acid (Bamberger a. Hooker, *B.* 18, 1034; *A.* 229, 156).—4. By passing a mixture of phenol and CS_2 over hot copper (Carnelley a. Dunn, *C. J. Proc.* 4, 53; *B.* 21, 2005, who regard the product thus obtained as isomeride).

Properties.—Yellow needles or plates (from alcohol). Yields phenyl-benzoic acid by potash-fusion. Distillation over zinc-dust gives diphenylene-methane [113°] (Fittig, *B.* 6, 187). Forms a nitro- derivative [220°] and a di-nitro-derivative [290°] (Schultz, *A.* 203, 104). Alkaline $KMnO_4$ oxidises it to phthalic acid (Anschütz a. Japp, *B.* 11, 213). H_2SO_4 forms at 260° a disulphonic acid, whence CaA″ (Schmidt a. Schultz, *A.* 207, 345).

Oxim. [192°] (Spiegler, *M.* 5, 195).

References.—BROMO-, DI-CHLORO-, NITRO-, and OXY- DIPHENYLENE KETONE.

DIPHENYLENE KETONE CARBOXYLIC ACID [1:2] $C_6H_4\!<\!\overset{CO}{\underset{—}{}}\!>\!C_6H_3.CO_2H\left[\begin{smallmatrix}1\\2\end{smallmatrix}6\right]$. [192°]. Formed by oxidation of fluoranthene by chromic acid mixture (Fittig, *A.* 193, 149; 200, 6). Orange-red needles (from dilute alcohol).

Reactions.—1. *Potash-fusion* gives diphenyl *om*-dicarboxylic acid.—2. Yields diphenylene ketone on distillation.—3. Distillation with *zinc-dust* gives diphenylene-methane (fluorene).

Salts.—BaA'_2 4aq.—CaA'_2 2aq.—AgA′.

Diphenylene ketone carboxylic acid. [above 275°]. Formed by heating the dicarboxylic acid (Bamberger a. Hooker, *B.* 18, 1034; *A.* 229, 158). Pale yellow needles, sl. sol. alcohol. May be sublimed.—BaA'_2.—AgA′: yellow pp.

Diphenylene ketone carboxylic acid [1:2] $C_6H_4\!<\!\overset{CO}{\underset{—}{}}\!>\!C_6H_3.CO_2H\left[\begin{smallmatrix}1\\2\end{smallmatrix}3\right]$. [227° cor.].

Formation (Graebe, *B.* 13, 1303; *B.* 20 845; *A.* 247, 275).—1. From diphenyl di-*o*-carboxylic acid by heating with H_2SO_4 at 120° or with $POCl_3$ or $ZnCl_2$.—2. By heating diphenylene dicarboxylic acid with H_2SO_4 for 10 minutes at 150°.

Properties.—Yellow needles, v. sol. hot alcohol. Conc. H_2SO_4 forms a red solution.

Reactions.—1. *Potash-fusion* yields diphenyl di-*o*-carboxylic acid.—2. PCl_5 (1 mol.) forms $\begin{matrix}C_6H_4\\C_6H_3(COCl)\end{matrix}\!>\!CO$ [128°], which may be crystallised from ligroïn.—3. PCl_5 (2 pts.) at 160° yields $\begin{matrix}C_6H_4\\C_6H_3(COCl)\end{matrix}\!>\!CCl_2$ [95°], which yields fluorene carboxylic acid on reduction with zinc-dust and dilute acetic acid.—4. *Zinc-dust* and *ammonia* reduce it to $\begin{matrix}C_6H_4\\C_6H_3(CO_2H)\end{matrix}\!>\!CH(OH)$.—5. HI and P give fluorene.—6. *Phenol* and $SnCl_4$ at 120° give $\begin{matrix}C_6H_4\\C_6H_3(CO_2H)\end{matrix}\!>\!C(C_6H_4.OH)_2$ [165°], which yields AgA′ and $C_{26}H_{16}Ac_2O_4$ [c. 130°].—7. *Resorcin* gives rise, on heating, to $\begin{matrix}C_6H_4\\C_6H_3(CO_2H)\end{matrix}\!>\!C(C_6H_3(OH)_2)_2$, a yellowish-brown powder which exhibits green fluorescence in alkaline solutions.

Salts. — NH_4A' aq. — NaA′ 6aq: yellow needles, v. sol. hot water.—AgA′: yellow pp.

Methyl ether MeA′. [132°]. Needles.

Ethyl ether EtA′. [103°]. Needles.

Chloride $C_{14}H_7ClO_2$. [128°].

Amide $C_{14}H_7(NH_2)O_2$. [225°]. Silky yellow needles (containing ½HOEt). Formed from the chloride, and also by heating phenanthraquinone mono-oxim with H_2SO_4 at 100° (Wegerhoff, *B.* 21, 2357).

Oxim $C_{14}H_7(CO_2H)(C:NOH)$. [263°].

Phenyl-hydrazide $C_{14}H_7(CO_2H)(C:N_2HPh)$. [205°]. Brownish-yellow prisms, m. sol. alcohol.

Diphenylene ketone dicarboxylic acid $C_6H_4\!<\!\overset{CO}{\underset{—}{}}\!>\!C_6H_2(CO_2H)_2\left[\begin{smallmatrix}1\\2\end{smallmatrix}3:6\right]$. Formed by oxidation of retene-quinone and of oxyisopropyl-diphenylene-ketone carboxylic acid (Bamberger a. Hooker, *B.* 18, 1033; *A.* 229, 151). Yellow needles (from HOAc). Not melted at 270°, but loses CO_2 at a higher temperature. Yields diphenyl on heating with CaO. Potash-fusion forms diphenyl tricarboxylic acid.—BaA″.—Ag_2A'': yellow pp.

Methyl ether Me_2A''. [184°]. Yellow needles.

Ethyl ether EtA″. [115°]. Needles.

Oxim $C_{12}H_6(CO_2H)_2{:}C(NOH)$. Yellow pp., not melted at 280°.

DIPHENYLENE KETONE OXIDE $CO\!<\!\begin{matrix}C_6H_4\\C_6H_4\end{matrix}\!>\!O$. *Xanthone.* [174°]. (350°) at 730 mm. (Graebe, *A.* 254, 280). S. (alcohol) ·7 in the cold; 8·5 at 78°.

Formation.—1. Obtained by oxidation of $CH_2\!<\!\begin{matrix}C_6H_4\\C_6H_4\end{matrix}\!>\!O$ with CrO_3 and HOAc (Merz a.

Weith, *B.* 14, 192).—2. By the dry distillation of salicylide; the yield being 35 p.c. of the theoretical (Perkin, *B.* 16, 339).—3. By distilling phenyl phosphate with sodium *m*- or *p*-oxy-benzoate (Richter).—4. By the action of $POCl_3$ on potassium-salicylate of ethyl.—5. By distilling neutral or basic sodium salicylate with P_2O_5.—6. In small quantities, when salicylic acid is distilled.—7. By strongly heating sodium *o*-chlorobenzoate.—8. From sodium *o*-phenyl-benzoate and $POCl_3$.—9. To the amount of 12 p.c. of the theoretical quantity, by the action of *o*-chlorobenzoyl chloride on basic sodium salicylate.—10. By the action of conc. H_2SO_4 on [1:2] $C_6H_4(OPh).CO_2H$ (Graebe, *B.* 21, 503).—11. By distilling phenyl salicylate (Seiffert, *J. pr.* [2] 31, 479).—12. By heating salicylic acid (1 mol.) with PCl_5 (1 mol.), then adding phenol and distilling (Klepl, *J. pr.* [2] 28, 217.—13. By distilling calcium *p*-oxy-benzoate (Goldschmidt, *M.* 4, 128).—14. A product of the electrolysis of a solution of phenol in KOHAq at 200° (Bamberger a. Berlé, *B.* 24, 3212).

Preparation.—1. Phenyl phosphate (20 g.) and sodic salicylate (20 g.) are distilled together; a violent action ensues; when it is over the residue is distilled over at 400°, best in a current of air. The crude product is shaken with solution of NaOH and distilled with steam. The residue is extracted with alcohol, from which, on cooling, the ketone crystallises (R. Richter, *J. pr.* [2] 28, 276).—2. By distilling salicylic acid with Ac_2O, the salicylide which is first formed splitting off CO_2 when the temperature rises (Perkin, *C. J.* 43, 35). In this process there is formed a by-product $C_{14}H_8O_3$ [192°] which is converted by boiling alcoholic potash into an acid $C_{14}H_8O_4$ [275°] (A. G. Perkin, *C. J.* 43, 187).

Properties.—Long white needles, grouped concentrically. M. sol. ether, alcohol and benzoline, more sol. benzene and chloroform, insol. water. The solution in conc. H_2SO_4 shows blue fluorescence (Graebe, *B.* 15, 1679). Does not react with hydroxylamine or phenyl-hydrazine (Spiegler, *B.* 17, 808).

Reactions.—1. Reduced by *zinc*-dust or by HI to $CH_2{<}\substack{C_6H_4\\C_6H_4}{>}O$ [100·5°] but no further.—2. *Potash-fusion* converts it into salicylic acid and phenol.—3. If the fusion be stopped when the mass is pasty (at about 200°), dissolved in water and ppd. by HCl, di-oxy-benzophenone is obtained, $CO(C_6H_4OH)_2$.—4. *Sodium-amalgam* reduces the di-phenylene-ketone oxide (in dilute alcoholic solution) to $C_{26}H_{18}O_3$ [200°]. This body crystallises from $CHCl_3$ in prisms. It is split up by chromic acid into di-phenylene-ketone oxide and diphenylene methane oxide, so that it is perhaps a molecular compound of these two bodies.—5. *Bromine* at 200° forms a di-bromo- derivative [212°].—6. Fuming H_2SO_4 gives a disulphonic acid which forms BaA″ aq, crystallising from hot water in needles (A. G. Perkin, *C. J.* 43, 192).

Isomeride $C_{13}H_8O_2$. [91°] (R.); [96°] (G.). A product of the action of $POCl_3$ on sodium salicylate (Richter, *J. pr.* [2] 28, 294). Formed also by heating the sulphate of *o*-diazobenzoic acid with phenol (Griess, *B.* 21, 981). Needles, v. e. sol. ether. Yields diphenyl on distillation with zinc-dust. Br gives $C_{13}H_7BrO_2$ [193°]. H_2SO_4 yields a disulphonic acid, which gives BaA″aq crystallising in needles.

Dixanthone  $C_6H_4{<}\substack{O\\CO}{>}C_6H_2{<}\substack{O\\CO}{>}C_6H_4$. [256°]. Occurs in the product of the action of salicylic acid on resorcin (Kostanecki a. Seidmann, *B.* 25, 1654). It crystallises from HOAc in groups of needles, and its solution in H_2SO_4 shows greenish fluorescence.

References. — Di-amido-, Nitro-, and Oxy-diphenylene ketone oxide.

PHENYLENE MERCAPTAN *v.* Di-thio-resorcin and Di-thio-hydroquinone.

Diphenylene mercaptan $C_6H_4(SH).C_6H_4(SH)$. [176°]. Formed by diazotising benzidine, and treating the product with potassium xanthate and alcoholic potash successively (Leuckart, *J. pr.* [2] 41, 212; *cf.* Gabriel, *B.* 13, 390). White plates (from alcohol).

Di-methyl ether Me_2A''. [184°]. Plates.

Di-ethyl ether Et_2A''. [135°]. Plates.

oo-**DIPHENYLENE-METHANE** *v.* Fluorene.

(γ) - Diphenylene - methane  $CH_2{<}\substack{C_6H_4\\C_6H_4}$. *Methylene-diphenyl.* [118°]. (295° uncor.). V.D. 84 (calc. 83). Occurs, together with the (δ)-isomeride, among the products of the passage of a mixture of benzene and toluene through a red-hot tube (Carnelley, *C. J.* 37, 708). Pearly plates (from alcohol), sl. sol. cold alcohol, v. sol. ether. Its alcoholic solution shows faint blue fluorescence. CrO_3 and HOAc oxidise it to $C_{13}H_8O_2$ [281° cor.]. Bromine in ether gives $C_{13}H_8Br_2$ [162°]. Picric acid forms a compound $C_{13}H_{10}C_6H_3N_3O_7$ crystallising in blood-red needles [81°].

(δ)-Diphenylene-methane $C_{13}H_{10}$. [205°]. (320°). V.D. 86·2 (calc. 83). Formed as above. Pearly plates (from alcohol). Oxidised by CrO_3 in HOAc to $C_{13}H_8O_2$ [288° cor.] which sublimes in white needles.

DIPHENYLENE-METHANE OXIDE  $CH_2{<}\substack{C_6H_4\\C_6H_4}{>}O$. [100°]. (315° cor.). Formed, to the amount of 2 p.c., in the preparation of Ph_2O by heating phenol with $AlCl_3$ (Merz a. Weith, *B.* 14, 191). Formed also from diphenylene ketone oxide by heating with fuming HIAq at 160° or by distilling with zinc-dust (R. Richter, *J. pr.* [2] 28, 280; Graebe, *A.* 254, 282); and by distilling euxanthone over heated zinc-dust (Wichelhaus a. Salzmann, *B.* 10, 1399; Graebe a. Ebrard, *B.* 15, 1678). White plates (from alcohol).

Reactions.—1. Oxidised by CrO_3 or dilute HNO_3 to diphenylene ketone oxide.—2. PCl_5 forms HCl and a product whence water at 0° produces $C_{13}H_9O.PO(OH)_2$ [255°-260°] an acid forming Ag_2A'' and $(NH_4)_2A''$.—3. Br forms $C_{13}H_4Br_6O$ and $C_{13}H_3Br_7O$ [136°].

DIPHENYLENE - METHANE SULPHIDE  $CH_2{<}\substack{C_6H_4\\C_6H_4}{>}S$. [128°]. (342°). Formed by reducing $CO{<}\substack{C_6H_4\\C_6H_4}{>}S$ with HI and P at 170°; and also by passing phenyltolyl sulphide through a red-hot tube (Graebe a. Schultess, *A.* 263, 12). Needles, sl. sol. cold alcohol, v. e. sol. $CHCl_3$.

DIPHENYLENE - METHANE SULPHONE  $CH_2{<}\substack{C_6H_4\\C_6H_4}{>}SO_2$. [170°]. Formed by heating  $CO{<}\substack{C_6H_4\\C_6H_4}{>}SO_2$ with HI and P at 170° (Graebe a. Schultess, *A.* 263, 15). Needles, v. sol. hot alcohol.

PHENYLENE-METHENYL-AMIDINE $C_6H_4{<}\substack{NH\\N}{\geqslant}CH$. [167°]. (above 360°). Formed by boiling phenylene-*o*-diamine with formic acid (Wundt, *B.* 11, 826; Fischer, *B.* 22, 645). Trimetric crystals (from alcohol).—B'HCl aq.—B'HAuCl$_4$. Yields on methylation $C_8H_8N_2$ [33°] (278° at 730 mm.).

Carboxylic acid  $CO_2H.C_6H_3{<}\substack{NH\\N}{\geqslant}CH$. Formed by reducing the formyl derivative of (2,1,4)-nitro-amido-benzoic acid (Zehra, *B.* 23, 3634). White needles, blackening without fusion when heated.—HA'HCl: white needles.

***m*-PHENYLENE - METHYL - DIAMINE** [1:3] $C_6H_4(NH_2).NHMe$. *Methyl-phenylene diamine. Amido-methyl-aniline* (265°-270° uncor.). Formed by reduction of *m*-nitro-methyl-aniline (Nölting a. Stricker, *B.* 19, 548). Oil. Gives a methyl-chrysoïdine with diazobenzene chloride.

***p*-Phenylene-methyl-diamine** [1:4] $C_6H_4(NH_2)(NHMe)$. (258° uncor.). Formed by reduction of *p*-nitroso-methyl-aniline (Fischer, *B.* 19, 2992) or of $C_6H_4(NHMe).N_2.C_6H_4.SO_3H$ (Bernthsen a. Goske, *B.* 20, 929). Oil, v. sol. water. $FeCl_3$ gives a red colour, which on successive treatment with HCl and H_2S becomes blue (dimethylthionine).—$B'_2H_2SO_4$: white needles (from water).

***m*-Phenylene-di-methyl-diamine** [1:3] $C_6H_4(NH_2)(NMe_2)$. (269°) at 740 mm. S.G. ^{25} ·995 (Groll, *B.* 19, 200); (258°) (Staedel a. Bauer, *B.* 19, 1945). Formed by reduction of *m*-nitro-di-methyl-aniline. Oil. With nitrous acid it yields a colouring-matter closely resembling Bismarck brown. With diazobenzene chloride it yields a di-methyl-chrysoïdine which dies a somewhat redder shade than chrysoïdine. PbO_2 and aqueous HOAc gives a yellowish-brown colour (Lauth, *C. R.* 111, 975).—B'HCl.

Acetyl derivative $C_6H_4(NMe_2)(NHAc)$. [87°].

***p*-Phenylene-di-methyl-diamine** [1:4] $C_6H_4(NH_2)(NMe_2)$. [41°]. (257° i.V.). Prepared by reduction of nitroso-di-methyl aniline and of $(C_6H_4NMe_2)_2N_2O$ by tin and HCl (Schraube, *B.* 8, 616; Wurster, *B.* 12, 522; Weber, *B.* 10, 760). Prepared also by reduction of $C_6H_4(NMe_2).N_2.C_6H_4.SO_3H$ (E. Fischer, *B.* 16, 2255). Formed also together with di-chloro-*p*-phenylene-diamine and di-chloro-*p*-phenylene-di-methyl diamine by boiling nitroso-di-methyl-aniline with HCl (S.G. 1·2) (Möhlau, *B.* 19, 2010).

Properties.—Long white needles or short prisms, v. sol. water, alcohol, and ether. PbO_2 and aqueous HOAc give a magenta-red solution changing to violet-black (Lauth, *C. R.* 111, 975). Colours wood, and paper made from wood, crimson (Wurster, *B.* 20, 808).

Reactions.—1. Yields quinone on oxidation with MnO_2 and H_2SO_4.—2. *Bromine* in HOAc forms $C_8H_{11}N_2Br$, which crystallises from its red alcoholic solution in green scales [146°] (Wurster a. Sendtner, *B.* 12, 1803).—3. H_2S and an oxidising agent (*e.g.* $FeCl_3$) gives methylene-blue (*v.* vol. iii. p. 265). Methylene-red  $S_2{<}\substack{C_6H_3\\N\,—}{>}NMe_2Cl$ is a by-product (Bernthsen, *A.* 230, 137; 251, 1).—4. $Na_2S_2O_3$ and CrO_3 give $C_6H_3(NMe_2)(NH_2)S.SO_3H$, which yields methylene-blue on further oxidation.—5. *Aldehydes* and *ketones* form products of condensation, *e.g.* $C_6H_4(NMe_2).N{:}CHPh$ [93°] (Calm, *B.* 17, 2938), $C_6H_4(NMe_2).N{:}CH.C_6H_4OH$ [1:2] [134°], and $C_6H_4(NMe_2).N{:}CH.C_6H_4.OMe$ [1:4] [148°] (Nuth, *B.* 18, 574; Steinhart, *A.* 241, 343). Benzil and alcoholic KOH form $CPhBz{:}N.C_6H_4NMe_2$ [139°]; benzoyl-acetone forms in like manner $CH_2Bz.CMe{:}N.C_6H_4NMe_2$ [136°] (Vogtherr, *B.* 25, 635). Benzoïn gives $CHPh(OH).CPh{:}N.C_6H_4NMe_2$ [127°] on heating, while deoxybenzoïn forms $C_{22}H_{22}N_2$ [139°].—6. *Oxalic ether* forms, on heating, the ether $C_6H_4(NMe_2).NH.CO.CO_2Et$ [117°] which yields a corresponding acid [192°] and amide [259°] (Sendtner, *B.* 12, 530).

Salts.—B''2HCl. Very deliquescent plates.—$B''H_2SnCl_4$. Cubes.—$B''H_2PtCl_6$.

Acetyl derivative $C_6H_4(NMe_2)(NHAc)$. [130°]. (355°). Small leaflets or needles.

***p*-Phenylene-tri-methyl-diamine** [1:4] $C_6H_4(NMe_2)(NMeH)$. (265°). Obtained by reduction of its nitrosamine, which is formed by the action of nitrous acid on *p*-phenylene-tetra-methyl-diamine (Wurster a. Schobig, *B.* 12, 1809). Oil.

Acetyl derivative. [95°]. Prisms.

Nitrosamine $C_6H_4(NMe_2)(NMe.NO)$. [99°]. Leaflets or tables, sl. sol. cold water.

***m*-Phenylene-tetra-methyl-diamine** [1:3] $C_6H_4(NMe_2)_2$. [−2°]. (266° i.V.). S.G. ^{15} ·992. Prepared by heating phenylene-*m*-diamine with methyl alcohol and HCl at 190° (Wurster a. Morley, *B.* 12, 1814). Purified by distilling with Ac_2O (Romburgh, *R. T. C.* 7, 2). Oil, sl. sol. water. HOAc and nitric acid give $C_6H(NO_2)_3N_2Me_3NO$ [132°]. *s*-Tri-nitro-benzene forms $B''C_6H_3(NO_2)_3$ [121°]. *m*-Di-nitro-benzene gives $B''C_6H_4(NO_2)_2$ [58°] crystallising in needles. Bromine forms oily $C_{10}H_{14}Br_2N_2$. $NaNO_2$ and dilute HClAq give oily $C_6H_3(NO)(NMe_2)_2$, which forms a hydrochloride B'HCl, crystallising in dark-red needles (Witt, *B.* 18, 877).

Salts.—$B''H_2Cl_2$ 2aq: hygroscopic crystals.—$B''H_4FeCy_6$ aq. Pearly plates (Wurster a. Roser, *B.* 12, 1826).

Methyl iodide B''MeI. [192°]. Crystals, v. sol. water.—$B''MeHI_2$.

Di-methylo-di-iodide $B''Me_2I_2$. Plates, v. sol. water (Hofmann, *Pr.* 12, 639).

***p*-Phenylene-tetra-methyl-diamine** [1:4] $C_6H_4(NMe_2)_2$. [51°]. (260° i.V.). Prepared by heating *p*-phenylene-di-methyl-diamine with MeOH and HClAq at 200° (Wurster, *B.* 12, 526, 1803, 1827). White leaflets, sl. sol. cold water, v. sol. alcohol. Its aqueous solution becomes violet-blue on exposure to air or addition of oxidising agents. The blue substance appears only to exist as a salt, *e.g.*  $C_6H_4{<}\substack{NMe_2Cl\\NMe\,—}{>}CH_2$ (Wurster, *B.* 19, 3195; 20, 256; 21, 921). It becomes colourless on further oxidation.

Reactions.—1. *Bromine* in HOAc forms a blue colouring matter $C_{10}H_{14}N_2$, which forms blue solutions in water and alcohol.—2. K_3FeCy_6 added to a solution of the sulphate forms $C_{10}H_{14}N_2 2H_4FeCy_6$ crystallising in lustrous blue needles. — 3. Sodium nitrite and hydrochloric acid give $C_6H_4(NMe_2)(NMeNO)$ [98°] and *$C_6H_3(NO_2)(NMe_2).NMe.NO$ [87°].*

Salts.—B''2HCl; crystals.—B''H_2PtCl_6.—B''$2H_2SO_4$.—B''H_4FeCy_6: white needles.

Methylo-iodides B''MeI. [above 270°]. Leaflets (W.).—B''Me_2I_2. Plates (Hofmann).

Reference.—NITRO-PHENYLENE-DI-METHYL-DI-AMINE.

PHENYLENE - DI - METHYL - DI - AMINE SULPHONIC ACID $C_6H_3(NH_2)(NMe_2).SO_3H$. Got by reduction of *p*-nitro-di-methyl-amido-benzene sulphonic acid (Michler a. Walder, *B.* 14, 2176). Large rhombohedra, v. sol. water.—BaA'_2.—CaA'_2: plates.

***p*-PHENYLENE-DI-METHYL-DI-ETHYL-DIAMINE** $C_6H_4(NMe_2)(NEt_2)$. (264°). Formed from [1:4] $C_6H_4(NEt_2)(NH_2)$, MeOH, and HClAq at 200° (Lippmann a. Fleissner, *M.* 4, 791). Liquid. Coloured blue by oxidising agents.

Methylo-iodide B''2MeI. [218°]. Yields B''Me_2PtCl_6, B''Me_2AuCl_8, B''Me_2CdI_4, and B''$Me_2(C_6H_2N_3O_7)_2$ [235°].

***o*-PHENYLENE - METHYL - ETHYLENE - DIAMINE** $C_6H_4{<}\begin{matrix}NMe\\NH\end{matrix}{>}C_2H_4$. *v-Methyl-quinoxaline tetrahydride.* (274°). Formed by heating phenylene-ethylene-diamine with MeI at 110° (Ris, *B.* 21, 381). Liquid. Its aqueous solution is coloured blue by $FeCl_3$.

Methylo-iodide B'MeI. [above 200°]. Crystals.—$B'_2Me_2PtCl_6$. Yellow needles.

DIPHENYLENE - METHYL - FURFURANE $\begin{matrix}C_6H_4.C—CH\\C_6H_4.C.O.CMe\end{matrix}$. [124°]. Got by reducing $\begin{matrix}C_6H_4.C(OH).CH_2Ac\\C_6H_4.CO\end{matrix}$ (Japp a. Klingemann, *B.* 21, 2932).

PHENYLENE-DI-METHYL-DI-MALONIC ACIDS $C_6H_4(CH_2.CH(CO_2H)_2)_2$. The ethers of these acids are formed by the action of zinc-dust on the acids $C_6H_4(CH_2.CCl(CO_2Et)_2)_2$ which are formed from sodium chloro-malonic ether and ω-di-bromo-xylenes (Perkin a. Kipping, *C. J.* 53, 16; *B.* 19, 437; 21, 36). The *o*- and *m*- ethers are oily, the *p*- ether is crystalline [51°]. The ethers form deliquescent sodium derivatives $Na_2C_{22}H_{28}O_8$, and the *o*- compound of this formula is converted by iodine into the tetrahydride of naphthalene tetracarboxylic ether. The *m*- acid is a liquid v. sol. water, the *p*- acid is crystalline [195°]. The *p*- acid forms Ag_4A'', and when heated splits up into CO_2 and $C_6H_4(CH_2.CH_2.CO_2H)_2$ [223°].

PHENYLENE - METHYL - METHENYL - AMIDINE $C_6H_4{<}\begin{matrix}NMe\\N\end{matrix}{\gg}CH$. [33°]. (278°) at 780 mm. Formed from phenylene-methenyl-amidine, MeI, and MeOH at 100° (O. Fischer, *B.* 22, 644). Prisms.—B'$HAuCl_4$. Needles.

DIPHENYLENE-METHYL-PYRAZINE $\begin{matrix}C_6H_4.C.N:CMe\\C_6H_4.C.N:CH\end{matrix}$. [128°]. Formed from phenanthraquinone and propylene-diamine (Strache, *B.* 21, 2362). White needles.—$B'_2H_2PtCl_6$.

***v-p*-DIPHENYLENE-TETRA-METHYL-DI-PYRROLE** $C_{24}H_{24}N_2$ *i.e.* $\begin{matrix}CH:CMe\\CH:CMe\end{matrix}{>}N.C_6H_4.C_6H_4.N{<}\begin{matrix}CMe:CH\\CMe:CH\end{matrix}$. [150°]. Got by heating an alcoholic solution of acetonyl-acetone (2 mols.) and benzidine (1 mol.) (Paal a. Schneider, *B.* 19, 3158). Colourless tables. *Sol. alcohol, ether, benzene, and ligroïn.*

DIPHENYLENE-METHYL-QUINOXALINE $C_{21}H_{14}N_2$ *i.e.* $C_6H_3Me{<}\begin{matrix}N:C.C_6H_4\\N:C.C_6H_4\end{matrix}$. [213°]. Formed from (1,3,4)-tolylene-diamine and phenanthraquinone in HOAc (Hinsberg, *B.* 17, 323). Yellow hair-like crystals, v. sol. benzene.

DIPHENYLENE - NAPHTHOQUINOXALINE $C_{10}H_6{<}\begin{matrix}N:C.C_6H_4\\N:C.C_6H_4\end{matrix}$. [273°]. Formed by boiling an alcoholic solution of (1,2)-naphthylene-diamine with phenanthraquinone in HOAc (Lawson, *B.* 18, 2426). Small yellow crystals.

The **sulphonic acid**, got by mixing a hot aqueous solution of naphthylene-*o*-diamine sulphonic acid with phenanthraquinone dissolved in $NaHSO_3Aq$ with addition of NaOAc, forms a yellow crystalline Na salt, sol. hot water, but ppd. by alkalis (Witt, *B.* 19, 1719, 2791). When fused with KOH it yields the insoluble eurhodol $C_{12}H_8{<}\begin{matrix}N\\N\end{matrix}{>}C_{10}H_5(OH)\left[\begin{matrix}1&4\\2&\end{matrix}\right]$, which forms a scarlet hydrochloride.

***m* - PHENYLENE - DI - (β) - NAPHTHYL - DIAMINE** $C_6H_4(NHC_{10}H_7)_2$. [126°]. Formed by heating *m*-phenylene-diamine with (β)-naphthol (Ruhemann, *B.* 14, 2654). Felted needles, sol. alcohol and ether.

***p*-Phenylene-di-(β)-naphthyl-diamine** $C_6H_4(NHC_{10}H_7)_2$. [235°]. (over 400° *in vacuo*). Formed by heating *p*-phenylene-diamine with (β)-naphthol at 200° (Ruell, *B.* 22, 1080). White plates, almost insol. boiling alcohol, v. sol. nitro-benzene. KNO_2 added to its solution in conc. H_2SO_4 gives a greenish-violet colour, changing to blue.—$B'2C_6H_3N_3O_7$. [c. 217°].

Acetyl derivative $C_6H_4(NAc.C_{10}H_7)_2$. [210°]. Plates (from benzene).

Benzoyl derivative $C_{26}H_{18}Bz_2N_2$. [220°].

Reference.—NITRO-PHENYLENE-NAPHTHYL-DI-AMINE.

PHENYLENE - NAPHTHYLENE - AMINE $C_{16}H_{11}N$ *i.e.* $\begin{matrix}[1:2]\ C_6H_4\\ [2:3]\ C_{10}H_6\end{matrix}{>}NH$. *Phenyl-naphthyl-carbazole.* [330°]. (454°) (Schweizer, *A.* 264, 195). S. (alcohol) ·25 at 78°; S. (toluene) ·5 at 111° (Bechi, *B.* 12, 1978). Occurs in crude anthracene, from which it may be got from the residues after sublimation of the anthracene (Graebe a. Knecht, *B.* 12, 341, 2242; *A.* 202, 1). Formed by passing phenyl-(β)-naphthyl-amine through a red-hot tube. Colourless plates, v. sl. sol. HOAc. Its solutions show blue fluorescence. Oxidation by $K_2Cr_2O_7$ and H_2SO_4 forms the quinone $\begin{matrix}C_6H_4—\\C_{10}H_4O_2\end{matrix}{>}NH$ [307°] which crystallises from HOAc in reddish-yellow needles, and is accompanied by $\begin{matrix}C_6H_4—\\C_{10}H_4O_2\end{matrix}{>}O$ which crystallises from benzene in red prisms.

Acetyl derivative $C_{18}H_{13}NO$. [121°].

Nitrosamine $C_{16}H_{10}N_2O$. [210°].

Tetrahydride $C_{16}H_{15}N$. Formed by reduction with HIAq and P at 210°. Syrup.—B'HI. Long needles.

Phenylene-naphthylene-amine
$\begin{matrix}[1{:}2]\,C_6H_4\\ [2{:}1]\,C_{10}H_6\end{matrix}\!\!>NH$. [225°]. Formed by heating
$S\!\!<\!\!\begin{matrix}C_6H_4\\ C_{10}H_6\end{matrix}\!\!>NH$ with reduced copper at 240° (Kym, *B.* 23, 2465). Greenish-yellow plates, sl. sol. cold benzene, v. sol. hot alcohol.

PHENYLENE - NAPHTHYLENE - KETONE OXIDE
$CO\!\!<\!\!\begin{matrix}C_{10}H_5\\ C_6H_4\end{matrix}\!\!>O$. [155°]. Formed by boiling (*a*)-naphthyl salicylate (Graebe a. Feer, *B.* 19, 2612). Formed also by heating (*a*)-naphthol with salicylic acid and HOAc; and by distilling (1,2)-(*a*)-naphthol carboxylic acid with salicylic acid (Kostanecki, *B.* 25, 1643). Crystals, sl. sol. cold alcohol. Its solution in H_2SO_4 shows green fluorescence. Converted by potash-fusion into *o*-(*a*)-di-oxy-phenyl-naphthyl-ketone (Phomina, *A.* 257, 92).

Isomeride. [140°]. Formed in like manner from (*β*)-naphthyl salicylate; and by heating (2,1)-(*β*)-naphthol carboxylic acid with salicylic acid. Needles. Reduced by zinc-dust to
$CH_2\!\!<\!\!\begin{matrix}C_{10}H_6\\ C_6H_4\end{matrix}\!\!>O$. [80°].

p-**PHENYLENE-DI-(β)-NAPHTHYL-DI-METHYL-DIAMINE** $C_6H_4(NMe.C_{10}H_7)_2$. [180°]. Formed from $C_6H_4(NHC_{10}H_7)_2$, MeI, and MeOH at 140° (Rueff, *B.* 22, 1080). Plates.

PHENYLENE - NAPHTHYLENE OXIDE
$\begin{matrix}C_6H_4\\ C_{10}H_6\end{matrix}\!\!>O$. [178°]. Formed by distilling a mixture of phenol and (*a*)-naphthol with PbO (Arx, *B.* 13, 1726; *A.* 209, 141). Yellow needles, sl. sol. alcohol. H_2SO_4 forms a tetrasulphonic acid which gives $Ba_2C_{16}H_6S_4O_{13}$ 4aq. CrO_3 and HOAc form $C_{16}H_8O_3$ [140°].—$C_{16}H_{10}O2C_6H_3N_3O_7$. [165°].

Isomeride $C_{16}H_{10}O$. [296°] (A.); [300°] (G. a. K.). Formed in like manner from (*β*)-naphthol (A.). Got also by distilling the compound $C_{16}H_8O_3$ (from phenylene-naphthylene-amine) with zinc-dust (Graebe a. Knecht, *A.* 202, 15). Plates, v. sol. toluene.

References.—DI-BROMO-, DI-CHLORO-, and DI-NITRO- PHENYLENE-NAPHTHYLENE OXIDE.

PHENYLENE OXIDE C_6H_4O? [103°]. A product of the distillation of *o*-oxy-benzoyl-*o*-oxy-benzoic acid (Märker, *A.* 124, 249). Silky needles (from alcohol). HNO_3 yields the nitro-compound $C_6H_3(NO_2)O$ [150°].

Diphenylene oxide $C_{12}H_8O$ *i.e.*
$\begin{matrix}C_6H_4\\ C_6H_4\end{matrix}\!\!>O$. [87°]. (283°) (Galewsky, *A.* 264, 188).

Formation.—1. By distilling Ph_3PO_4 over lime, MgO, or PbO (Lesimple, *A.* 138, 375; Hoffmeister, *Z.* [2] 7, 24; *A.* 159, 211; Kreysler, *B.* 18, 1720).—2. By distilling phenol (2 pts.) with PbO (3 pts.) (Behr a. Dorp, *B.* 7, 398; Graebe, *A.* 174, 190).—3. By distilling $Ca(OPh)_2$ (Niederhäusern, *B.* 15, 1120).—4. By the action of red-hot lime on di-phenylene-ketone oxide.—5. One of the products of the action of HCl on mucic acid at 150°.

Properties.—White plates (from alcohol). Converted by AcCl into
$\begin{matrix}CH_3.CO.C_6H_3\\ C_6H_4\end{matrix}\!\!>O$ [81°], which yields an oxim [146°] and a phenyl-hydrazide [133°]. H_2SO_4 forms a deliquescent disulphonic acid, which yields $BaC_{12}H_6S_2O_7$ aq.

Picric acid compound $C_{12}H_8OC_6H_3N_3O_7$. [24°]. Yellow crystals (Goldschmiedt a. Schmidt, *M.* 2, 14).

References.—AMIDO-, BROMO-, TETRA-CHLORO-, DI-IODO, DINITRO- PHENYLENE OXIDES.

o-**PHENYLENE - OXY - BENZAMIDINE**
$C_6H_4\!\!<\!\!\begin{matrix}NH\\ N\end{matrix}\!\!\gg C.C_6H_4.OH$. [223°]. Formed by reducing salicyl-*o*-nitro-aniline with tin and HCl (Mensching, *A.* 210, 345). Needles.—B'HCl aq.—$B'_2H_2SO_4$ 4aq. Needles, sl. sol. Aq.

o-**PHENYLENE-PHENYL-DIAMINE.** The *sulphonic acid* which gives the barium salt BaA'_2 2aq may be got from its anilide [1:2:4] $C_6H_3(NHPh)(NH_2).SO_2NHPh$ [157°] which is got by reduction of $C_6H_3(NHPh)(NO_2).SO_2NHPh$, and yields B'HCl [182°] (Fischer, *B.* 24, 3794).

p-**Phenylene-phenyl-diamine** $C_6H_4(NHPh).NH_2$. *Amido-diphenylamine.* [67°] and [75°]. (354°).

Formation.—1. By reduction of nitro-diphenylamine (Nietzki a. Witt, *B.* 12, 1401). 2. From *p*-nitroso-diphenylamine by boiling with alcoholic potash, by reduction with tin and HCl (Ikuta, *A.* 243, 279), or by treatment with phenyl-hydrazine in ether (O. Fischer, *B.* 21, 2615).—3. Together with azophenine, by heating *p*-nitroso-diphenylamine with aniline and aniline hydrochloride (O. Fischer a. Hepp, *B.* 20, 2480). 4. By reducing $C_6H_4(NHPh)N_2C_6H_4SO_3Na$ (Hess a. Bernthsen, *B.* 18, 692).

Properties.—Plates or needles, sl. sol. water, v. sol. alcohol. Melts at 75° after crystallisation from ligroïn. $FeCl_3$ added to a solution of its salts gives a red colour, turned green by excess. Yields quinone on oxidation.

Salt.—$B'_2H_2SO_4$. Plates.

Nitrosamine $C_{18}H_{14}N_4O_2$. [c. 130°].

Acetyl derivative $C_{14}H_{14}N_2O$. [158°].

Benzoyl derivative (Lellmann, *B.* 15, 826).

Sulphonic acid. [1:4:2] $C_6H_3(NHPh)(NH_2).SO_3H$. Formed by reducing $C_6H_3(NHPh)(NO_2).SO_3H$ (Fischer, *B.* 24, 3800). Yields BaA'_2 aq and an anilide [171°], which gives B'HCl [215°].

m-**Phenylene-di-phenyl-diamine** $C_6H_4(NHPh)_2$. [95°]. Formed by heating resorcin (2 mols.) with aniline (8 mols.), $CaCl_2$ (8 mols.) and $ZnCl_2$ (1 mol.) for 35 hours at 210° (Calm, *B.* 16, 2792). Flat needles, v. sol. ether. Oxidising agents give a green colour passing to bluish violet. Amyl nitrite and alcohol HCl form the *p*-nitroso- derivative $C_{18}H_{15}N_3O$, crystallising in brown-red prisms and yielding B''2HCl (Fischer a. Hepp, *A.* 255, 145). B''2HCl: needles decomposed by water.

Acetyl derivative $C_6H_4(NPhAc)_2$. [163°].

Benzoyl derivative $C_6H_4(NPhBz)_2$. [184°].

Nitrosamine $C_6H_4(NPh.NO)_2$. [102°]. Yellow needles, forming a violet solution in H_2SO_4.

p-**Phenylene-di-phenyl-diamine** $C_6H_4(NHPh)_2$. [132°] (Bandrowski, *M.* 8, 475); [141°] (Limpricht, *B.* 22, 2910); [145°] (O. Fischer, *B.* 21, 2615); [152°] (Calm, *B.* 16, 2803). Formed by heating hydroquinone (5 pts.) with aniline (17 pts.), $CaCl_2$ (20 g.), and $ZnCl_2$ (5 g.) for 18 hours at 210°. Formed also by the action of phenyl-hydrazine on nitroso-diphenyl-

amine in alcohol, and from the hydrochloride of amido-salicylic acid and aniline. Plates, v. sol. hot benzene. HNO_3 added to its solution in H_2SO_4 gives a blue liquid, changing to red.—B″2HCl: needles, decomposed by water.

Acetyl derivative $C_6H_4(NPhAc)_2$. [192°].

Benzoyl derivative $C_6H_4(NPhBz)_2$. [219°].

Nitrosamine $C_{18}H_{14}N_4O_2$. [c. 120°].

Phenylene-di-phenyl-diamine $C_6H_4(NH_2).NPh_2$. Formed by reducing nitro-tri-phenyl-amine (Herz, *B.* 23, 2537). Crystalline.—B′HCl: silvery needles.

Acetyl derivative $C_6H_4(NHAc).NPh_2$. [197°].

o-**PHENYLENE-PHENYL-GUANIDINE** $C_6H_4<\genfrac{}{}{0pt}{}{NH}{NH}>C:NPh$. [190°]. (440°-450°).

Formed by heating phenylene *o*-diamine with di-phenyl-cyanamide at 215° (Keller, *B.* 24, 2499). White needles (from benzene) or prisms (from alcohol). Phenyl-cyanate forms the compound $NPh<\genfrac{}{}{0pt}{}{CO}{CO}>N_2(CNPh)C_6H_4$. [266°]. — B′HCl.—$B'_2H_2PtCl_6$.—$B'H_2SO_4$: long needles.

Mono-acetyl derivative. [160°].

Di-benzoyl derivative. [171°]. Needles.

PHENYLENE-DI-PHENYL-DIHYDRAZINE. *Hexahydride* $C_6H_{10}(NH.NHPh)_2$ [148°]. Formed by reducing the di-phenyl-di-hydrazide of quinone with sodium and alcohol (Baeyer a. Noyes, *B.* 22, 2175). Crystalline, sl. sol. alcohol.—$B'H_2C_2O_4$ aq.

m-**PHENYLENE DI-PHENYL DIKETONE** $C_6H_4(CO.C_6H_5)_2$. *Isophthalophenone.* [95°] (M.); [100°] (A.). (above 360°). Formed from isophthalyl chloride, benzene, and $AlCl_3$ (Ador, *Bl.* [2] 33, 56; *B.* 13, 320; Münchmeyer, *B.* 19, 1848). Plates (from alcohol). Yields a mono-oxim [201°] (Nölting a. Kohn, *B.* 19, 146), a dioxim [70°–75°], and two di-nitro- derivatives [260°] and [c. 100°].

p-**Phenylene diphenyl diketone** $C_6H_4(CO.C_6H_5)_2$. [160°]. Formed from terephthalic chloride, benzene, and $AlCl_3$ (M.). Yields a dioxim [235°].

Diphenylene di-phenyl diketone $C_{12}H_8(CO.C_6H_5)_2$. [218°]. Got from diphenyl, BzCl, and $AlCl_3$ (Wolf, *B.* 14, 2031). Crystals.

DIPHENYLENE-PHENYL-METHANE $C_{19}H_{14}$ *i.e.* $\genfrac{}{}{0pt}{}{C_6H_4}{C_6H_4}>CHPh$. [145·5°]. Formed by the action of P_2O_5 or $AlCl_3$ on a mixture of benzene and diphenylene-carbinol; and also by heating CPh_3Cl at 200° (Hemilian, *B.* 11, 202, 837; *Bl.* [2] 34, 325). Formed also in small quantity in the distillation of calcium benzoate or phthalate (Kekulé, *B.* 5, 910; Miller, *B.* 12, 1489). Needles, sl. sol. ether. Yields *o*-benzoyl-benzoic acid on oxidation.

Reference.—DI-BROMO-DI-PHENYLENE-PHENYL-METHANE.

v-*m*-**PHENYLENE-DI-PHENYL-DI-METHYL-DI-PYRROLE DI-CARBOXYLIC-ETHER** $C_{34}H_{[illegible]}O_4N_2$ *i.e.*

$$\genfrac{}{}{0pt}{}{CO_2Et.C:CMe}{HC:CPh}>N.C_6H_4.N<\genfrac{}{}{0pt}{}{CMe:C.CO_2Et}{CPh:CH}$$

[185°]. Obtained by mixing together in acetic acid solution acetophenone-aceto-acetic ether (2 mols.) and *m*-phenylene diamine (1 mol.), and allowing the mixture to stand a long time (Paal a. Schneider, *B.* 19, 3161). Slender white needles. V. sol. ordinary solvents, except Aq.

v-*p*-**Diphenylene-di-phenyl-di-methyl-di-pyrrole di-carboxylic-ether** $C_{40}H_{36}O_4N_2$ *i.e.*

$$\genfrac{}{}{0pt}{}{CO_2Et.C:CMe}{HC:CPh}>N.C_6H_4.C_6H_4.N<\genfrac{}{}{0pt}{}{CMe:C.CO_2Et}{CPh:CH}$$

[179]. Obtained by mixing together in acetic acid solution acetophenone-aceto-acetic ether (2 mols.) and benzidine (1 mol.), and allowing the mixture to stand for a long time (P. a. S.). Hair-like needles. Sol. alcohol and acetic acid, v. sol. ether, chloroform, and petroleum-spirit.

p-**PHENYLENE-TETRA-PHENYL-DI-PYRROLE DICARBOXYLIC ACID**

$$\genfrac{}{}{0pt}{}{CO_2H.C:CPh}{HC:CPh}>N.C_6H_4.N<\genfrac{}{}{0pt}{}{CPh:C.CO_2H}{CPh:CH}$$

[above 300°]. Formed by saponification of its ether [250°] which is got from phenacyl-benzoyl-acetic ether and phenylene-*p*-diamine (Paal a. Braikoff, *B.* 22, 3095). Small grains.

m-**PHENYLENE DI-PHENYL SULPHONE** $C_6H_4(SO_2Ph)_2$. [191°]. Formed by heating benzene with P_2O_5 and benzene *m*-disulphonic acid or di-phenyl sulphone *m*-sulphonic acid (Otto, *B.* 19, 2421; 20, 185). Minute needles (from HOAc). Alcoholic potash at 170° forms $O(C_6H_4.SO_2Ph)_2$ [70°] and $C_6H_5.SO_2K$.

Di-phenylene di-phenyl trisulphone $SO_2(C_6H_4.SO_2C_6H_5)_2$. [193°]. Formed from $SO_2(C_6H_4.SO_3H)_2$, benzene, and P_2O_5 at 200° (Otto a. Rössing, *B.* 19, 3127).

PHENYLENE-DI-PHENYL-DI-THIO-DI-UREA $C_6H_4(NH.CS.NHPh)_2$. Formed from phenylene-diamine and phenyl thiocarbimide in alcohol (Lellman a. Würthner, *A.* 221, 28; 228, 200). The *o*- and *p*- compounds are decomposed by heat into di-phenyl-thio-urea and phenylene-thio-urea; the *m*- compound melts at 161°, and the *o*- isomeride at about 290°. They are insol. ether.

m-**PHENYLENE-DI-PHENYL-UREA** $C_6H_4(NH.CO.NHPh)_2$. Formed from *m*-phenylene-diamine and phenyl cyanate (Kühn, *B.* 18, 1478). Amorphous.

PHENYLENE-PROPENYL-DIAMINE $C_6H_4<\genfrac{}{}{0pt}{}{NH}{N}>CEt$. [169°]. (above 360°). Got by boiling *o*-phenylene-diamine with propionic acid (Wundt, *B.* 11, 829), and by reducing propionyl-*o*-nitro-aniline with tin and HOAc (Smith, *Am.* 6, 172). Plates (from water).—B′HCl.—$B'HgCl_2$.—$B'_2H_2PtCl_6$ 2aq.—$B'_2H_2Cr_2O_7$.

PHENYLENE-DI-PROPIONIC ACIDS $C_6H_4(CH_2.CH_2.CO_2H)_2$. Formed by heating $C_6H_4(CH_2.CH(CO_2H)_2)_2$ (Perkin a. Kipping, *C. J.* 53, 8, 32; *B.* 21, 27, 40). The *o*- acid [162°] forms Ag_2A''. The *m*- acid [147°] forms Me_2A'' [51°] and Et_2A'' (250° at 60 mm.). The *p*- acid [224°] forms Ag_2A'' and Me_2A'' [115°].

p-**PHENYLENE-PROPYL-DIAMINE** $C_6H_4(NH_2)(NHPr)$. (281°). Got by reducing *p*-nitroso-propyl-aniline with $SnCl_2$ (Wacker, *A.* 243, 294). Plates.—B″2HCl. Plates, v. e. sol. Aq.

o-**PHENYLENE-PROPYLENE-DIAMINE** $C_6H_4<\genfrac{}{}{0pt}{}{NH}{NH}>C_3H_6$. [72°]. (285°). Formed by heating pyrocatechin with propylene-diamine at 200° (Ris, *B.* 21, 382). Plates (from ligroïn).—$B'_2$3HCl.—$B'_2 2C_6H_3N_3O_7$. Thin needles.

DIPHENYLENE-PYRAZINE. *Dihydride* $C_{16}H_{12}N_2$ *i.e.* $\genfrac{}{}{0pt}{}{C_6H_4.C.N.CH_2}{C_6H_4.C.N.CH_2}$. Formed from phenanthraquinone and ethylene-diamine (Mason, *B.* 19, 112; 20, 267).—$B'_2H_2PCl_6$.

(*a*)-**PHENYLENE-PYRIDYL-KETONE** $C_6H_4<\genfrac{}{}{0pt}{}{CO.C.CH:CH}{——C-N:CH}$. [141°]. Formed by distilling the dicarboxylic acid $C_7H_4O<\genfrac{}{}{0pt}{}{C.C(CO_2H):CH}{C.N\ :\ C(CO_2H)}>$ [284°], which is formed by oxidising (*a*)-styryl-(*β*)-naphthoquinoline carboxylic acid (Doebner a. Peters, *B.* 23, 1241). Yields a *picric acid compound* [197°]. The dicarboxylic acid yields Ag_2A''.

(*β*)-**Phenylene-pyridyl-ketone** $C_6H_4<\genfrac{}{}{0pt}{}{CO.C.N\ :CH}{——C.CH:CH}$. [129°]. Formed in like manner from the corresponding dicarboxylic acid [264°] which is got by oxidising (*a*)-styryl-(*a*)-naphthoquinoline carboxylic acid with $KMnO_4$. Needles. Yields $B'_2H_2PtCl_6$ 2aq. The dicarboxylic acid forms Ag_2A'' as a pp.

PHENYLENE-QUINOLYLENE KETONE OXIDE $C_{16}H_9NO_2$ *i.e.* $O<\genfrac{}{}{0pt}{}{C_6H_4}{C_9H_5N}>CO$. *Phenoquinoxanthone.* [188°]. Formed by distilling *p*-oxy-quinoline with salicylic acid. Needles (from alcohol).—B'HCl: needles.

DIPHENYLENE-QUINOXALINE $C_{20}H_{12}N_2$ *i.e.* $\genfrac{}{}{0pt}{}{C_6H_4.C.N}{C_6H_4.C.N}>C_6H_4$. [217°]. Got from phenylene-*o*-diamine and phenanthraquinone (Hinsberg, *A.* 237, 340). V. sl. sol. alcohol.

DIPHENYLENE-STYRYL-OXAZOLE $\genfrac{}{}{0pt}{}{C_6H_4.C.O}{C_6H_4.C.N}>C.CH:CHPh$. [172°]. Formed from phenanthraquinone, cinnamic aldehyde, and alcoholic NH_3 at 100° (Wadsworth, *C. J.* 57, 11). Yellow needles.

p-**PHENYLENE DISULPHIDE** $C_6H_4S_2$. Formed by oxidising dithiohydroquinone with an alkaline ferricyanide solution (Leuckart, *J. pr.* [2] 41, 206). Chars without melting at 300°, insol. ordinary solvents. Is reduced by fusing with potash to dithiohydroquinone.

Diphenylene sulphide $\genfrac{}{}{0pt}{}{C_6H_4}{C_6H_4}>S$. [97°]. (333° i.V.). Formed by passing Ph_2S through a red-hot tube (Stenhouse, *A.* 156, 332; Graebe, *A.* 174, 185). Needles, m. sol. alcohol. Yields on oxidation the sulphone $C_{12}H_8SO_2$ [230°].

Diphenylene-disulphide $C_6H_4<\genfrac{}{}{0pt}{}{S}{S}>C_6H_4$ [154°]. (366°). A product of the distillation of sodium benzene sulphonate (Stenhouse, *Pr.* 17, 62; *A.* 149, 252). Formed also by heating phenol with P_2S_5 (Graebe, *A.* 174, 185; 179, 178), by heating benzene with S and $AlCl_3$ at 80° (Friedel a. Crafts, *A. Ch.* [6] 1, 530; 14, 439), and by heating $C_6H_4<\genfrac{}{}{0pt}{}{N}{S}>N$ (Jacobson a. Elley, *B.* 22, 910). Prisms (from CS_2). Conc. H_2SO_4 forms a purple solution. CrO_3 in HOAc gives the sulphone $C_{12}H_8S_2O_4$ [325°] and the sulphoxide $C_{12}H_8S_2O_2$ [241°], sl. sol. cold benzene. Br forms $C_{12}H_8S_2Br_4$ crystallising from CS_2 in small black prisms.

m-**PHENYLENE SULPHOCYANIDE** $C_6H_4(SCN)_2$. [54°]. Formed by heating the lead salt of di-thio-resorcin with ICy and alcohol at 100° (Gabriel, *B.* 10, 184). Needles, v. e. sol. hot alcohol. Yields a nitro-compound $C_6H_3(NO_2)(SCN)_2$ [150°].

DIPHENYLENE SULPHONE *v.* DIPHENYLENE SULPHIDE.

DI-PHENYLENE SULPHONE KETONE $C_6H_4<\genfrac{}{}{0pt}{}{SO_2}{CO}>C_6H_4$. [185°]. Formed by heating benzophenone with fuming H_2SO_4 (Beckmann, *B.* 6, 1112; 8, 992), and by oxidising $C_6H_4<\genfrac{}{}{0pt}{}{S}{CO}>C_6H_4$ (Graebe a. Schultess, *A.* 263, 10). Yellowish needles, v. sol. alcohol.

PHENYLENE DITHIOCARBAMIC ETHERS $C_6H_4(NH.CO.SEt)_2$. Formed by boiling from phenylene-thiocarbimide with alcohol (Billeter a. Steiner, *B.* 20, 230). The *m*-compound [116°] and the *p*-compound [197°] are crystalline and yield Ag_2A'' as white pps.

PHENYLENE-DI-THIO-CARBIMIDE $C_6H_4(NCS)_2$. Formed from phenylene-diamine and $CSCl_2$ (Billeter a. Steiner, *B.* 20, 231). The *o*-compound [5?°], *m*-compound [53°] (250°), and *p*-compound [130°] all crystallise in needles.

m-**PHENYLENE-DI-THIO-DIGLYCOLLIC ACID** $C_6H_4(SCH_2.CO_2H)_2$. [127°]. Formed from di-thio-resorcin and $ClCH_2CO_2H$ (Gabriel *B.* 12, 1639). Microcrystalline powder.

Diphenylene-di-thio-di-glycollic acid $C_{12}H_8(S.CH_2.CO_2H)_2$. [252°]. Formed from $C_{12}H_8(SH)_2$, NaOHAq, and chloro-acetic acid (Gabriel, *B.* 13, 390).

o-**PHENYLENE-THIO-UREA** $C_6H_4<\genfrac{}{}{0pt}{}{NH}{NH}>CS$. [298°]. Formed by heating *o*-phenylene-diamine hydrochloride with ammonium sulphocyanide and water at 180 (Lellmann, *B.* 15, 2146; *A.* 221, 9). Formed also from *o*-phenylene-diamine and $CSCl_2$ (Billeter a. Steiner, *B.* 20, 231). Plates (from dilute alcohol, sl. sol. water). The crystalline *m*-isomeride is got by heating *m*-phenylene-diamine with CS_2 and some alcohol at 150° (Gucci *G.* 17, 524). The *p*-isomeride melts at 271°.

Phenylene-di-thio-di-ureas $C_6H_4(NH.CS.NH_2)_2$. *m*- [215°]. *p*- [220°] Formed by heating phenylene-diamine hydrochloride with ammonium sulphocyanide (Lellmann, *A.* 221, 11; *B.* 15, 2840). The *p*-compound is also formed from *p*-phenylene dithiocarbimide and alcoholic NH_3 (Billeter a. Steiner, *B.* 20, 230).

Diphenylene-thio-urea $\genfrac{}{}{0pt}{}{C_6H_4.NH}{C_6H_4.NH}>CS$. [238°]. Formed by heating di-*op*-amido-diphenyl with alcohol and CS_2 (Reuland, *C. J.* 58, 167; *B.* 22, 3014).

o-**PHENYLENE-TOLENYL-AMIDINE** $C_6H_4Me.C\genfrac{}{}{0pt}{}{\leqslant NH}{\leqslant N}>C_6H_4$. [268°]. Formed from *o*-phenylene-diamine and *p*-toluic chloride, and also by reduction of *p*-toluyl-*o*-nitro-aniline (Hübner, *A.* 210, 328; *cf.* Brückner, *A.* 205, 115). Prisms (from alcohol).—B'HCl.—$B'_2H_2PtCl_6$.—$B'HNO_3$.—$B'_2H_2SO_4$: slender needles.

PHENYLENE-DI-*p*-TOLYL-*m*-DIAMINE $C_{20}H_{20}N_2$ *i.e.* $C_6H_4(NH.C_6H_4Me)_2$. [187°]. Formed by heating resorcin with *p*-toluidine, $ZnCl_2$, and $CaCl_2$ (Hatschek a. Zega, *J. pr.* [2] 33, 218). Needles. Yields a di-nitrosamine $C_{20}H_{18}N_4O_2$ [c. 150°], a di-acetyl derivative

$C_{20}H_{18}Ac_2N_2$ [176°], and a di-benzoyl derivative $C_{20}H_{18}Bz_2N_2$ [152°].—B″2HCl; crystalline powder, decomposed by water.

Phenylene-di-*o*-tolyl-*p*-diamine [135°]. (420°). Formed by heating hydroquinone with *o*-toluidine and $CaCl_2$ at 290° (Philip, *J. pr.* [2] 34, 65). Plates (from HOAc). Yields a di-nitrosamine [140°]. Yields $C_{20}H_{18}Bz_2N_2$ [235°] and $C_{20}H_{18}Ac_2N_2$ [189°].—B″2HCl: needles.

Phenylene-di-*p*-tolyl-*p*-diamine. [182°]. Formed by heating hydroquinone or phenyl-*p*-amido-phenol with *p*-toluidine and $ZnCl_2$ at 220° (H. a. Z.); Calm, *B.* 16, 2810). Plates. Yields a di-nitrosamine [152°], a di-acetyl derivative [173°], and a di-benzoyl derivative [222°].—B″2HCl.

PHENYLENE-TOLYLENE-KETONE OXIDE $C_6H_4{<}\substack{CO\\O}{>}C_6H_3Me$. *Methyl-xanthone.* [105°]. Formed by boiling *p*-tolyl salicylate (Graebe a. Feer, *B.* 19, 2612; *cf.* Seifert, *J. pr.* [2] 31, 478).

Isomeride $C_6H_4{<}\substack{O\\CO}{>}C_6H_3Me\left[\substack{3\\4}\,1\right]$. [176°]. Made by heating $C_6H_3Me(OH)CO_2Ph$ [49°] (Weber, *B.* 25, 1745). Crystals (from alcohol).

***o*-PHENYLENE-*p*-TOLYL-GUANIDINE** $C_6H_4{<}\substack{NH\\NH}{>}C{:}N.C_6H_4Me$. [209°]. Formed by heating *o*-phenylene-diamine with di-*p*-tolyl-cyanamide at 210° (Keller, *B.* 24, 2509). Tables. Yields a mono-acetyl derivative [152°], a di-benzoyl derivative [191°], and a nitrosamine $C_{14}H_{12}(NO)N_3$ [150°-160°]. Phenyl cyanate forms $C_6H_5N{<}\substack{CO\\CO}{>}N_2(C_6H_4){:}C{:}NC_6H_4Me$ [254°] crystallising from benzene in small needles. Di-*p*-tolyl-cyanamide at 210° forms the compound $(NHC_7H_7)_2C{:}N_2(C_6H_4){:}C{:}N.C_6H_4Me$ [188°].

Salts.—$B'HCl$.—$B'_2H_2PtCl_6$.—$B'_2H_2SO_4$.

DIPHENYLENE-TOLYL-METHANE $C_{20}H_{16}$ *i.e.* $\substack{C_6H_4\\C_6H_4}{>}CH.C_6H_4Me$. [128°]. Formed by the action of P_2O_5 on a mixture of diphenylene-carbinol and toluene, or of $AlCl_3$ on diphenylene-carbinyl chloride dissolved in toluene (Hemilian, *B.* 11, 208; *Bl.* [2] 34, 325). Silky needles.

PHENYLENE-DI-*p*-TOLYL-DI-METHYL-*m*-DIAMINE $C_6H_4(NMe.C_6H_4Me)_2$. (c. 400°). Got by heating phenylene-di-*p*-tolyl-*m*-diamine with MeI and KOH at 150° (Hatschek a. Zega, *J. pr.* [2] 33, 223). Liquid smelling like geraniums.

The isomeric **phenylene-di-*o*-tolyl-di-methyl-*p*-diamine** (385°-390°) and **phenylene-di-*p*-tolyl-di-methyl-diamine** [153°] may be prepared in like manner (Philip, *J. pr.* [2] 34, 57; H. a. Z.).

***o*-PHENYLENE-UREA** $C_6H_4{<}\substack{NH\\NH}{>}CO$. [308°]. Formed by heating *o*-amido-phenyl-carbamic ether at 90° (Rudolph, *B.* 12, 1296), by heating *o*-amido-di-phenyl-urea (Lellmann a. Würthner, *A.* 228, 220), by heating its ethyl derivative with HCl (Sandmeyer, *B.* 19, 2654), and by the action of $COCl_2$ in toluene on a solution of *o*-phenylene-diamine hydrochloride at 100° (Hartmann, *B.* 23, 1046). Leaflets, sl. sol. water.—B′HCl. Decomposed by water.

Ethyl derivative $C_6H_4{<}\substack{NH\\N}{>}C.OEt$. [160°]. Formed from *o*-phenylene-diamine and $NH{:}C(OEt)_2$. Plates.

***m*-Phenylene-urea.** [above 300°]. Formed by similar methods (Michler a. Zimmermann, *B.* 14, 2177; L. a. W.). Insoluble powder.

***p*-Phenylene-urea.** [above 320°]. Got by heating *p*-amido-di-phenyl-urea (L. a. W.).

Isomeride. [130°]. Got by boiling an alcoholic solution of oxy-phenyl-thio-urea with HgO (Bendix, *B.* 11, 2264). Tables, sol. water.

Phenylene-di-ureas $C_6H_4(NH.CO.NH_2)_2$. *o-* [290°]. *m-* [above 300°]. Formed from phenylene-diamine hydrochloride and potassium cyanate in cold aqueous solutions (Warder, *B.* 8, 1180; Lellmann, *A.* 221, 13; *B.* 16, 592).

The *p-* compound can be heated to carbonisation without melting.

References.—AMIDO- and NITRO- PHENYLENE-UREA.

PHENYL-ENNOIC ACID.

Nitrile $C_6H_5.CH(C_7H_{15}).CN$. (327°). Formed from $CH_2Ph.CN$, heptyl iodide, and NaOH (Rossolymo, *B.* 22, 1237). Yellow oil.

DI-PHENYL-ENNYL TRICYANIDE $C_9H_{19}C_3N_3Ph_2$. [c. 38°]. (c. 293° at 15 mm.). Formed from decoic chloride, benzonitrile, and $AlCl_3$ (Krafft a. Koenig, *B.* 23, 2384).

PHENYL-ENNYL-THIO-UREA $C_{16}H_{26}N_2S$ *i.e.* $NHPh.CS.NHC_9H_{19}$. [60°]. Formed from ennyl-thiocarbimide and aniline (Freund a. Schönfeld, *B.* 24, 3359). Tables, v. sol. alcohol and ligroïn.

PHENYL-ENNYL-UREA $C_{16}H_{26}N_2O$ *i.e.* $NHPh.CO.NHC_9H_{19}$. [63°]. Formed from phenyl cyanate and aniline in alcohol (Freund a. Schönfeld, *B.* 24, 3358). Long prisms.

***s*-DI-PHENYL-ETHANE** $C_{14}H_{14}$ *i.e.* $CH_2Ph.CH_2Ph$. *Dibenzyl.* Mol. w. 182. [53°]. (277°). S.V.S. 174·2 (Schiff, *A.* 223, 261). H.F. - 31,200. H.C.v. 1,828,300. H.C.p. 1,830,200 (Berthelot a. Vieille, *Bl.* [2] 47, 866).

Formation.—1. By the action of Na on benzyl chloride (Cannizzaro a. Rossi, *A.* 121, 250; Fittig, *A.* 137, 257).—2. From ethylene chloride, benzene, and $AlCl_3$ (Silva, *C. R.* 89, 606; *A. Ph. S.* 18, 345).—3. From CHBr:CHBr, benzene, and $AlCl_3$ (Anschütz, *A.* 235, 155).—4. From acetylene, benzene, and $AlCl_3$ (Varet a. Vienne, *Bl.* [2] 47, 919).—5. By heating benzyl chloride with copper powder (Onufrovitch, *B.* 17, 833).—6. A product of the action of Na on *o*-bromo-benzyl-bromide (Jackson a. White, *Am.* 2, 390).—7. By adding sodium (70 g.) to an alcoholic solution of phenyl-cinnamonitrile (Freund a. Remse, *B.* 23, 2859).

Properties.—Long colourless needles, sol. alcohol, ether, and CS_2.

Reactions.—1. Yields toluene and di-phenyl-ethylene when passed through a *red-hot tube* (Otto, *Z.* [2] 6, 22; *A.* 154, 176; Barbier, *C. R.* 78, 1769).—2. Chlorine passed into fused *s*-di-phenyl-ethane forms first CHPh:CHPh and then $C_6H_4Cl.CH{:}CH.C_6H_4Cl$ (Kade, *J. pr.* [2] 19, 466). In presence of I, chlorine forms *p*-di-chloro-di-phenyl-ethane in the cold. Exhaustive *chlorination* yields C_2Cl_6 and C_6Cl_6 (Merz a. Weith, *B.* 16, 2877).—3. H_2SO_4 forms a disulphonic acid $C_{14}H_{12}(SO_3H)_2$ 5aq, which yields K_2A'' 2aq, BaA'' ½aq, and PbA'' aq (Kade, *B.* 6, 953). A tetra-sulphonic acid, $C_{14}H_{10}(SO_3H)_4$ 3aq, is also formed.

***u*-Di-phenyl-ethane** $CH_3.CHPh_2$. (270°) (O.); (286°) (H.).

Formation.—1. From $CCl_3.CHPh_2$, alcohol, and Na (Goldschmiedt, *B.* 6, 1501).—2. From $CH_2Ph.CH_2Br$, benzene, and zinc-dust (Radziszewski, *B.* 7, 140).—3. From paraldehyde, benzene, and H_2SO_4 (Baeyer, *B.* 7, 1190).—4. Together with ethyl-benzene and di-methyl-anthracene dihydride by heating ethylidene chloride with benzene and $AlCl_3$ (Silva, *Bl.* [2] 41, 448; Anschütz, *B.* 17, 165).—5. By distilling its dicarboxylic acid (Haiss, *B.* 15, 1481).

Properties.— Oil, with blue fluorescence. Solidifies in a freezing mixture. Yields benzophenone on oxidation. Fuming HNO_3 added to its solution in HOAc forms benzophenone, $CPh_2(OH).CH_2.O.NO_2$ [107°], di-phenyl-vinyl nitrite [87°], and a body [148°] which yields di-phenyl-acetonitrile on reduction (Anschütz a. Romig, *A.* 233, 329).

Tri-phenyl-ethane $CH_2Ph.CHPh_2$. (above 360°). Formed from $CH_2Cl.CHCl.OEt$, benzene, and $AlCl_3$ (Waas, *B.* 15, 1128). Liquid, with violet fluorescence. Insol. cold alcohol.

s-Tetra-phenyl-ethane $C_{26}H_{22}$ *i.e.* $CHPh_2.CHPh_2$. Mol. w. 334. [210°]. S. (benzene) 14 at 80°. S. (95 p.c. alcohol) ·8 on boiling.

Formation.—1. By distilling benzoyl- and succinyl- di-phenyl-carbinol and by distilling di-phenyl-carbinol with succinic acid (Linnemann, *A.* 133, 24).—2. By distilling benzophenone with zinc-dust (Staedel, *B.* 6, 1401).—3. By reducing benzpinacone $CPh_2(OH).CPh_2(OH)$ with HI and P (Graebe, *B.* 8, 1055).—4. From di-phenyl-carbinol, glacial HOAc, conc. HClAq, and zinc (Zagumenny, *A.* 184, 176; *Bl.* [2] 34, 329).—5. By reducing (β)-benzpinacolin $CPh_3.CO.C_6H_5$ with HI and P (Zincke a. Thörner, *B.* 11, 67).—6. By boiling $(CHPh_2)_2S_2$ with alcohol and copper powder (Engler, *B.* 11, 926).—7. By reducing $CPh_2:CPh_2$ (Friedel a. Balsohn, *Bl.* [2] 33, 338).—8. From $CHPh_2Cl$ and Na (Engler). 9. By the action of benzene and $AlCl_3$ on $CBr_3.CH_2Br$, on $CHBr_2.CHBr_2$, on $CPhHBr.CHBr_2$, on $CPhBr_2.CPhBr_2$, and on CHPhBr.CHPhBr, the yield in the last case being excellent (Anschütz, *A.* 235, 196).—10. By distilling CPh_2HCl (Anschütz, *A.* 235, 220).

Properties.—Needles (by sublimation), sl. sol. alcohol. Crystallises from benzene with C_6H_6. Yields a crystalline tetra-nitro- derivative, a crystalline tetra-sulphonic acid, which gives Ba_2A^{iv} and $C_{26}H_{18}(OH)_4$ [248°].

u-Tetra-phenyl-ethane $CPh_3.CH_2Ph$. [140°]. Formed from CPh_3K and benzyl chloride (Hanriot, *C. R.* 108, 1119).

References.—Amido-, Bromo-, Bromo-amido-, Di-bromo-di-nitro-, Chloro-, Penta-chloro-di-nitro-, Nitro-, and Oxy-, Phenyl-ethanes.

PHENYL-ETHANE DICARBOXYLIC ACID *v.* Carboxy-phenyl-propionic acid and Phenyl-succinic acid.

Phenyl-ethane tricarboxylic acid $CHPh(CO_2H).CH(CO_2H)_2$. [171°]. Got by saponifying its ether, which is made by the action of α-chloro- or α-bromo- phenyl-acetic ether on sodium malonic ether (Spiegel, *A.* 219, 31; Alexander, *A.* 258, 71). Small tablets, v. sol. hot water. Decomposed on fusion into CO_2 and phenyl-succinic acid. **Salts.**—$Ca_3A'''_2$ 10aq.—$Ca_3A'''_2$ 5aq: ppd. from aqueous solution by alcohol.—Ag_3A''': crystalline pp.

Ethyl ether Et_3A'''. [46°]. (202° at 10 mm.). Needles (from dilute alcohol).

Di-phenyl-ethane o-carboxylic acid $C_{15}H_{14}O_2$ *i.e.* $C_6H_5.CH_2.CH_2.C_6H_4.CO_2H$. [131°]. Formed by the action of HI and P at 200° on iso-benzylidene-phthalide, and on deoxybenzoïn carboxylic acid (Gabriel, *B.* 11, 1019; 18, 2446). Tablets (from dilute alcohol).—AgA': pp.

Isomerides *v.* Di-phenyl-propionic acid.

Di-phenyl-ethane di-o-carboxylic acid $C_{16}H_{14}O_4$ *i.e.* $CO_2H.C_6H_4.CH_2.CH_2.C_6H_4.CO_2H$. [186°] (H.); [229°] (D.).

Formation.—1. By heating diphthalyl with HI and P (Graebe, *B.* 8, 1055).—2. By the action of HI and phosphorus on the acid $CO<\begin{matrix}C_6H_4\\O\end{matrix}>CH.CH_2.C_6H_4.CO_2H$ (Wislicenus, *B.* 17, 2181; Hasselbach, *A.* 243, 254), and on diphthalylic acid (Dobreff, *A.* 239, 66).

Properties.—Small needles, v. sol. alcohol and dilute HOAc. $KMnO_4$ in alkaline solution forms diphthalylic acid [263°]. Distillation over soda-lime forms *s*-di-phenyl-ethylene.

Salts.—$(NH_4)_2A''$ (dried at 100°).—CaA' (at 100°).—BaA''.—$Cu_2A''O$.—$Pb_2A''O$.—$Zn_2A''O$.—AgHA''.

Methyl ether Me_2A''. [101°].

Ethyl ether Et_2A''. [71°]. Converted by alcoholic NH_3 into the amic ether $C_2H_4(C_6H_4.CO_2Et)(C_6H_4.CONH_2)$ [c. 67°].

Di-phenyl-ethane dicarboxylic acid $C_6H_5.CH_2.CH(CO_2H).C_6H_4.CO_2H$ [1:2]. [154°]. (above 300°). Formed by heating the nitrile with conc. HCl at 220° (Eichelbaum, *B.* 21, 2682). Small prisms, sol. alcohol, insol. ether.

Nitrile $C_6H_5.CH_2.CH(CN).C_6H_4.CN$. [110°]. (above 300°). Formed from benzyl chloride and [1:2] $C_6H_4(CN).CH_2.CN$. Plates, insol. water, alkalis, and acids.

Amide. [221°]. Formed by the action of conc. H_2SO_4 on the nitrile. Converted by conc. HCl (S.G. 1·19) at 100° into the imide  $C_6H_4<\begin{matrix}CH(C_7H_7)\\CO-NH\end{matrix}>CO$ [176°] (above 300°).

Di-phenyl-ethane di-carboxylic acid $CH_3.CH(C_6H_4.CO_2H)_2$. [275°]. Got by heating the tri-carboxylic acid (Haïss, *B.* 15, 1481). Long needles. May be sublimed.—CaA''.

Isomeride *v.* Di-phenyl-succinic acid.

Di-phenyl-ethane tri-carboxylic acid $CO_2H.CMe(C_6H_4.CO_2H)_2$. [255°]. Formed by oxidation of di-α-tolyl-propionic acid with $KMnO_4$ (Haïss, *B.* 15, 1479). Sol. alcohol and ether.—Ag_2HA'''.—Ag_3A'''.

Di-phenyl-ethane tri-carboxylic acid $C_{17}H_{14}O_6$ *i.e.* $CHPh(CO_2H).CPh(CO_2H)_2$.

Amide $CHPh(CO_2H).CPh(CO_2H).CONH_2$. [190°]. Got from $CHPh(CO_2Et).CPh(CN).CO_2Et$ [105°] which is got by heating α-chloro-phenyl-acetic ether with alcoholic KCy on a water-bath (Poppe, *B.* 23, 114).

Mono-nitrile $CO_2H.CHPh.CPh(CN).CO_2H$. The ethers Me_2A'' [101°] and Et_2A'' (*v. supra*) are got from α-chloro-phenyl-acetic acid and KCy in MeOH or EtOH. Conc. H_2SO_4 converts Et_2A'' into $CO_2Et.CHPh.CPh(CO_2Et).CONH_2$ [157°] crystallising in aggregates of needles.

References.—Nitro- and Oxy- Di-phenyl-ethane carboxylic acid.

PHENYL-ETHENYL-AMIDINE *v.* PHENYL-ACETAMIDINE.

PHENYL - ETHENYL - AMIDO - PHENYL - MERCAPTAN $C_{14}H_{11}NS$ *i.e.* $C_6H_4<^{N}_{S}>C.CH_2Ph$. Formed by heating phenyl-acetic chloride with *o*-amido-phenyl mercaptan (Hofmann, *B.* 13, 1234). Oil, sol. alcohol and ether. On fusion with potash it yields phenyl-acetic acid and amido-phenyl mercaptan.—B'HCl.—$B'_2H_2PtCl_6$ 5aq: needles.

PHENYL-ETHENYL-AMIDOXIM $C_8H_{10}N_2O$ *i.e.* $C_6H_5.CH_2.C(NOH).NH_2$. *Phenyl-acetamidoxim.* [67°]. Got by heating phenyl-acetonitrile with a solution of hydroxylamine in dilute alcohol (Knudson, *B.* 18, 1068, 2482). Thin prisms, v. sol. water. Converted by phenyl cyanate into $C_6H_5.CH_2.C(NH.CO.NHPh):NOH$ [123°].—B'HCl. [155°]. White prisms.

Acetyl derivative. [124°]. Plates.

Benzoyl derivative $C_7H_7.C(NOBz).NH_2$. [144°]. Prisms, v. sol. alcohol.

Ethyl ether $C_7H_7.C(NOEt).NH_2$. [58°]. Converted by potassium cyanate into $CH_2Ph.C(NOEt).NH.CO.NHPh$ [148°].

Benzyl ether. [55°]. Prisms.

Phenyl-ethenyl-amidoxim $CH_3.C(NOH).NHPh$. [121°]. Formed by heating thioacetic anilide with hydroxylamine solution at 100° (Müller, *B.* 22, 2408; *cf.* Nordmann, *B.* 17, 2746). Satiny plates, v. sol. alcohol. $FeCl_3$ gives a violet colour, changing to olive green and, on heating, to red.—B'HCl: needles.—$B'_2H_2PtCl_6$: yellow needles.

Benzoyl derivative $C_2H_3(NOBz).NHPh$. [110°]. White needles (from dilute alcohol).

PHENYL-ETHENYL-AZOXIM *v.* AZOXIMS.

PHENYL-ETHENYL - DI-ETHYL - TRI - SULPHONE $CH_3.C(SO_2Et)_2(SO_2Ph)$. [109°]. Got by oxidation of $CH_3.C(SPh)(SO_2Et)_2$ (Laves, *B.* 25, 364). Needles, v. sol. alcohol.

TRI-PHENYL ETHENYL TRISULPHONE $CH_3.C(SO_2Ph)_3$. [182°]. Formed by the action of alcoholic NaOH, and MeI on $CH(SO_2Ph)_3$. Got also by oxidation of $CH_3.C(SPh)_3$ by $KMnO_4$ (Laves, *B.* 25, 352). Needles, v. sol. $CHCl_3$.

DI-PHENYL-ETHENYL-DI-UREA NHPh.CO.N:CMe.NH.CO.NHPh. [169°]. Formed by adding aqueous NaOH (2 mols.) to an aqueous solution of acetamidine hydrochloride (2 mols.) shaken with phenyl cyanate (1 mol.) (Pinner, *B.* 23, 2923). Needles, m. sol. alcohol. Converted by boiling dilute (50 p.c.) acetic acid into acetyl-phenyl-urea [183°].

PHENYL ETHER *v.* DI-PHENYL OXIDE.

α-PHENYL-ETHYL ALCOHOL $C_8H_{10}O$ *i.e.* $CH_3.CHPh.OH$. Mol. w. 122. (203°). S.G. 1·013. Formed from $CH_3.CHBr.C_6H_5$ by successive treatment with AgOAc and NaOH (Radziszewski, *B.* 7, 141; Berthelot, *Z.* 1868, 589). Got also by reducing acetophenone with sodium-amalgam (Emmerling a. Engler, *B.* 6, 1005). Yields an acetyl derivative C_8H_9OAc (217°–220°) which yields styrene on treatment with alcoholic potash.

Ethyl ether C_8H_9OEt. (186°). S.G. ^{22} ·931. Formed from $CH_3.CHBr.C_6H_5$ and alcoholic NH_3 at 100° (Thorpe, *Z.* 1871, 131).

β-Phenyl - ethyl alcohol $CH_2Ph.CH_2OH$. *Benzyl-carbinol.* (212°). S.G. ^{21} 1·034. Formed by reducing phenyl-acetic aldehyde with sodium-amalgam (Radziszewski, *B.* 9, 373). Oil. Ac_2O at 150° converts it into an acetyl derivative C_8H_9OAc, (224°), S.G. 1·029.

PHENYL-ETHYL-ALLOPHANIC ETHER $C_{12}H_{16}N_2O_3$ *i.e.* $C_8H_9.NH.CO.NH.CO_2Et$. [106°]. Formed from phenyl-ethyl-urea and $ClCO_2Et$ (Neubert, *B.* 19, 1825). Needles (from water).

PHENYL-ETHYL-ALLYL-GUANIDINE $C_{12}H_{17}N_3$ *i.e.* $CN_3H_2PhEt(C_3H_5)$. Formed by boiling ethyl-allyl-thio-urea with NHPh.HgCl and alcohol (Forster, *A.* 175, 41).—$B'HgCl_2$ aq.

PHENYL-ETHYL-ALLYL-THIO-UREA $NH(C_3H_5).CS.NPhEt$. [c. 26°]. Formed from allyl-thiocarbimide and ethyl-aniline (Gebhardt, *B.* 17, 3037). Colourless very soluble crystals.

PHENYL - ETHYL - ω - AMIDO - ACETOPHENONE $C_{16}H_{17}NO$ *i.e.* $C_6H_5.CO.CH_2.NPhEt$. [95°]. Formed from ω-bromo-acetophenone and diethyl-aniline (Weller, *B.* 16, 26). Needles.

PHENYL ETHYLAMIDO - ETHYL SULPHONE $C_6H_5.SO_2.C_2H_4.NHEt$. Formed from $C_2H_4(SO_2C_6H_5)_2$ and ethylamine at 85° (Otto, *J. pr.* [2] 30, 337).—B'HCl. [130°]. Needles.

PHENYL - ETHYL - AMIDO - (α) - NAPHTHOQUINONE $C_{10}H_5(NPhEt)O_2$. [155°]. Formed by heating (α)-naphthoquinone (2 pts.) with ethyl-aniline (3 pts.) and HOAc (5 pts.) (Elsbach, *B.* 15, 1810). Violet needles (from alcohol).—B'HCl. [c. 230°]. Yellow needles, decomposed by water.

Phenyl - ethyl - amido - (β) - naphthoquinone. [165°]. Formed by heating (β)-naphthoquinone with ethyl-aniline and alcohol (Elsbach, *B.* 15, 691). Dark-red needles (from ether). Decomposed by boiling HClAq into ethyl-aniline and oxy-naphthoquinone.

PHENYL-ETHYL-AMIDO-PHENOL. *Ethyl ether* $C_{16}H_{19}NO$ *i.e.* $NPhEt.C_6H_4.OEt$. (319°). Formed by heating phenyl-*p*-amido-phenol with alcoholic potash and EtI (Philip a. Calm, *B.* 17, 2434). Oil.

α-PHENYL-ETHYL-AMINE $C_8H_{11}N$ *i.e.* $CH_3.CHPh.NH_2$. (187·5° i.V.). S. 4·166 at 20°. Formed by reducing the phenyl-hydrazide or the oxim of acetophenone in alcoholic solution with HOAc and sodium-amalgam (Tafel, *B.* 19, 1929; 22, 1856; Kraft, *B.* 23, 2783). Formed also from acetophenone and sodium formate (Leuckart a. Janssen, *B.* 22, 1413). Liquid, miscible with alcohol and ether.—B'HCl. [158°].—$B'_2H_2PtCl_6$.—$B'_2H_2SO_4$. [170°].—$B'_2H_2C_2O_4$. [238°]. Prisms, almost insol. alcohol.—$B'H_2C_2O_4$. Plates, m. sol. boiling alcohol.

Isomerides:— AMIDO-PHENYL-ETHANE and ETHYL-ANILINE.

Di-phenyl-ethyl-amine $C_{14}H_{15}N$ *i.e.* NPh_2Et. *Ethyl diphenylamine.* (296°) (Girard, *Bl.* [2] 23, 3); (286°) (Lippmann a. Fleissner, *M.* 4, 797). Got by heating diphenylamine with alcohol and HClAq. Oil.

Di-phenyl-ethyl-amine $CHPh_2.CH_2NH_2$. Formed by reducing di-phenyl-acetonitrile in alcohol with Na (Freund a. Immerwahr, *B.* 23, 2845). Oil.—B'HCl. [255°]. V. sol. water.

Di-phenyl-ethyl-amine $CH_2Ph.CHPh.NH_2$. (310°) at 737 mm. Formed by heating deoxybenzoïn (1 pt.) with ammonium formate (2 pts.) at 225° (Leuckhart a. Janssen, *B.* 22, 1409). Liquid, sl. sol. water. Potassium cyanate forms $C_2H_3Ph_2.NH.CO.NH_2$ [99°]. Phenylthiocarbimide forms the corresponding $C_2H_3Ph_2NH.CS$ NHPh

[170°]; while phenyl cyanate gives the compound $C_2H_3Ph_2.NH.CO.NHPh$ [129].—B'HCl.—$B'_2H_2PtCl_6$.—$B'HNO_3$: needles.—$B'H_2SO_4$.

Acetyl derivative. [148°]. Needles.

Benzoyl derivative. [178°]. Needles.

Di-phenyl-di-ethyl-amine $NH(CH_2.CH_2Ph)_2$. (336° at 603 mm.). Formed, together with $NH_2.CH_2.CH_2Ph$ and $N(CH_2.CH_2Ph)_3$ by the action of zinc and HClAq on phenyl-acetonitrile (Spica, *G.* 9, 567). Formed also by distilling $CH_2Ph.CH_2.NH_3Cl$ (Fileti a. Piccini, *G.* 9, 294). Liquid, sl. sol. water.—B'HCl. [270°]. Pearly scales.—$B'_2H_2PtCl_6$, m. sol. water.

Tri-phenyl-ethyl-amine $CPh_3.CH_2.NH_2$. [116°]. Formed by reducing $CPh_3.CN$ with zinc and HClAq (Elbs, *B.* 17, 700).—B'HCl. [247°].

Tri-phenyl-tri-ethyl-amine $N(CH_2.CH_2Ph)_3$. A product of the action of zinc and HCl on phenyl-acetonitrile (Spica, *G.* 9, 567). Oil.—B'HCl. [138°]. Needles, sl. sol. water.

PHENYL-ETHYL-ARSINE *v.* vol. i. p. 321.

PHENYL-ETHYL-TRIAZOLE CARBOXYLIC ACID $\begin{matrix}N.NPh\\CEt:N\end{matrix}\!\!>C.CO_2H$. [145°]. Got by saponifying its nitrile (Bladin, *B.* 18, 1548; 25, 175). Melts at 123° when crystallised from water or alcohol, but at 145° when crystallised from benzene.—B'HCl: plates.—CuA'_2 3½aq.—AgA': crystalline pp.

Methyl ether MeA'. [41°].

Ethyl ether EtA'. Oil.

Nitrile $C_{11}H_{10}N_4$. [38°]. Formed by the action of propionic anhydride on phenyl-hydrazine dicyanide. Converted by alcoholic NH_3 and H_2S into $C_2N_3PhEt.CS.NH_2$ [150°] which crystallises in yellow prisms.

Amide $C_2N_3PhEt.CO.NH_2$. [152·5°]. Formed from the nitrile, alcoholic potash, and H_2O_2. Small prisms, sl. sol. water.

DI-PHENYL-DI-ETHYL-DITRIAZYL $C_{20}H_{20}N_6$ *i.e.*  $\begin{matrix}CEt.N\\N.NPh\end{matrix}\!\!>C.C<\!\!\begin{matrix}N\cdot CEt\\NPh.N\end{matrix}$. [187°]. Formed by boiling phenyl-hydrazine dicyanide with propionic anhydride (Bladin, *B.* 22, 3115). Groups of prisms.—B''2HCl: minute prisms, decomposed by water.

PHENYL-ETHYL-CARBAMIC CHLORIDE NPhEt.COCl. [c. 52°]. Formed from ethyl-aniline and CO_2 (Michler, *B.* 9, 396). Needles.

PHENYL-ETHYL-SEMICARBAZIDE $C_9H_{13}N_3O$ *i.e.* NHPh.CO.NH.NHEt. [112°]. Formed from ethyl-hydrazine and phenyl cyanate (E. Fischer, *A.* 199, 295). Thin plates, m. sol. hot water. Yields a crystalline nitrosamine.

Phenyl-ethyl-semicarbazide NHEt.CO.NH.NHPh. [151°]. Formed from phenyl-hydrazine and ethyl cyanate (Fischer, *A.* 190, 109). Monoclinic tables (from dilute alcohol) $a:b:c = \cdot827:1:1\cdot146$; $\beta = 61°$. Gives a bluish-black pp. with cold Fehling's solution, and Cu_2O on warming. Its nitrosamine crystallises from acetone in yellow needles [86·5°].

PHENYL ETHYL CARBONATE $C_9H_{10}O_3$ *i.e.* $C_6H_5O.CO.OEt$. (*c.* 234°) (P.). S.G. $\frac{0}{4}$ 1·1134 (P.). Formed from KOPh and $ClCO_2Et$ (Fatianoff, *Z.* 1864, 77). Formed also by the action of $AlCl_3$ on a mixture of phenol and $ClCO_2Et$ (Pawlewski, *B.* 17, 1205). Liquid. By long heating at 300° it is split up into Ph_2CO_3 and Et_2CO_3 (Bender, *B.* 19, 2268).

Reference.—NITRO-PHENYL ETHYL CARBONATE.

PHENYL-ETHYL-CYANAMIDE. Formed by boiling phenyl-ethyl-thio-urea in benzene with PbO (Weith, *B.* 8, 1530). Vitreous mass.

DI-PHENYL-ETHYL-TRICYANIDE $C_3N_3Ph_2Et$. V.D. 129. [67°]. (234° at 15 mm.). Formed by the action of $AlCl_3$ on a mixture of benzonitrile and propionyl chloride at 70° (Krafft a. von Hausen, *B.* 22, 806).—$B''H_2PtCl_6$.

PHENYL-ETHYLENE *v.* STYRENE.

s-Di-phenyl-ethylene $C_{14}H_{12}$, *i.e.* CHPh:CHPh. *Stilbene.* Mol. w. 180. [124°]. (307° i.V.). H.C.v. 1,775,600. H.C.p. 1,777,300 (from diamond) (Berthelot a. Vieille, *A. Ch.* [10] 4, 50); 1,773,331 (Ossipoff, *Z. P. C.* 2, 646).

Formation.—1. By the dry distillation of benzyl, or benzylidene, sulphide (Laurent, *B. J.* 25, 616; Maercker, *A.* 136, 91; Anschütz, *A.* 235, 206).—2. By distilling benzoic aldehyde with Na (Williams, *Z.* 1867, 432).—3. By heating benzoic aldehyde with phenyl-acetic acid and NaOAc at 250°; the yield being 55 p.c. (Michael, *Am.* 1, 313).—4. From *s*-di-phenyl-ethane and Cl (Kade, *J. pr.* [2] 19, 465).—5. By heating benzylidene chloride with Na or with alcohol and zinc-dust (Limpricht, *A.* 139, 318; Lippmann, *J.* 1877, 405).—6. By passing *s*-di-phenyl-ethane through a red-hot tube (Otto a. Dreher, *A.* 154, 177).—7. By heating benzoïn with zinc-dust (Limpricht, *A.* 155, 80).—8. By passing toluene over heated PbO (Behr a. Dorp, *B.* 6, 754).—9. By heating di-phenyl-acetylene with HI and P at 175° (Barbier, *J.* 1874, 421).—10. By distilling lead phenyl-acetate with sulphur (Radziszewski, *B.* 6, 390).—11. Together with benzonitrile by the action of zinc-dust and HCl on $C_6H_5.CSNH_2$ (Bamberger, *B.* 21, 55).—12. By heating di-phenyl-fumarate or di-phenyl-cinnamate (Anschütz, *B.* 18, 1945).—13. By heating CHPhBr.CHPhBr with alcoholic KSH in a sealed tube at 100° (Auwers, *B.* 24, 1779). 14. By heating thio-benzoic aldehyde at 190° (Baumann a. Klett, *B.* 24, 3308).

Properties.—Monoclinic plates, v. sol. ether, sl. sol. cold alcohol. Combines with N_2O_4 forming $C_2H_2Ph_2N_2O_4$ [c. 300°] crystallising in needles, sl. sol. hot alcohol (Gabriel, *B.* 18, 2438). Picryl chloride forms a combination $C_{14}H_{12}C_6H_2(NO_2)_3Cl$ [71°] (Liebermann, *B.* 8, 378).

Reactions.—1. Yields phenanthrene and toluene when passed through a *red-hot tube* (Graebe, *B.* 6, 126).—2. Reduced by HIAq at 150° to *s*-di-phenyl-ethane (Limpricht a. Schwanert, *A.* 145, 333).—3. *Bromine* added to an ethereal solution forms a product containing $C_{14}H_8Br_2O_2$ [121°] which gives rise to $C_{14}H_8Br_4O_2$ [150°] and $C_{14}H_5Br_5O_2$ [206°] and when dissolved in alcohol and reduced by sodium-amalgam yields $C_{14}H_{10}O_2$, crystallising from alcohol in flat plates [172°], whence PCl_5 forms $C_{14}H_9ClO_2$ [58°], $C_{14}H_7Cl_3O_2$ [87°], and $C_{14}H_5Cl_5O_2$ [190°] (Limpricht a. Schwanert, *A.* 153, 121).—4. Fuming HNO_3 added to an ethereal solution forms $C_{14}H_{11}N_3O_2$ [220°], which is converted by boiling alcohol into $C_{28}H_{22}N_2O_4$ [57°-73°] (Lorenz, *B.* 7, 1097; 8, 1050).

u-Di-phenyl-ethylene $CH_2:CPh_2$. (277°); (162° at 15 mm.). Formed by boiling $CHPh_2.CH_2Cl$ with alcoholic potash (Hepp, *B.* 7, 1409). Formed also by the action of benzene and $AlCl_3$ on

CH_2:CBr_2 and on CHBr:CBr_2 (Demole, *B.* 12, 2245; Anschütz, *A.* 235, 154. Liquid. Oxidised by CrO_3 to benzophenone. Combines with Br, forming $CPh_2Br.CH_2Br$, which readily gives off HBr, and forms bromo-di-phenyl-ethylene [40°] (c. 170° at 11 mm.).

Isomeride. [190°]. A product of the action of alcoholic potash on *exo*-chloro-di-phenyl-ethane (Hepp, *B.* 7, 1412). Small plates (from ether), v. sl. sol. alcohol.

Tetra-phenyl-ethylene $C_{26}H_{20}$ *i.e.* C_2Ph_4. Mol. w. 332. [221°]. (193° at 30 mm.).

Formation.—1. By heating CPh_2Cl_2 with finely-divided silver (Behr, *B.* 3, 751; 5, 277).—2. By heating benzophenone with zinc-dust (Staedel, *B.* 6, 178; *A.* 194, 307).—3. By strongly heating chloro-di-phenyl-ethane (Engler a. Bethge, *A.* 174, 194).—4. From CPh_2Br, by repeated distillation (Friedel a. Balsohn, *Bl.* [2] 33, 337).—5. A by-product in the preparation of tri-phenyl-methane from benzene, chloroform, and $AlCl_3$ (Schwarz, *B.* 14, 1526).

Preparation.—1. By adding Br to di-phenyl-methane and warming the resulting $CHPh_2Br$; the yield is 80 p.c. (Boissieu, *Bl.* [2] 49, 681).—2. By heating di-phenyl-methane (20 g.) with sulphur (8 g.) for 9 hours to 250°, and finally for one hour to 290°, exhausting with ether, and recrystallising the residue from benzene; the yield is 75 p.c. (Ziegler, *B.* 21, 780).

Properties.—White needles, v. sol. hot benzene and CS_2, v. sl. sol. ether. Yields benzophenone (2 mols.) on oxidation (Anschütz, *A.* 235, 221). Yields a tetrasulphonic acid.

Isomeride $C_{13}H_{10}$? [244°]. Formed by heating (α)-benzpinacolin with soda-lime at 370° (Zincke a. Thörner, *B.* 11, 1397). Needles (from alcohol). Perhaps identical with the preceding.

References.—Di-amido-, Bromo-, Di-chloro-, Di-iodo-, Nitro-, Nitro-amido-, and Oxy- Phenyl-ethylene.

PHENYL-ETHYLENE-DIAMINE $C_8H_{12}N_2$ *i.e.* $C_6H_5NH.CH_2.CH_2.NH_2$. (262° uncor.). Formed by boiling phenyl-amido-ethyl-phthalimide (got from bromo-ethyl-phthalimide and aniline) with conc. HClAq (Gabriel, *B.* 22, 2224). Liquid, miscible with water, forming an alkaline solution. Absorbs CO_2 from the air, forming a crystalline carbonate.—B''2HCl: small greenish needles, acid in reaction.—B''HCl. Neutral to methyl-orange.—B''H_2Br_2.—**Picrate** [143°]. Flat yellow tables.

Di-acetyl derivative $C_8H_{10}Ac_2N_2$. [116°]. Crystals, v. e. sol. Aq (Newman, *B.* 24, 2193).

Di-benzoyl derivative. [143·5°]. Prisms.

Phenyl-di-ethylene-triamine $C_6H_5N(C_2H_4.NH_2)_2$. (above 300°). Formed by the action of boiling conc. HBr upon its di-phthalyl derivative $NPh(C_2H_4.N:C_8H_4O_2)_2$ [211°], which is a product of the action of aniline on bromo-ethyl-phthalimide at 100°–180° (G.). Thick ammoniacal liquid, miscible with water. Absorbs CO_2 from the air.—B''H_3Br_3.—**Picrate.** [202°]. Needles (from alcohol).

Di-phenyl-ethylene-diamine $C_{14}H_{16}N_2$ *i.e.* $C_2H_4(NHPh)_2$. [63°]. Prepared by heating ethylene bromide (1 mol.) with aniline (4 mols.); the yield being 80 p.c. of the theoretical (Morley, *B.* 12, 1794; *cf.* Hofmann, *Pr.* 10, 104; Gretillat, *M. S.* [3] 3, 383). Plates, v. sol. alcohol. Yields a di-nitrosamine $C_2H_4(NPh.NO)_2$ [157°]. Reacts with benzoic aldehyde forming the compound $C_2H_4(NPh)_2$:CHPh [137°], while cuminic, salicylic, anisic, isobutyric, and heptoic aldehydes yield corresponding compounds [125°], [116°], [164°], and [95°] respectively (Moos, *B.* 20, 732).—B''2HCl.—B''H_2PtCl_6.

Mono-acetyl derivative. [128°]. Got by heating the base with chloro-acetic acid and NaOAc at 170° (Bischoff a. Nastvogel, *B.* 22, 1783).

Di-acetyl derivative. [158°]. Crystals.

Di-phenyl-ethylene-diamine $C_{14}H_{16}N_2$ *i.e.* $CHPh(NH_2).CHPh(NH_2)$. [121°]. Formed, together with benzoic aldehyde, by the action of boiling HClAq on $C_{28}H_{24}N_2$, which is a product of the action of Na on amarine (Grossmann, *B.* 22, 2299). Formed also by the action of ammonia on the hydrocyanide of benzoic aldehyde (Limpricht a. Müller, *A.* 111, 142). Is perhaps identical with lophine. Plates (from hot water). Reacts with benzoic aldehyde forming CHPh:N.CHPh.CHPh.N:CHPh [164°], *m*-nitro-benzoic aldehyde forming $C_{28}H_{22}N_4O_2$ [161°], with salicylic aldehyde forming $C_{28}H_{24}N_2O_2$ [205°], and with cuminol forming a compound [168°].—B''2HCl. White needles (from hot water).—B''H_2PtCl_6: dark-yellow crystals.

Di-acetyl derivative. [above 350°].

Phthalyl derivative C_6H_4:C_2O_2:N_2H_2:$C_2H_2Ph_2$. [213°]. Minute crystals.

Di-phenyl-di-ethylene-diamine $C_{16}H_{18}N_2$ *i.e.*

$NPh\left<\begin{matrix}C_2H_4\\C_2H_4\end{matrix}\right>NPh$. *Diphenylpiperazine. Di-phenylpyrazine hexahydride.* [163°]. (c. 300°). Prepared by heating ethylene bromide (1 pt.) with aniline (1 pt.) and NaOAc, and by the action of ethylene bromide on di-phenyl-ethylene-diamine at 120° (Morley, *B.* 12, 1795; Bischoff, *B.* 22, 1777; *cf.* Hofmann, *Pr.* 9, 277; 10, 104; Lellmann a. Schleich, *B.* 22, 1387; Bischoff, *B.* 22, 1778). Formed also by heating pyrazine hexahydride (1 pt.) with bromo-benzene (11 pts.) at 270° (Schmidt a. Wichmann, *B.* 24, 3239). Needles, sol. alcohol and ether. Its solutions are neutral to litmus. Yields a crystalline di-nitroso-derivative which may be reduced by tin and HCl to

$C_6H_3(NH_2)N\left<\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}\right>NC_6H_3NH_2$, which, when diazotised and combined with naphthyl-amine sulphonic acid, yields a colouring matter which dyes cotton.—B''2HCl.—B''H_2PtCl_6.

Methyl-iodide B'MeI. Crystalline. Yields $B'_2Me_2PtCl_6$.

Ethylo-iodide B'EtI. [100°]. Yields $B'_2Et_2PtCl_6$.

References.—Nitro- and Oxy- Di-phenyl-ethylene-diamine.

DI-PHENYL-ETHYLENE-DI-BENZYL-DI-AMINE $CHPh(NHCH_2Ph).CHPh(NHCH_2Ph)$. [153°]. Formed by reducing the compound CHPh(N:CHPh).CHPh(N:CHPh) [163°], which is itself got by reducing amarine with Na (Grossmann, *B.* 22, 2301). White needles.

DI-PHENYL-ETHYLENE-DICARBAMIC ACID $C_2H_4(NPh.CO_2H)_2$.

Ethyl ether Et_2A''. [88°]. Needles.

Chloride $C_2H_4(NPh.COCl)_2$. [183°]. Formed from di-phenyl-ethylene-diamine and $COCl_2$ (Hanssen, *B.* 20, 781). Prisms.

DI-PHENYL-ETHYLENE DI-*o*-CARBOXYLIC ACID $C_6H_4(CO_2H).CH:CH.C_6H_4.CO_2H$. [26[illegible]°]. Formed by heating for four hours at 215° $CO<\substack{C_6H_4\\O}>CH.CH_2.C_6H_4.CO_2H$ (2 pts.) with KCy (5 pts.) (Hasselbach, *A.* 243, 258). Small needles (from dilute HOAc). Changes on heating into the parent acid [196°]. Reduced by conc. HIAq to $C_2H_4(C_6H_4.CO_2H)_2$ [185°].—Ag_2A''. Flocculent pp.

Ethyl ether Et₂A''. [80°]. Needles.

Isomeride *v.* DI-PHENYL-MALEÏC ACID.

References.—NITRO- and OXY- DI-PHENYL-ETHYLENE CARBOXYLIC ACIDS.

DI-PHENYL-ETHYLENE-DI-ETHYL-DIAMINE $C_{18}H_{24}N_2$ *i.e.* $C_2H_4(NPhEt)_2$. [70°]. Formed from di-phenyl-ethylene-diamine and EtI (Hofmann, *Pr.* 10, 104).—$B''2HI$.—$B''H_2PtCl_6$: needles.

PHENYL-ETHYLENE-GLYCOL *v.* DI-OXY-ETHYL-BENZENE.

DI-PHENYL-ETHYLENE-DI-HYDRAZINE $C_{14}H_{18}N_4$ *i.e.* $C_2H_4(NPh.NH_2)_2$. [90°]. Formed from sodium phenyl-hydrazine and ethylene bromide in benzene (Burchard a. Michaelis, *B.* 21, 3202; *A.* 254, 116). Prisms or plates. Aldehyde forms $C_2H_4(NPh.N:CHMe)_2$ [82°]. Benzoic aldehyde forms an analogous body [193°]. Acetone and acetophenone form analogous compounds [72°] and [118°]. Phenyl-thiocarbimide forms $NH_2.NPh.C_2H_4.NPh.NH.CS.NHPh$ [164°] and $C_2H_4(NPh.NH.CS.NHPh)_2$ [194°]. Yields a crystalline nitroso- derivative [160°]. $SOCl_2$ forms $C_2H_4(NPh.N:SO)_2$ [123°] (Michaelis a. Ruhl, *A.* 170, 122).—$B''H_2Cl_2$. [212°]. Needles, sl. sol. HClAq.—$B''H_2SO_4$.—$B''2HNO_3$ [173°].—$B''H_2C_2O_4$ [183°].

Acetyl derivative $C_{14}H_{16}Ac_2N_2$. [222°].

Succinyl derivative $C_{14}H_{16}N_2:C_4H_4O_2$. [c. 126°].

Succinoxyl derivative $C_2H_4(NPh.NH.CO.C_2H_4.CO_2H)_2$. [203°].

Oxalyl derivative $C_{14}H_{16}N_2:C_2O_2$. [c. 183°].

Di-phenyl-di-ethylene-dihydrazine $(C_2H_4)_2(N_2HPh)_2$. [178°]. Got by heating phenyl-hydrazine with $C_2H_4Br_2$ and alcohol (Marckwald, *C. C.* 1888, 1410).

DI-PHENYL ETHYLENE DIKETONE $C_6H_5.CO.CH_2.CH_2.CO.C_6H_5$. *Diphenacyl. Succinophenone.* [134°] (A.); [140°] (C.); [142°-145°] (P.). *Formation.*—1. Together with the isomeric $\substack{CH_2.CO\\CH_2.CPh_2}>O$, by the action of succinyl chloride and $AlCl_3$ on benzene (Auger, *A. Ch.* [6] 22, 312; Claus, *B.* 20, 1374).—2. From acetophenone by treatment with fuming HNO_3 and reduction of the resulting $C_{16}H_{10}N_2O_4$ by zinc-dust and HOAc (Hollemann, *B.* 20, 3361).—3. By the action of KOHAq on di-benzoyl-propionic acid suspended in alcohol (Paal, *B.* 21, 3056).

Properties.—Needles, v. sol. ether.

Oxim $C_2H_4(CPh:NOH)_2$. [204°].

Phenyl-hydrazide $C_2H_4(CPh:N_2HPh)_2$. [180°]. Needles, v. sol. ether.

DI-PHENYL ETHYLENE DIKETONE CARBOXYLIC ACID *v.* PHENACYL-BENZOYL-ACETIC ETHER.

Di-phenyl-ethylene diketone di-*o*-carboxylic acid $C_{18}H_{14}O_6$ *i.e.* $C_2H_4(CO.C_6H_4.CO_2H)_2$ [172°]. Obtained by boiling di-phthalyl-ethane with alkalis (Gabriel a. Michael, *B.* 10, 1561, 2199; Roser, *B.* 17, 2622; 18, 803, 3115; Baumann, *B.* 20, 1486). Prisms (from water), v. sol. alcohol. Reconverted by conc. H_2SO_4 into di-phthalyl ethane $C_2H_4(C_2O_2C_6H_4)_2$. A boiling alcoholic solution of phenyl-hydrazine forms $C_{30}H_{22}N_4O_2$ [237°]. Hydroxylamine at 100° gives rise to $C_2H_4\left(C\lessdot\substack{C_6H_4\\N.O}>CO\right)_2$ [270°] (Baumann, *B.* 20, 1492).—Ag_2A'': small plates, sl. sol. hot water.

(*a*)-*Anhydride* $C_{18}H_{12}O_5$. [230°]. Got by heating the acid alone, or together with diphthalyl-ethane, by heating it for a short time with HCl. Needles (from alcohol).

(*β*)-*Anhydride* $C_{18}H_{12}O_5$. [202°]. Formed by more prolonged heating of the acid with HCl, and also, together with the (*a*)-isomeride, by heating the acid by itself. Prisms (from alcohol). Both anhydrides are reconverted into the acid by boiling alkalis, and into di-phthalyl-ethane by elimination of H_2O.

Isomeride *v.* DI-BENZOYL-SUCCINIC ACID.

PHENYL-ETHYLENE OXIDE $\substack{CH_2\\CHPh}>O$. (260° at 50 mm.). Formed by heating di-oxy-ethyl-benzene with dilute H_2SO_4 (Breuer a. Zincke, *B.* 11, 1402). Oil. Converted by PBr_5 into $CHPhBr.CH_2Br$.

Tetra-phenyl-ethylene oxide *v.* BENZPINACOLIN.

PHENYL-ETHYLENE SULPHIDE $\substack{CH_2\\CHPh}>S$. S.G. $\frac{16}{}$ 1·099. Formed from $PhCHBr.CH_2Br$ by successive treatment with alcoholic KSHAq (Spring a. Marsenille, *Bl.* [3] 7, 13). Oil with strong smell, sol. alcohol-ether. Oxidised by CrO_3 to benzoic acid.

Di-phenyl-ethylene sulphide $\substack{CHPh\\CHPh}>S$. [169°]. A product of the distillation of benzyl sulphide (Barbier, *J.* 1876, 421). Needles.

Di-phenyl-ethylene disulphide $C_2H_4(SPh)_2$. [65°]. Formed from NaSPh and $C_2H_4Br_2$ (Ewerlöf, *B.* 4, 716). Needles, insol. water.

DI-PHENYL-ETHYLENE DISULPHONE $C_2H_4(SO_2C_6H_5)_2$. [180°].

Formation.—1. By oxidation of $C_2H_4(SPh)_2$ (Ewerlöf, *B.* 4, 717).—2. By boiling sodium benzene sulphinate (100 pts.) with $C_2H_4Br_2$ (58 pts.) in alcohol (Otto, *B.* 13, 1279; *J. pr.* [2] 30, 174). 3. By adding $CH_3.CCl_2.CO_2Na$ (1 mol.) to $C_6H_5.SO_2Na$ (2 mols.) in weak alcoholic solution, kept neutral by Na_2CO_3 (Otto, *J. pr.* [2] 40, 531). 4. By heating $CH_3.CCl_3$ with $C_6H_5.SO_2Na$ at 160° (Otto, *B.* 21, 1691).

Properties.—Triclinic needles or plates, sl. sol. water, m. sol. alcohol, v. sol. HOAc.

Reactions.—1. *Sodium-amalgam* reduces it to alcohol and $C_6H_5SO_2Na$, which is finally reduced to C_6H_5SNa.—2. *Chlorine* in diffused daylight forms $C_2H_4Cl_2$ and benzene sulphonic chloride. In sunlight the products are $C_2H_4Cl_2$, SO_2Cl_2, and chlorinated benzenes.—3. Boiling aqueous KOH splits it up into $C_6H_5SO_2K$ and $C_6H_5.SO_2.C_2H_4.OH$. Conc. KOHAq forms a compound [88°] crystallising from alcohol.—4. Aqueous NH_3 forms $C_6H_5.SO.ONH_4$ and $(C_6H_5.SO_2.CH_2.CH_2)_2NH$ [78°] which yields $B'HCl$ [193°], $B'_2H_2PtCl_6$, a nitrate [190°], and the derivatives $(C_6H_5.SO_2.CH_2.CH_2)_2NMe$ and $(C_6H_5.SO_2.CH_2.CH_2)_2NMeHCl$ [221°].—5. Aqueous *ethylamine* forms $C_6H_5.SO_2NH.Et$ and $C_6H_5.SO_2.C_2H_4NHEt$, an oil which yields B'HCl [130°].—6. Alcoholic KCy forms $C_6H_5SO_2K$ and $C_2H_4(CN)_2$.

PHENYL-ETHYLENE-THIO-UREA $CS{<}\begin{matrix}NPh\\NH\end{matrix}{>}C_2H_4$. [155°]. Formed from phenyl-ethylene-diamine and CS_2 (Newman, *B.* 24, 2191). White plates, v. sol. alcohol.

Di-phenyl-ethylene-ψ-thio-urea $C_2H_4{<}\begin{matrix}NPh\\S\end{matrix}{>}C{:}NPh$. [136°]. (above 300°). Formed by heating di-phenyl-thio-urea with ethylene bromide (Will, *B.* 14, 1490; 15, 343). Plates (from alcohol). $KClO_3$ and HClAq form $C_{15}H_{14}N_2SO_3$ [187°] (Andreasch, *M.* 4, 134).—$B'H_2SO_4$: thick prisms, v. sol. water.

Di-phenyl-ethylene-di-thio-di-urea $C_{16}H_{18}N_4S_2$ *i.e.* $C_2H_4(NH.CS.NHPh)_2$. [193°]. Formed from $C_2H_4(NH_2)_2$ and phenyl-thio-carbimide in alcohol (Lellmann a. Würthner, *A.* 228, 234). White scales, insol. alcohol, sl. sol. HOAc. Decomposed by heat, giving di-phenyl-thio-urea and a crystalline body [164°].

PHENYL-ETHYLENE-UREA $C_2H_4{<}\begin{matrix}NPh\\NH\end{matrix}{>}CO$. [161°]. Formed from phenyl-ethylene-diamine hydrochloride and potassium cyanate, NH_3 being given off (Newman, *B.* 24, 2192). Plates, v. sol. alcohol, insol. cold water.

Di-phenyl-ethylene-urea $\begin{matrix}CH_2.NPh\\CH_2.NPh\end{matrix}{>}CO$. [209°]. Formed by the action of $COCl_2$ in benzene on $C_2H_4(NHPh)_2$; an intermediate body being $C_{31}H_{28}N_4Cl_2O_3$ (Michler a. Keller, *B.* 14, 2183; Hanssen, *B.* 20, 784). Plates.

PHENYLETHYL-ETHYL-PYRIDINE $C_{15}H_{17}N$ *i.e.* $N{\ll}\begin{matrix}C(CH_2.CH_2Ph).CH\\CH{:}CEt\text{———}CH\end{matrix}$ (316° cor.). S.G. $\frac{0}{4}$ 1·016. Formed by reducing styryl-ethyl-pyridine with HIAq at 165° (Plath, *B.* 21, 3093; 22, 1057). Oil, v. sl. sol. water, v. sol. alcohol and ether, volatile with steam. Yields $C_{15}H_{15}Br_2N$ [128°] whence AgOAc forms $C_{15}H_{15}(OAc)_2N$ (315°-320°). — $B'_2H_2PtCl_6$. [168°]. Yellow needles. — $B'HHgCl_3$. [136°]. Needles. — $B'HAuCl_4$ aq: crystalline mass.

Hexahydride $C_{15}H_{23}N$. (314°). S.G. $\frac{0}{4}$ ·9668. Got by reducing the preceding body in alcohol with Na. Oil, sl. sol. water, miscible with alcohol and ether.

PHENYL-ETHYL-FURFURANE $C_6H_5.CH_2.CH_2.C_4H_3O$. (241°). A product of the action of Na on an alcoholic solution of $C_4H_3O.CH{:}CPh.CN$, which is formed by condensation of furfuraldehyde with phenyl-acetonitrile (Freund a. Immerwahr, *B.* 23, 2848). Oil, smelling like CH_2Ph_2.

DI-PHENYL-ETHYL-GUANIDINE $C_{15}H_{17}N_3$ *i.e.* NHEt.C(NPh).NHPh. Got from phenyl-ethyl-cyanamide and aniline at 100° (Weith, *B.* 8, 1531). Crystalline.—$B'_2H_2PtCl_6$.

PHENYL-ETHYL-HYDANTOÏN $C_{11}H_{12}N_2O_2$ *i.e.* $CHPh{<}\begin{matrix}CO.NEt\\NH.CO\end{matrix}$. [94°]. Formed from phenyl-hydantoïn, alcoholic KOH, and EtI (Pinner, *B.* 21, 2325). Prisms, v. sol. alcohol, sl. sol. cold water. Decomposed by baryta into ethylamine and phenyl-amido-acetic acid.

Phenyl-ethyl-ψ-hydantoïn $CHPh{<}\begin{matrix}CO.NEt\\O-C{:}NH\end{matrix}$. Separates from a dilute alkaline solution of the preceding isomeride on standing. Slender needles, insol. water, nearly insol. alcohol. Decomposed by heating with baryta-water into NH_3, NH_2Et, and α-oxy-phenyl-acetic acid.

***u*-PHENYL-ETHYL-HYDRAZINE** $C_8H_{12}N_2$ *i.e.* $NPhEt.NH_2$. (230°). Formed by reducing the nitrosamine of ethyl-aniline with zinc-dust, HOAc, and alcohol (Fischer, *B.* 8, 1642; *A.* 199, 325; Philips, *B.* 20, 2485). Formed also from EtBr and $NPhNa.NH_2$ in benzene (Michaelis a. Philips, *A.* 252, 270). Oil. Reduces Fehling's solution on warming. Oxidised by HgO to diphenyl-di-ethyl-tetrazone NPhEt.N:N.NPhEt [108°]. $SOCl_2$ forms oily NPhEt.N:SO (Michaelis, *B.* 22, 2231).—B'HCl. Plates.

Acetyl derivative NEtPh.NHAc. [80°].

Ethylo-bromide $NH_2.NPhEt_2Br$. Trimetric prisms (from alcohol); $a{:}b{:}c = ·822{:}1{:}·827$. V. e. sol. water, insol. ether. Decomposes at 193°. Insol. KOHAq. Converted by moist Ag_2O into a caustic hydroxide. Yields also $(NH_2.NPhEt_2)_3H_5Fe_2Cy_{12}\,2aq$ (Fischer, *A.* 190, 187).

Ethylo-chloride $NH_2.NPhEt_2Cl$. [198°]. Needles, v. e. sol. water. $B'_2Et_2PtCl_6$.

Ethylo-iodide $NH_2.NPhEt_2I$. [145°].

***s*-Phenyl-ethyl-hydrazine** NHPh.NHEt. Formed, together with the preceding isomeride, by heating phenyl-hydrazine with EtBr. The crude product is dissolved in water mixed with NaOHAq, and the ppd. oil extracted with ether. The ethereal solution is freed from phenyl-hydrazine by HCl and the filtrate oxidised by HgO. On addition of HCl it deposits di-phenyl-di-ethyl-tetrazone, and the mother-liquor yields by steam-distillation oily $C_6H_5.N{:}NEt$ (175°-185°). The NPh:NEt is then reduced by sodium-amalgam (Ehrhardt a. Fischer, *B.* 11, 613).

Properties.—Oil, sol. alcohol and ether. Readily reduces Fehling's solution and HgO. Zinc-dust and HOAc yield aniline and ethylamine. —$B'H_2C_2O_4$: needles, v. sol. hot water.

DI-PHENYL-ETHYLIDENE-DIAMINE *v.* *Ethylidene-di-aniline*, vol. ii. p. 496.

DI-PHENYL-ETHYLIDENE-DI-ETHYL-DIAMINE $C_{18}H_{24}N_2$ *i.e.* $CHMe(NPhEt)_2$. Formed from ethyl-aniline and aldehyde (Schiff, *A.* 140, 95; *cf.* Schultz, *B.* 16, 2601). Thick liquid.—$B'_2H_2PtCl_6$.

PHENYL-ETHYLIDENE DI-ETHYL DI-SULPHONE $CH_3.CPh(SO_2Et)_2$. [101°]. Formed from benzylidene di-ethyl di-sulphone, MeI, and EtONa (Fromm, *A.* 253, 154). Needles.

PHENYL-ETHYLIDENE-HYDRAZINE $CH_3.CPh{:}N.NH_2$. (255°). Formed from acetophenone and hydrazine hydrate (Curtius, *J. pr.* [2] 44, 540). Liquid. Yields $CH_3.CPh{:}N.N{:}CHPh$ [59°] and $N_2(CPh.CH_3)_2$ [121°].

DI-PHENYL ETHYLIDENE DISULPHONE $CH_3.CH(SO_2Ph)_2$. [102°]. Got by oxidising $CH_3.CH(SPh)_2$ or $CH_3.C(SPh)_2.CO_2H$ with dilute (1 p.c.) $KMnO_4$ (Escales a. Baumann, *B.* 19, 2815). Needles or thin lamellæ, insol. water, acids, and alkalis, sl. sol. alcohol and ether. Not attacked by alcoholic potash at 140°.

PHENYL-ETHYLIDENE-DI-THIO-DI-GLYCOLLIC ACID $CH_3.CPh(S.CH_2.CO_2H)_2$.

[186°]. Got by the action of ZnCl$_2$ on a mixture of acetophenone and thioglycollic acid (Bongartz, *B.* 21, 483). Needles, sol. hot water, CHCl$_3$, and HOAc.

PHENYL-ETHYL-IMESATIN *v. Di-phenyl-di-ethyl-diamide* of ISATIN.

PHENYL ETHYL KETONE $C_9H_{10}O$ *i.e.* $C_6H_5.CO.C_2H_5$. *Propiophenone.* [21°]. (218° cor.) (M. a. G.). V.D. 4·64 (obs.). S.G. ^{0} 1·009 (W.).

Formation.—1. By distilling a mixture of calcium benzoate and propionate (Barry, *B.* 6, 1006). 2. From BzCl and ZnEt$_2$ (Freund, *A.* 118, 20; Kalle, *A.* 119, 166). 3. By the action of Na on a mixture of BzCl and EtI (Bechi, *B.* 12, 463).—4. By the action of propionyl chloride on benzene in presence of AlCl$_3$ (Morley a. Green, *B.* 17, 3018; Pampel a. Schmidt, *B.* 19, 2896).—5. By the decomposition of propylene phenyl-ethyl-ketate by HI or H$_2$SO$_4$ (Morley a. Green).—6. By oxidising CHPhEt.OH (Wagner, *J. R.* 16, 325).—7. From benzoyl cyanide and ZnEt$_2$, either directly or by oxidising the product (Frankland a. Louis, *C. J.* 37, 715).—8. From phenylallylene (Körner, *B.* 21, 277).

Properties.—Tables. Does not combine with NaHSO$_3$. Yields benzoic acid on oxidation. Reduced by sodium-amalgam to CHPhEt.OH (211°).

Oxim CPhEt:NOH. Oil.

Phenyl hydrazide. Oil.

Phenyl ethyl diketone $C_6H_5.CO.CO.C_2H_5$. *Propionyl-benzoyl.* (239°). Got by distilling its mono-oxim (obtained from ethyl benzoyl-acetic ether) with dilute H$_2$SO$_4$ (Müller a. Pechmann, *B.* 22, 2131). Pungent liquid, volatile with steam, m. sol. water.

Reference.—NITRO- and OXY- PHENYL ETHYL KETONE.

PHENYL ETHYL KETONE DIBROMIDE *v.* DI-BROMO-CUMENE.

PHENYL ETHYL KETONE *o*-CARBOXYLIC ACID $C_2H_5.CO.C_6H_4.CO_2H$. *Propionyl-benzoic acid.* [92°]. Formed by boiling phthalyl-propionic acid with KOHAq (Gabriel, *B.* 11, 1014; 19, 840). Needles (from dilute alcohol).—AgA'.

Anhydride  $C_6H_4<\begin{array}{l}C(CHMe)\\CO\text{———}\end{array}>O$. [69°]. Formed by heating phthalic anhydride with succinic acid and NaOAc (G.). Formed also by distilling the anhydride of the dicarboxylic acid (Roser, *B.* 18, 3117). Plates (from water). Combines with N$_2$O$_4$ forming $C_{10}H_8N_2O_6$ [90°].

Amide $C_6H_4(CO.NH_2).CO.C_2H_5$. [159°]. Formed from the anhydride and alcoholic NH$_3$.

Isomerides *v.* BENZOYL-PROPIONIC ACID, vol. i. p. 487.

Phenyl ethyl ketone dicarboxylic acid $C_6H_5.CO.CH_2.CH(CO_2H)_2$. *β-Benzoyl-isosuccinic acid.* [180°]. Obtained by saponifying its ether which is formed from ω-bromo-acetophenone and sodium malonic ether (Bischoff, *B.* 16, 1044; 19, 9[illegible]; Kues a. Paal, *B.* 18, 3321). Needles, v. sol. alcohol and ether. Yields β-benzoyl-propionic acid when heated.—Ag$_2$A'': needles.—Et$_2$A'': oil.

Phenyl hydrazide $C_6H_5.C(N_2HPh).CH_2.CH(CO_2H)_2$. [120°].

Phenyl ethyl ketone dicarboxylic acid $C_6H_4(CO_2H).CO.CH_2.CH_2.CO_2H$. [137°]. Formed by boiling its dilactone with water or aqueous alkalis. Small six-sided prisms, re-converted by heat into the dilactone.—CaA''.—BaA''.—Ag$_2$A''.

Dilactone  $\begin{array}{l}C_6H_4\\CO.O\end{array}>C<\begin{array}{l}CH_2.CH_2\\O.CO\end{array}$. [120°]. A product of the action of phthalic anhydride on succinic acid and NaOAc at 250° (Roser, *B.* 17, 2770; 18, 804, 3115). Needles, sl. sol. cold water. At 260° it gives off CO$_2$ and changes to  $\begin{array}{l}C_6H_4\\CO.O\end{array}>C:CHMe$. HIAq and P at 190° reduce it to $C_6H_4(CO_2H).CH_2.CH_2.CH_2.CO_2H$. Cold NH$_3$Aq forms  $\begin{array}{l}C_6H_4\\CO.NH\end{array}>C:CH.CH_2.CO_2H$ [225°]. Boiling alcoholic NH$_3$ forms $C_{11}H_9NO_4$ [c. 205°]. Sodium-amalgam reduces it to phthalyl-propionic acid $C_{11}H_{10}O_4$. Phenyl hydrazine forms $C_{17}H_{14}N_2O_3$ [210°] which gives CaA'$_2$ aq.

Isomeride *v.* BENZOYL-SUCCINIC ACID.

Phenyl ethyl ketone tetracarboxylic acid $C_6H_4(CO_2H).CO.C(CO_2H)_2.CH_2.CO_2H$. Formed by the action of chloro-acetic ether on $C_{17}H_{19}NaO_7$ which is got from phthalyl-malonic ether and NaOEt (Wislicenus, *A.* 212, 58). Oil.—Ag$_4$A^{IV}.

PHENYLETHYL METHYL KETONE *v.* BENZYL-ACETONE.

Diphenylethyl methyl ketone $CH_3.CPh_2.CO.CH_3$. [41°]. (311° i.V.). A product of the action of zinc and HCl on an alcoholic solution of acetophenone (Zincke a. Thörner, *B.* 11, 1989). Prisms (from alcohol).

PHENYLETHYL-METHYL-PYRIDINE $C_{14}H_{15}N$ *i.e.* $C_2H_4Ph.C_5H_3MeN$. (290°–295°). S.G. $\frac{0}{4}$ 1·0283. Formed by reducing styryl-methyl-pyridine with HIAq at 160° (Bachér, *B.* 21, 3076). Oil, volatile with steam. $B'_2H_2PtCl_6$. [168°].—$B'HHgCl_3$ aq. [95°]. Silky needles.—$B'C_6H_3N_3O_7$. [156°]. Yellow needles

Hexahydride $C_{14}H_{21}N$. (c. 288°). S.G. $\frac{0}{4}$ ·9775. Got by reducing styryl-methyl-pyridine in alcohol with Na. Liquid, v. sl. sol. water.

PHENYL-ETHYL-(β)-NAPHTHOTRIAZINE DIHYDRIDE $C_{19}H_{17}N_3$ *i.e.*  $C_{10}H_6<\begin{array}{l}N:CHEt\\N:NPh\end{array}$ [219°]. Formed by adding propionic aldehyde to benzene-azo-(β)-naphthylamine in alcohol (Goldschmidt a. Poltzer, *B.* 21, 1006). White needles, v. sol. alcohol. B'HCl. [258°].—$B'_2H_2PtCl_6$. Small yellow crystals.

PHENYL-ETHYL-OXAMIDE $C_{10}H_{12}N_2O_2$ *i.e.* NHPh.CO.CO.NHEt. [170°]. Formed by the action of ethylamine on phenyloxamic ether or of aniline on ethyloxamic ether (Wallach, *A.* 184, 66; 214, 259). Needles (from alcohol). Converted by PCl$_5$ (2 mols.) into a base which forms the salt $(C_{10}H_9N_2Cl)_2H_2PtCl_6$.

Di-phenyl-di-ethyl-oxamide *v.* vol. iii. p. 654.

PHENYL-ETHYL-PHENOL *v.* OXY-DI-PHENYL-ETHANE.

PHENYL-*p*-ETHYL-PHENYL-ETHANE $C_6H_5.CH_2.CH_2.C_6H_4.C_2H_5$. (294°). Formed by reduction of $C_6H_5.CH_2.CO.C_6H_4Et$ with HI and P (Söllscher, *B.* 15, 1681). Liquid.

Isomeride. Got by the action of zinc-dust on a mixture of ethyl-benzene and α-bromo-ethyl-benzene (Radziszewski, *B.* 6, 811; 7, 140). Gives *p*-benzoyl-benzoic acid on oxidation.

PHENYL-ETHYLPHENYL-ETHYLENE $C_6H_5.CH:CH.C_6H_4Et$. [90°]. Formed by boiling $CH_2Ph.CH(OH).C_6H_4Et$[1:4] with dilute H$_2$SO$_4$ (Söllscher, *B.* 15, 1681). Plates.

PHENYL *p*-ETHYLPHENYL KETONE $C_6H_5.CO.C_6H_4Et$. (331°) at 720 mm. Prepared by the action of $AlCl_3$ on a mixture of BzCl and ethylbenzene (Söllscher, *B.* 15, 1682; Smith, *B.* 24, 4029). Liquid, sol. alcohol and ether. Yields two oxims [108°] and [142°], both giving the same acetyl derivative [95°].

PHENYL-ETHYL-PHENYL METHANE *v.* BENZYL-ETHYL-BENZENE.

PHENYL - ETHYLPHENYL - THIO - UREA $NHPh.CS.NH.C_6H_4Et$. [104°]. Formed from *p*-ethyl-phenyl-thiocarbimide and aniline in alcohol (Mainzer, *B.* 16, 2020). Plates.

PHENYL-DI-ETHYL-PHOSPHINE $PEt_2C_6H_5$. (222° cor.). S.G. ^{13} ·957. Formed from $C_6H_5PCl_2$ and $ZnEt_2$ (Michaelis, *B.* 8, 493; *A.* 181, 345). Oil. Absorbs oxygen from air, yielding $OPEt_2C_6H_5$ [56°]. Combines also with Cl and S forming crystalline $C_{10}H_{15}PCl_2$ and $C_{10}H_{15}PS$. — $B'2HCl$. — $B'_2H_2PtCl_6$. — $B'HI$. — $B'EtI$. [115°]. — $B'_2Et_2PtCl_6$. — $B'MeI$. [95°]. — $B'_2Me_2PtCl_6$.

Di-phenyl-ethyl-phosphine $PEtPh_2$. (298°). Formed from Ph_2PCl and $ZnEt_2$ (Michaelis a. Link, *A.* 207, 214). Liquid, sol. alcohol and ether. Yields $OPEtPh_2$ on oxidation. EtI yields Ph_2PEt_2I [204°] which gives $(Ph_2PEt_2Cl)_2PtCl_4$ [218°]. MeI gives $Ph_2PEtMeI$ [181°] S. 1·5 at 22°; 50 at 100°, which gives $(Ph_2PEtMeCl)_2PtCl_4$ [220°] and $Ph_2PEtMe.O.C_6H_2(NO_2)_3$ [86°].

Di-phenyl-ethyl-phosphine oxide $PEtPh_2O$. [121°]. Formed as above, and also by the action of Ag_2O on Ph_3PEtI (Michaelis a. Soden, *A.* 229, 317). Prisms, sol. ether and ligroïn.

PHENYL-DI-ETHYL PROPENYL TRISULPHONE $PhSO_2CH_2.CMe(SO_2Et)_2$. [128°]. Got from EtSH and $PhS.CH_2.CO.CH_3$, the product being oxidised (Autenrieth, *B.* 24, 169). Plates.

Di-phenyl ethyl propenyl trisulphone $EtSO_2.CH_2.CMe(SO_2Ph)_2$. [139°]. Made in like manner from PhSH and $EtS.CH_2.CO.CH_3$. Needles (Autenrieth, *B.* 24, 1513).

TRI - PHENYL - ETHYL - PROPYL - DI - THIO - BIURET $C_2S_2N_3Ph_3EtPr$. The (α)- compound [166°] is formed by the action of di-phenyl-propyl-thio-urea on ClCS.NPhEt, while the (β)-compound [165°] is got from di-phenyl-ethyl-thio-urea and ClCS.NPhPr (Billeter a. Strohl, *B* 21, 109). Both crystallise in needles, v. sol. hot alcohol.

DI - PHENYL - ETHYL - PROPYL - THIO - UREA NPhEt.CS.NPhPr. [66°]. Formed by the action of $CSCl_2$ on propyl-aniline followed by ethyl-aniline or *vice versâ* (Billeter a. Strohl, *B.* 21, 103).

PHENYL-ETHYL-PYRAZOLE $C_{11}H_{12}N_2$ *i.e.*

$NPh{<}\begin{matrix}CEt{:}CH\\ N{=}CH\end{matrix}$. (274°). S.G. ^{15} 1·064. Formed from phenyl-hydrazine and propionyl-acetic aldehyde (Claisen a. Stylos, *B.* 21, 1148). Oil.

PHENYLETHYL-PYRIDINE

$CH{<}\begin{matrix}CH{:}CH\\ CH.N\end{matrix}{>}C.CH_2.CH_2Ph$. [−3°]. (289° cor.). S.G. $\frac{0}{4}$ 1·0465. Formed by reducing styryl-pyridine with HI (Baurath, *B.* 21, 821). Liquid, sl. sol. water, volatile with steam. — $B'_2H_2PtCl_6$. [186°]. — $B'HAuCl_4$. [150°]. Long yellow needles. — $B'HHgCl_3$. [149°].

Hexahydride $C_{13}H_{19}N$. (288° cor.). S.G. $\frac{0}{4}$ ·9874. Got by reducing the preceding base in alcohol with Na. Liquid, smelling like piperidine, sl. sol. water. Turns moist litmus blue. Has toxic properties similar to those of coniine. Forms an oily nitrosamine. Yields pyridine carboxylic acid on oxidation. — $B'HCl$. [155°]. — $B'_2H_2PtCl_6$. [189°]. — $B'HAuCl_4$. [134°].

TETRA-PHENYL-ETHYL-PYRROLE

$NEt{<}\begin{matrix}CPh{:}CPh\\ CPh{:}CPh\end{matrix}$. [221°]. Formed by heating bidesyl with aqueous $NEtH_2$ at 150° (Fehrlin, *B.* 22, 555). Needles (from chloroform) or plates (from HOAc).

DI-PHENYL-ETHYL-PYRROLE DI-*o*-CARBOXYLIC ACID $C_{20}H_{17}NO_4$ *i.e.*

$NEt{<}\begin{matrix}C(C_6H_4.CO_2H){:}CH\\ C(C_6H_4.CO_2H){:}CH\end{matrix}$. [220°]. Formed by heating $C_2H_4(CO.C_6H_4.CO_2H)_2$ with ethylamine solution (Baumann, *B.* 20, 1488). Yellow plates (from alcohol), insol. water. — Ag_2A''.

PHENYLETHYL-QUINOLINE

$C_6H_4{<}\begin{matrix}CH{:}CH\\ N{=}C.CH_2.CH_2Ph\end{matrix}$. [c. 30°]. Formed by reducing styryl-quinoline with HI (Heymann a. Königs, *B.* 21, 1426). Crystals. — Picrate. [c. 130°]. Yellow prisms, sl. sol. alcohol.

PHENYL-ETHYL SULPHIDE Ph.S.Et. (204° i.V.) at 744 mm. S.G. ^{19} :1·032. Formed by heating PhSNa with EtI in sealed tubes at 120° (Beckmann, *J. pr.* [2] 17, 457). Obtained also by the action of H_2S at 50° on $C_6H_5.SO.OEt$ (Otto a. Rössing, *B.* 20, 2275) and by the action of EtSH on $C_6H_5.N_2Cl$ (Stadler, *B.* 17, 2078). Liquid, with nasty smell.

Sulphonic acid $C_2H_5.S.C_6H_4.SO_3H$. Formed by boiling $C_2H_5S.N_2.C_6H_4.SO_3Na$ with alcohol. — NaA′: plates.

Phenyl ethyl disulphide PhS_2Et. Formed together with Et_2S_2 by heating $C_6H_5SO_2H$ with EtSH at 100° (Otto a. Rössing, *B.* 19, 3135; 20, 189). Heavy oil. Decomposed by alcoholic potash into EtSH, Ph_2S_2, $C_6H_5SO_2H$, and ethane sulphinic acid.

PHENYL ETHYL SULPHONE $C_8H_{10}SO_2$ *i.e.* $C_6H_5.SO_2.C_2H_5$. [43°]. (above 300°). Formed from $C_6H_5SO_2Na$ and EtBr or $CH_3.CBr_2.CO_2Na$ (Otto, *B.* 13, 1274; *J. pr.* [2] 40, 535). Formed also from $CH_3.CH(SO_2Ph).CO_2H$ by the action of alkalis and by oxidising PhSEt with dilute $KMnO_4$ (Beckmann, *J. pr.* [2] 17, 458). Monoclinic plates (Fock, *B.* 19, 1230), sol. hot water, v. sol. alcohol.

α-Carboxylic acid $C_6H_5.SO_2.CHMe.CO_2H$. *Phenyl sulphono-propionic acid.* [116°]. Formed by saponifying its ether, which is got from $C_6H_5SO_2Na$ and $CH_3.CHBr.CO_2Et$ (Otto, *J. pr.* [2] 40, 548). Groups of needles, v. sol. hot water. — NaA′. — BaA'_2 2aq: leafy aggregates.

Ethyl ether EtA′. [c. 17°]. Oil.

β-Carboxylic acid $C_6H_5.SO_2.CH_2.CH_2.CO_2H$. [124°]. Formed from benzene sulphinic acid and β-iodo-propionic acid (Otto, *B.* 21, 95). Plates, sl. sol. cold water, m. sol. ether.

PHENYL-ETHYL-THIAZOLE $C_{11}H_{11}NS$ *i.e.*

$N{<}\begin{matrix}CEt.S\\ CPh{:}CH\end{matrix}$. (296° cor.). Formed from thio-propionamide and bromo-acetophenone in alcohol (Hubacher, *A.* 259, 231). Oil. — $B'_2H_2PtCl_6$. [129°]. — B′HBr. [70°]. White needles.

TRI-PHENYL-DI-ETHYL-DI-THIO-BIURET NPhEt.C(NPh).S.CS.NPhEt. [158°]. Formed from NPhEt.CS.Cl (2 mols.) and aniline (1 mol.)

Billeter a. Strohl, *B.* 21, 108). Yellow needles, l. sol. alcohol.

PHENYL-ETHYL-THIOCARBAMIC ACID NPhEt.CS.OH.

Ethyl ether EtA. [18°]. (143° at 12 mm.). S.G. ^{15} 1·066. Formed from NPhEt.CS.Cl nd NaOEt (Billeter a. Strohl, *B.* 20, 1629; 21, 04). Crystals.

Phenyl-ether PhA′. [69°]. Formed from he chloride and phenol. Flat needles.

Chloride NPhEt.CS.Cl. [57°]. Formed rom ethyl-aniline and $CSCl_2$. Prisms (from igroïn). Converted by alcohol into $(NPhEt.CS)_2O$ 143°], S. (alcohol) 7 at 15°.

Phenylethyl-thiocarbamic acid. Phenyl-thylamine salt $C_2H_4Ph.NH.CS.SNH_3.C_2H_4Ph$ [130°]. Formed rom phenylethylamine and CS_2 (Neubert, *B.* 19, 825). Sol. hot water and alcohol.

Phenyl-ethyl-di-thio-carbamic acid NPhEt.CS.SH.

Ethyl ether EtA′. [67°]. (305°–315°). Formed by heating NPh:C(NPhEt).SEt with CS_2 at 160° (Bernthsen a. Friese, *B.* 15, 568, 533). Formed also from NPhEt.CSCl and NaSEt (B. a. S.). Prisms (from ether). Forms a crystalline compound with MeI.

Phenyl ether PhA′. [127°]. Formed from NPhEt.CS.Cl and PhSH (B. a. S.). Needles.

PHENYL-ETHYL-THIO-SEMI-CARBAZIDE NHEt.CS.NH.NHPh. [122°]. Formed from ethyl-thiocarbimide and phenyl-hydrazine (Dixon, *C. J.* 55, 302). White crystals, v. sl. sol. water. $FeCl_3$ gives a red colour changing to blackish-green.

Isomeride NHPh.CS.NH.NHEt. [110°]. Formed from phenyl-thiocarbimide and ethyl-hydrazine (Fischer, *A.* 199, 296). Needles.

Di-phenyl-ethyl-thio-semi-carbazide NPhEt.NH.CS.NHPh. [149°]. Formed from α-phenyl-ethyl-hydrazine and phenyl-thiocarbimide (Michaelis a. Philips, *A.* 252, 273).

PHENYLETHYL-THIOCARBIMIDE $C_2H_4Ph.NCS$. Formed from phenylethyl-amine by successive treatment with CS_2 and $HgCl_2$ (Neubert, *B.* 19, 1825). Yellow oil.

PHENYL ETHYL DITHIOCARBONATE CS(OEt)(SPh). Formed by mixing solutions of $C_6H_5.N_2Cl$ and potassium ethyl dithiocarbonate at 0° (Leuckart, *J. pr.* [2] 41, 186). Reddish-yellow oil, sl. sol. water, slightly volatile with steam. Converted by heating with alcoholic NH_3 into phenyl mercaptan and ammonium sulphocyanide.

PHENYLETHYL-THIOHYDANTOÏN

$C_{11}H_{12}N_2SO$ *i.e.*

$C_2H_4Ph.N:C\left<\begin{matrix}S-CH_2\\NH.CO\end{matrix}\right.$ or

$CS\left<\begin{matrix}N(C_2H_4Ph).CH_2\\NH\text{——}CO\end{matrix}\right.$. The hydrochloride B′HCl [138°] is formed from phenylethyl-thio-urea and chloro-acetic acid (Neubert, *B.* 19, 1822).

PHENYL-ETHYL-THIOPHENE $C_{12}H_{12}S$ *i.e.*

$S\left<\begin{matrix}CPh:CH\\CH:CEt\end{matrix}\right.$ [40°]. Obtained by heating $CH_2Bz.CHEt.CO_2Na$ with P_2S_5 (Dittrich a. Paal, *B.* 21, 3457). Small plates. Gives a cherry-red colour with isatin and H_2SO_4 and a bluish-green colour with phenanthraquinone and HOAc.

u-PHENYL-ETHYL-THIO-UREA $C_9H_{12}N_2S$ i.e. $NPhEt.CS.NH_2$. [1[illegible]8°]. Formed from ethyl-aniline hydrochloride and potassium sulphocyanide (Gebhardt, *B.* 17, 2094). Large pearly prisms (from alcohol).

Benzoyl derivative NPhEt.CS.NHBz. [134°]. Formed from ethylaniline and benzoyl-thiocarbimide (Dixon, *C. J.* 55, 305). Pale lemon-yellow prisms, insol. water, sol. alcohol.

s-Phenyl-ethyl-thio-urea NHPh.CS.NHEt. [99°]. Formed from phenyl-thiocarbimide and NH_2Et and from ethyl-thiocarbimide and aniline (Weith, *B.* 8, 1524; Michael a. Palmer, *Am.* 6, 260). Monoclinic crystals.

Phenylethyl-thio-urea $NH_2.CS.NH.C_2H_4Ph$. [123°]. Formed from phenylethyl-amine hydrochloride and potassium sulphocyanide (Neubert, *B.* 19, 1822). Plates (from dilute alcohol).

Phenyl-ethyl-ψ-thio-urea NHPh.C(SEt):NH. Formed from phenyl-thio-urea and EtI (Bertram, *B.* 25, 55). Yields mercaptan on treatment with alkalis.—B′HI. [103°].—$B'C_6H_3N_3O_7$. [196°].

Phenyl-di-ethyl-ψ-thio-urea NPhEt.C(SEt):NH. Formed from the preceding body and EtI (B.).—B′HI.—$B'_2H_2PtCl_6$. [148°].—$B'C_6H_3N_3O_7$. [170°].

Phenyl-tri-ethyl-ψ-thio-urea NPhEt.C(SEt):NEt. (c. 275°). Got from the preceding and EtI (B.).—$B'C_6H_3N_3O_7$. [c. 96°].—$B'_2H_2PtCl_6$. [135°].

Di-phenyl-ethyl-thio-urea NHPh.CS.NPhEt. [89°]. Formed from phenyl-thiocarbimide and ethyl-aniline (Gebhardt, *B.* 17, 2090). Crystals.

Di-phenyl-ethyl-ψ-thio-urea NHPh.C(SEt):NPh. [79°]. Formed from di-phenyl-thio-urea and EtBr (Rathke, *B.* 14, 1776) and by the action of mercaptan on $C(NPh)_2$ in the cold (Will, *B.* 15, 1308). Needles (from dilute alcohol). Decomposed by heat into $C(NPh)_2$ and EtSH. Cl passed into a solution of its hydrochloride yields ethane sulphonic acid. B′HCl.—$B'_2H_2PtCl_6$2aq.—B′HI aq. [157·5°] (Bernthsen, *B.* 15, 266, 567).

Di-phenyl-di-ethyl-thio-urea $CS(NEtPh)_2$. [75·5°]. Formed from NPhEt.CSCl and ethyl-aniline at 100° (Billeter, *B.* 20, 1631). White tables (from ligroin) or needles (from alcohol).

Di-phenyl-di-ethyl-thio-urea $CS(NH.C_2H_4Ph)_2$. [84°]. Formed from phenyl-ethyl-amine and alcoholic CS_2 (Neubert, *B.* 19, 1824). Plates (from alcohol), insol. water.

Acetyl derivative $C_{19}H_{22}N_2SO$. [73°].

Di-phenyl-di-ethyl-ψ-thio-urea NPhEt.C(SEt):NPh. Oil. The hydro-iodide, got by heating di-phenyl-ethyl-ψ-thio-urea with EtI at 130°, is crystalline (B. a. F.).

u-PHENYL-ETHYL-UREA $NPhEt.CO.NH_2$. [62°]. Formed from ethyl-aniline hydrochloride and potassium cyanate (Gebhardt, *B.* 17, 2095).

s-Phenyl-ethyl-urea NPhH.CO.NEtH. [99°]. Formed from ethyl cyanate and aniline (Wurtz, *C. R.* 32, 417). Needles (from dilute alcohol). Yields a nitrosamine NPhH.CO.NEt.NO [60°] crystallising in monoclinic prisms (E. Fischer, *A.* 199, 286).

Phenylethyl-urea $NH_2.CO.NHC_2H_4Ph$. [112°]. Formed from β-phenyl-ethyl-amine and potassium cyanate (Spica, *G.* 9, 568). Flat prisms, m. sol. cold water.

Phenyl-di-ethyl-urea $NHPh.CO.NEt_2$. [85°]. Formed from phenyl cyanate and $NHEt_2$ (Gebhardt, *B.* 17, 3039). Needles.

Di-phenyl-ethyl-urea NHPh.CO.NPhEt. [91°]. Got from phenyl cyanate and ethyl-aniline (Gebhardt, *B.* 17, 2093). Prisms.

s-**Di-phenyl-di-ethyl-urea** $CO(NPhEt)_2$. [79°]. Formed from NPhEt.COCl and ethyl-aniline at 130° (Michler, *B.* 9, 712). Crystals.

u-**Di-phenyl-di-ethyl-urea** $NPh_2.CO.NEt_2$. [54°]. Formed from $NPh_2.COCl$ and $NHEt_2$.

Diphenyldiethyl-urea $NH_2.CO.N(C_2H_4Ph)_2$. [109°]. Formed from diphenyldiethylamine hydrochloride and potassium cyanate in aqueous solution (Spica, *G.* 9, 568). Prisms, sol. hot Aq.

Tri-phenyl-ethyl-urea $NPh_2.CO.NPhEt$. [89°]. Formed from NPh_2COCl and ethyl-aniline (M.). Formed also from NPhEt.COCl and diphenylamine (Kaufmann, *B.* 14, 2185).

PHENYL-FORMAMIDE *v.* vol. ii. p. 568.

DI-PHENYL-FORMAMIDINE $C_{13}H_{12}N_2$ *i.e.* CH(NPh)(NHPh). *Di-phenyl-methenyl-diamine.* Mol. w. 196. [138°].

Formation.—1. By heating chloroform with aniline for 12 hours at 190° (Hofmann, *Pr.* 9, 229).—2. By heating aniline with phenyl-carbamine, with orthoformic ether, or with formic acid (Weith, *B.* 9, 454; Wichelhaus, *B.* 2, 116).—3. By passing gaseous HCl into heated formic anilide (Wallach, *B.* 15, 208).—4. From formic anilide and PCl_5 (Wallach, *A.* 214, 233). 5. From CH(NPh)SEt and aniline (Wallach a. Wüsten, *B.* 16, 146).—6. From aniline and $CH(NH_2Cl)OEt$ (Pinner, *B.* 16, 358).

Properties.—Needles (from ether). Yields B'HCl and $B'_2H_2PtCl_6$.

PHENYL-FORMAMIDOXIM C_7H_8NO *i.e.* CH(NOH).NHPh. [116°]. Formed from thio-formanilide and hydroxylamine (Müller, *B.* 22, 2411). Needles, m. sol. water.—B'HCl: needles.—$B'_2H_2PtCl_6$: yellow needles.

Benzoyl-derivative CH(NOBz)(NHPh). [145°]. Needles, m. sol. alcohol and ether.

DI-PHENYL-FORMAZIDINE $C_{13}H_{14}N_4$ *i.e.* $CH(N_2HPh).N_2H_2Ph$. [185°]. Formed from $CH(NH_2Cl).OEt$ and phenyl-hydrazine (Pinner, *B.* 17, 2002). Yellow plates, v. sol. hot alcohol.

PHENYL-FORMYLACETIC ETHER $CHO.CHPh.CO_2Et$. (145° at 16 mm.). Got, together with an isomeride [71°], by the action of NaOEt on a mixture of formic and phenyl-acetic ethers (Wislicenus, *B.* 20, 2931). Liquid. $FeCl_3$ colours its alcoholic solutions bluish-violet. Phenyl-hydrazine forms oxy-di-phenyl-pyrazole.

DI-PHENYL-FUMARAMIC ACID *v.* FUMARIC ACID.

PHENYL-FUMARIC ACID $C_{10}H_8O_4$ *i.e.* $CO_2H.CPh:CH.CO_2H$. [161°]. Got by heating bromo-cinnamic ether with alcoholic KCy for 8 hours at 150° (Barisch, *J. pr.* [2] 20, 186). Got also by heating $CO_2H.CPh(OH).CH_2.CO_2H$ (Alexander, *A.* 258, 82). Nodules (from water).—BaA'': scales.—Ag_2A'': amorphous pp.

Di-phenyl-fumaric acid $CO_2H.CPh:CPh.CO_2H$. [c. 260°]. Formed from its ether, which is got, together with di-phenyl-maleïc ether, by the action of Na on α-bromo-phenyl-acetic ether (Rügheimer, *B.* 15, 1626). Crystals, decomposing at 260° into water and di-phenyl-maleïc anhydride.

Nitrile CN.CPh:CPh.CN. [158°]. Got by adding alcoholic NaOEt to α-chloro-phenyl-acetonitrile (Michael a. Jeanprêtre, *B.* 25, 1680).

DI-PHENYL FURAZANE $\begin{matrix}CPh{:}N\\CPh{:}N\end{matrix}{>}O$. [94°] Formed by heating the (α)-di-oxim of benzil with water at 210° (Dodge, *A.* 264, 180). Crystals At 300° it forms di-benzenyl-azoxim. H_2SO_4 and HNO_3 give a di-nitro derivative [220°].

DI-PHENYL-FURFURANE $\begin{matrix}CH{:}CPh\\CH{:}CPh\end{matrix}{>}O$. [91°]. (345°). Formed by heating $CPh{:}C.CH(CO_2H).CO.C_6H_5$ or $CH_2Bz.CH_2Bz$ with conc. HClAq at 160° for 3 hours (Kapf a. Paal, *B.* 21, 1490, 3057). Got also by heating its dicarboxylic acid (W. H. Perkin, jun., a. Schlosser, *C. J.* 57, 954). Plates, insol. water.

Tetrahydride $C_{16}H_{16}O$. (321°). Got by reducing with Na and alcohol. Oil.

Octohydride $C_{16}H_{20}O$. Oil.

Tri-phenyl-furfurane $C_{22}H_{16}O$ *i.e.* $\begin{matrix}CPh{:}CH\\CPh{:}CPh\end{matrix}{>}O$. [93°]. Mol. w. 263 by Raoult's method (calc. 296). Formed by boiling CPhBz:CHBz with HIAq (Japp a. Klingemann, *C. J.* 57, 675). Got also from desyl-acetophenone by successive treatment with H_2SO_4 and water (Smith, *C. J.* 57, 645). Needles (from alcohol).

Tetra-phenyl-furfurane *v.* LEPIDEN.

DI-PHENYL-FURFURANE CARBOXYLIC ACID $\begin{matrix}CO_2H.C{:}CPh\\HC{:}CPh\end{matrix}{>}O$. [217°]. Formed by boiling $CPh{:}C.CHBz.CO_2H$ with conc. HClAq and alcohol (Kapf a. Paal, *B.* 21, 1489, 3059). Formed also by heating the dicarboxylic acid (W. H. Perkin, jun., a. Schlosser, *C. J.* 57. 952). Needles (from alcohol), insol. water. May be distilled. Br yields $C_{17}H_{12}Br_4O_3$.—NaA': needles.

Ethyl ether EtA'. [82°]. Formed by boiling $CH_2Bz.CHBz.CO_2Et$ with alcohol and HClAq. Crystals (from ether). Yields on reduction a tetrahydride which does not react with AcCl.

Di-phenyl-furfurane dicarboxylic acid $C_{18}H_{12}O_5$ *i.e.* $\begin{matrix}CO_2H.C{:}CPh\\CO_2H.C{:}CPh\end{matrix}{>}O$. [23[illegible]°]. Formed by dissolving di-benzoyl-succinic ether in H_2SO_4 and boiling the product with alcoholic potash (W. H. Perkin, jun., *C. J.* 47, 262; 49, 168; 57, 951). Needles, sol. alcohol and ether. $FeCl_3$ gives an orange colour in its alcoholic solution. Yields acetophenone on distilling with soda-lime.—Ag_2A''.

Ethyl ether Et_2A''. [86°]. Formed from dibenzoyl-succinic acid and H_2SO_4. Yellow prisms, v. sol. alcohol. Its solution in H_2SO_4 turns violet on heating.

Anhydride $C_{18}H_{10}O_4$. [255°]. Formed by heating the acid alone or with Ac_2O. Plates, sl. sol. hot alcohol. Its alcoholic solution exhibits violet fluorescence.

PHENYL-FURFURYL-ACRYLIC ACID. *Nitrile.* $C_4H_3O.CH{:}CPh.CN$. [43°]. Formed from phenyl-acetonitrile, furfuraldehyde, and NaOEt in alcohol (Frost, *A.* 250, 159). Yields $C_4H_3O.CHBr.CBrPh.CN$ [114°] crystallising in orange plates.

Reference.—NITRO-PHENYL-FURFURYL-ACRYLIC ACID.

PHENYL-FURFURYL-(β)-NAPHTHO-TRIAZINE. *Dihydride* $C_{21}H_{15}N_3O$ *i.e.* $C_{10}H_6{<}\begin{matrix}N.CH.C_4H_3O\\N.NPh\end{matrix}$. [241°]. Formed by warming benzene-azo-(β)-naphthylamine with furfuraldehyde in alcohol (Goldschmidt a. Poltzer, *B.* 24, 1007). Needles.—B'HCl: plates.—$B'_2H_2PtCl_6$. Light-yellow crystalline pp.

(β)-**PHENYL-(γ)-FURFURYL-PROPYL-AMINE** $C_4H_3O.CH_2.CHPh.CH_2NH_2$. (283°). Formed from phenyl-acetonitrile and furfuraldehyde, the product of condensation of these bodies $C_4H_3O.CH{:}CPh.CN$ being reduced by Na and dry alcohol (Freund a. Immerwahr, *B.* 23, 2850). Oil, with alkaline reaction. Converted by nitrous acid into the liquid alcohol $C_4H_3O.CH_2.CHPh.CH_2OH$. Phenyl thiocarbimide forms $C_4H_3O.C_3H_5Ph.NH.CS.NHPh$ [113°].—B'HCl. [176°]. Crystalline, v. sol. water. Reacts with potassium cyanate forming $C_4H_3O.C_3H_5Ph.NH.CO.NH_2$ [101°].—Mercury double salt: [175°]; needles.—Picrate [152°]. Yellow crystalline powder.

PHENYL-FURIDANE. *Dihydride*  $\mathrm{CPh}<\begin{matrix}\mathrm{CH.CH_2}\\ \mathrm{O-CH_2}\end{matrix}>\mathrm{CH_2}$. (250° at 721 mm.). Formed by heating its carboxylic acid at 200° (Perkin, *C. J.* 51, 731). Oil. HBr forms $C_6H_5.CO.C_4H_8Br$.

PHENYL-FURIDANE DIHYDRIDE CARBOXYLIC ACID $\mathrm{CO_2H.C}<\begin{matrix}\mathrm{CH_2.CH_2}\\ \mathrm{CPh.O}\end{matrix}>\mathrm{CH_2}$. *Phenyldehydrohexone carboxylic acid.* [c. 144°]. Formed by saponifying its ether, which is got by the action of NaOEt on a mixture of trimethylene bromide and benzoyl-acetic ether (Perkin, *C. J.* 51, 726). Monoclinic prisms (from ether); *a*:*b*:*c* = 2·638:1:3·398; β = 74° 44'.—AgA': needles (from water).

Ethyl ether EtA'. [60°]. Prisms.

PHENYL-GLUTARIC ACID $C_{11}H_{12}O_4$ *i.e.* $CHPh(CH_2.CO_2H)_2$. [138°]. Formed by heating sodium malonic ether with alcohol and cinnamic ether at 100°, saponifying the resulting ether $CH(CO_2Et)_2.CHPh.CHNa.CO_2Et$, and heating the acid at 110° (Michael, *J. pr.* [2] 35, 352; *Am.* 9, 116). Needles, sl. sol. water, m. sol. alcohol.—AgA': amorphous pp.

Di-phenyl-glutaric acid $CH_2(CHPh.CO_2H)_2$. [164°]. Formed by saponifying its nitrile (Zelinsky a. Feldmann, *B.* 22, 3292). Needles.

Nitrile $CH_2(CHPh.CN)_2$. [71°]. Formed by heating $CH_2Ph.CN$ with CH_2I_2 and dry NaOH.

PHENYL-GLYCERIC ACID *v.* DI-OXY-PHENYL-PROPIONIC ACID.

TRI-PHENYL GLYCERYL TRIKETONE $CH_2Bz.CHBz.CH_2Bz$. *Tri-benzoyl-propane.* [137°]. Formed from tricarballylic chloride, benzene, and $AlCl_3$ (Emery, *B.* 21, 601). Straw-yellow needles. Yields a phenyl-hydrazide [57°–60°].

PHENYL-GLYCIDIC ACID $C_9H_8O_3$ *i.e.*  $\mathrm{O}<\begin{matrix}\mathrm{CHPh}\\ \mathrm{CH.CO_2H}\end{matrix}$. *Phenyl-pyruvic acid?* [155°] Formed by boiling benzoyl-imido-phenyl-propionic acid $\mathrm{NBz}<\begin{matrix}\mathrm{CHPh}\\ \mathrm{CH.CO_2H}\end{matrix}$ with aqueous HCl or with KOH (Plöchl, *B.* 16, 2817; 19, 3167). Formed also by boiling phenyl-oxalacetic acid with dilute H_2SO_4 (W. Wislicenus, *B.* 20, 592). Plates, v. e. sol. alcohol and ether. $FeCl_3$ colours its alcoholic solution green. Sodium-amalgam reduces it to α-oxy-phenyl-propionic acid. Yields an oxim and a phenyl-hydrazide $CH_2Ph.C(N_2HPh)CO_2H$ [161°]. Tolylene-*o*-diamine forms a quinoxaline (Erlenmeyer, jun., *B.* 19, 2576; 20, 2465; 22, 1482). Aniline forms $C_2H_2Ph(NHPh)(OH).CO_2H$.

(β)-Phenyl-glycidic acid. Formed from $C_6H_5.CH(OH).CHCl.CO_2H$ and cold alcoholic potash (Glaser, *A.* 147, 98). Oil, crystallising at 0°. Decomposes, even at 15°, into phenyl-acetic aldehyde and CO_2. Boiling dilute H_2SO_4 forms $CHPh(OH).CH(OH).CO_2H$ and phenyl-acetic aldehyde (Erlenmeyer a. Lipp, *A.* 219, 181). Yields β-oxy-phenyl-propionic acid on reduction with sodium-amalgam.—NaA'.—KA'.—AgA': crystalline powder.

Ethyl ether EtA'. (280° cor.). Oil.

References.—NITRO- and OXY- PHENYL-GLYCIDIC ACID.

PHENYL-GLYCOCOLL *v.* PHENYL-AMIDO-ACETIC ACID.

PHENYL-GLYCOL *v.* DI-OXY-ETHYL-BENZENE.

PHENYL-GLYCOLLIC ACID *v. Phenyl-derivative* of GLYCOLLIC ACID and MANDELIC ACID.

Di-phenyl-glycollic acid *v.* BENZILIC ACID.

PHENYL-GLYCOLLIC ACRYLIC ACID *v. Carboxy-methyl derivative* of COUMARIC ACID.

PHENYLGLYCOLYL-TROPEÏNE $C_{16}H_{21}NO_3$. *Homo-atropine.* [98°]. Formed by heating tropine mandelate with HClAq (Ladenburg, *A.* 217, 82). Deliquescent prisms (from ether), m. sol. water. Less poisonous than atropine.—$B'HAuCl_4$.—B'HBr.—$B'C_6H_3N_3O_7$. Yellow plates.

TETRA-PHENYL-GLYCOSINE *v.* GLYCOSINE.

PHENYL-GLYOXAL $C_6H_5.CO.CHO$. (142° at 125 mm.). Formed by allowing a mixture of its mono-oxim (30 g.) with $NaHSO_3$ (120 g. of a 35 p.c. solution) to stand till all is dissolved, and then adding H_2SO_4 and distilling (Müller a. von Pechmann, *B.* 20, 2904; 22, 2557). Oil. Forms a crystalline hydrate [73°]. Converted by HNO_3 into phenyl-glyoxylic acid, and by potash into mandelic acid. Ammonia forms $C_{22}H_{19}N_3O$ or $C_{22}H_{17}N_3O$ crystallising in plates [193°] which can be distilled. Hydroxylamine gives $C_{16}H_{13}N_3O_3$, [219°], sol. alkalis.

Mono-oxim $C_6H_5.CO.CH{:}NOH$. *Nitroso-acetophenone.* [128°]. Formed from acetophenone, isoamyl nitrite, and alcoholic NaOEt (Claisen, *B.* 20, 656, 2194; Braun, *B.* 22, 556). Monoclinic tables (from chloroform), sl. sol. cold water, v. sol. alkalis. Yields $C_6H_5.CO.CN$ on warming with Ac_2O. Boiling NaOHAq forms NaCy and NaOBz. Its acetyl derivative is converted by NaOHAq into $CHBz(OH).CO.CO.C_6H_5$ [170°] crystallising in minute needles (Söderbaum, *B.* 24, 1386, 3034).

Di-oxim $C_6H_5.C(NOH).CH(NOH)$. *Anti-phenyl-amphi-glyoxim.* [162°] (S.); [168°] (R.). Formed by the action of hydroxylamine on the mono-oxim, or on mono- or di-bromo-acetophenone (Schramm, *B.* 16, 2183; Strassmann, *B.* 22, 419; Russanoff, *B.* 24, 3501). Small needles, v. sol. alcohol, insol. $CHCl_3$; subliming below 160°. N_2O_4 gives $C_6H_5.C_2HN_2O_2$ [c. 90°] crystallising in colourless prisms (Scholl, *B.* 23, 3504). By dissolving in ether and treating with HCl it is converted into an isomeride [180°]. This body, called phenyl-anti-glyoxim, is v. sol. Ac_2O and yields a di-acetyl derivative [92°]. Phenyl-anti-glyoxim is only stable in acid solutions being readily re-converted into the original di-oxim [168°]. By treatment of the di-oxim [168°] NaOHAq and CO_2 at −10° there is formed a second isomeride [148°-154°] called phenyl-syn-glyoxim which yields an oily di-acetyl derivative.—$AgC_8H_7N_2O_2$. Curdy pp.

Phenyl-hydrazide $C_6H_5.C(N_2HPh).CHO$. [148°]. Yellow plates (M. a. P.).

Phenyl-hydrazide $C_6H_5.CO.CH:N_2HPh$. [129°]. Formed by the action of warm dilute KOHAq on the compound got by treatment of sodium benzoylacetic ether with diazobenzene chloride (Stierlin, *B.* 21, 2123). Yellow plates.

p-Tolyl-hydrazide $CHBz:N_2H.C_6H_4Me$. Got in like manner, using *p*-diazotoluene chloride. Yellowish-brown plates, v. sol. ether.

Di-phenyl-di-hydrazide $C_6H_5.C(N_2HPh).CH(N_2HPh)$. [152°]. Got by heating phenyl-glyoxal or, better, the phenyl-hydrazide of benzoyl-carbinol with phenyl-hydrazine hydrochloride and NaOAc at 100° (Laubmann, *A.* 243, 247). Yellow plates.

Di-phenyl-di-methyl-di-hydrazide $C_6H_5.C(N_2MePh).CH(N_2MePh)$. [151°]. Formed from ω-bromo-acetophenone and phenyl-methyl-hydrazine (Culmann, *B.* 21, 2597). Prisms.

Di-phenyl-glyoxal *v.* BENZIL.

PHENYL-GLYOXALINE $C_9H_8N_2$ *i.e.*  $C_6H_5N{<}\begin{array}{l}CH:CH\\CH:N\end{array}$. [13°]. (276°). Formed by warming sulphydro-phenyl-glyoxaline [181°] with dilute HNO_3 or HClAq (Wohl a. Marckwald, *B.* 22, 576, 1353). Crystalline, miscible with alcohol.—$B'HAuCl_4$.—$B'_2H_2PtCl_6$.—Picrate $B'C_6H_3N_3O_7$. [152°]. Yellow needles (from alcohol).—B_2AgNO_3.—B'MeI. Syrup.

Phenyl-glyoxaline  $NH{<}\begin{array}{l}CH:CH\\CPh:N\end{array}$. [148°]. (c. 340°). Formed by distilling its dicarboxylic acid, which is got from di-nitro-tartaric acid, benzoic aldehyde, and NH_3 (Maquenne, *C. R.* 111, 742). Plates (from benzene).—$B'_2H_2C_2O_4$. Needles.—$B'_2H_2PtCl_6$.

Di-phenyl-glyoxaline  $CH{<}\begin{array}{l}NH.CPh\\N-CPh\end{array}$. [227°]. Formed by the action of formic aldehyde and ammonia on benzil (Japp, *C. J.* 51, 559). Dimorphous. Crystallises with di-phenyl-methyl-glyoxaline as $(C_3N_2H_2Ph_2)C_3N_2HMePh_2$ [218°]. —$B'_2H_2PtCl_6$: small flat yellow needles.

Tri-phenyl-glyoxaline *v.* *Lophine*, vol. i. p. 474.

PHENYL-GLYOXIM *v.* *Oxim* of PHENYL-GLYOXAL.

PHENYL-GLYOXYLIC ACID $C_8H_6O_3$ *i.e.* $C_6H_5.CO.CO_2H$. *Benzoyl-formic acid.* [66°].

Formation.—1. From benzoyl cyanide and conc. HClAq in the cold (Claisen, *B.* 10, 429, 844, 1663; 12, 626, 1505) or HOAc saturated with HCl (Buchka, *B.* 20, 395).—2. From di-oxy-ethyl-benzene (phenyl-glycol) and nitric acid of S.G. 1·38 (Zincke, *A.* 216, 305).—3. By saponifying its ether, which is got by heating $COCl.CO_2Et$ with $HgPh_2$ for several hours at 150°; the yield being 40 p.c. of the theoretical (Claisen a. Morley, *B.* 11, 1596).—4. By oxidising acetophenone with alkaline $KMnO_4$ at 0°; the yield being 20 p.c. of the theoretical amount (Glückmann, *M.* 11, 248).

Properties.—Prisms, v. e. sol. water and ether. Decomposed by distillation into benzoic acid and CO, and partly also into benzoic aldehyde and CO_2. Phenyl-hydrazine added to its solution in dilute HCl forms a bulky yellow pp. of phenyl-hydrazide (Ebers, *A.* 227, 340). Whe mixed with benzene (containing thiophene) i gives with conc. H_2SO_4 a red colour changing t violet. On adding water, the layer of benzen becomes crimson.

Reactions.—1. *Sodium-amalgam* reduces i to mandelic acid.—2. HI and P at 160° reduc it to phenyl-acetic acid.—3. *Phenyl mercapta* and gaseous HCl form $C_6H_5.C(SPh)_2.CO_2H$ [142°], sl. sol. benzene (Baumann, *B.* 18, 891). Phenyl mercaptan alone forms a crystallin powder $C_6H_5.C(OH)(SPh).CO_2H$ [69°].

Salts.—NaA'.—KA'aq: dimetric tables.—NH_4A'.—CaA'_2aq: flat prisms.—BaA'_2.—SrA'_2aq—CuA'_2.—$ZnA'_2 2aq$.—PbA'_2.—PbA'_2aq.—AgA'

Methyl ether MeA'. (218°).

Ethyl ether EtA'. (257°). S.G. $^{17.5}$ 1·121. Forms a crystalline compound with $NaHSO_3$. Reacts in alcoholic solution with hydrazine hydrate forming $C_8H_{12}N_4O_2$ [120°] and $C_{20}H_{20}N_2O$ [135°] (Curtius, *J. pr.* [2] 44, 566).

n-Propyl ether PrA'. (174° at 60 mm.).

Isobutyl ether. (174° at 38 mm.).

Isoamyl ether. (182° at 40 mm.).

(α)-*Amide* $C_6H_5.CO.CONH_2$. [91°]. Formed from benzoyl cyanide and cold HClAq. On solution and re-ppn. by CO_2 it forms an unstable hydrate $C_8H_7NO_2aq$ [65°] (so-called (β)-amide).

(γ)-*Amide* $(C_8H_7NO_2)_2$. [134°]. Formed by adding an alcoholic solution of the (α)-amide to dilute HClAq (Claisen). Formed also, together with the (α)-amide, by the action of HOAc saturated with HCl upon BzCy (Buchka). Prisms.

Nitrile *v.* BENZOYL CYANIDE.

(α)-*Oxim* $C_6H_5.C(NOH).CO_2H$. *Isonitroso-phenyl-acetic acid.* [127°]. Formed by the action of hydroxylamine on the Na salt (A. Müller, *B.* 16, 1617) or on the acid at 0° (Hantzsch, *B.* 23, 2333; 24, 42). Thick prisms, v. e. sol. water. Yields α-amido-phenyl-acetic acid on reduction.—KA'aq: very soluble crystals.—$BaA'_2 1\frac{1}{2}aq$.—AgA'.

Acetyl derivative. [119°]. Prisms.

(β)-*Oxim* $C_6H_5.C(NOH).CO_2H$. [145°]. Formed by the action of HCl on an ethereal solution of the (α)-oxim. Formed also by warming phenyl-glyoxylic acid with hydroxylamine and potash. White needles composed of dimetric prisms.

Acetyl derivative. [125°]. Tables.

Methyl ether of the oxim $CPh(NOH).CO_2Me$. [139°]. Got from the Ag salt and MeI (Müller, *B.* 16, 2987). Converted by NaOEt and MeI into $CPh(NOMe).CO_2Me$ [56°], sol. alcohol, insol. alkalis.

Ethyl ether of the oxim $CPh(NOH).CO_2Et$. [113°]. Formed from phenyl-glyoxylic ether and hydroxylamine (Gabriel, *B.* 16, 519). Needles (from hot water).

Nitrile of the oxim $C_6H_5.C(NOH).CN$. [129°]. Formed from phenyl-acetonitrile, amyl nitrite, and alcoholic NaOEt (Frost, *A.* 250, 163; Meyer, *B.* 21, 1306). Formed also by the action of hydroxylamine on dibromo-acetophenone in dilute alcohol at 60° (Russanoff, *B.* 24, 3505). Thin plates, v. sol. alcohol.—$C_6H_5.C(NONa).CN$: yellow powder, v. sol. water. Yields an acetyl derivative [68°].—KA'.—CuA'_2.—$Pb_2A'_2O$.—AgA'.

Phenyl hydrazide $C_6H_5.C(N_2HPh).CO_2H$. [153°]. (F.); [153°-164°] (Von Pechmann, *B.* 25, 1054). Yellow needles, sl. sol. hot water

(Fischer, *B.* 17, 578; Ebers, *A.* 227, 340). May be reduced to $C_6H_5.CH(N_2H_2Ph).CO_2H$ [158°], and finally to aniline and α-amido-phenyl-acetic acid.

Phenyl-methyl-hydrazide $C_6H_5.C(N_2MePh).CO_2H$ [116°]. Plates (from alcohol). Its amide $C_6H_5.C(N_2MePh).CONH_2$ [156°] is crystalline.

Phenyl-ethyl-hydrazide $C_6H_5.C(N_2EtPh).CO_2H$. [109°]. Formed, together with its amide $C_6H_5.C(N_2EtPh).CO.NH_2$ [111°], by the action of phenyl-ethyl-hydrazine in dilute HOAc on phenyl-glyoxylic acid. Yellow plates, sl. sol. water. Yields ethyl-aniline and benzoic aldehyde when heated with conc. HClAq.

References. — AMIDO-, NITRO-, and OXY-PHENYL-GLYOXYLIC ACID.

PHENYL - GLYOXYLIC *o* - CARBOXYLIC ACID $C_6H_4(CO_2H).CO.CO_2H$. [140°]. Formed by oxidising the oxyquinone $C_{16}H_{10}O_3$ or indo-naphthene dihydride carboxylic acid with alkaline $KMnO_4$ (Scherks, *B.* 18, 378; *cf.* Zincke, *A.* 226, 53; 240, 142). Yields CO_2 and phthalic anhydride on heating. May be reduced to phthalide carboxylic acid.—K_2A''. BaA'' 2aq. —$Cu_2A''(OH)_2$ 6aq.—Ag_2A'': crystalline pp.

PHENYL-DIGUANIDE $C_8H_{11}N_5$ *i.e.* $NH:C(NHPh).NH.C(NH_2):NH$. [c. 237°]. Formed by the action of alcoholic ammonia and $AgNO_3$ or $HgCl_2$ on guanyl-phenyl-thio-urea (Bamberger, *B.* 13, 1582). Formed also by heating aniline hydrochloride with di-cyan-di-amide in alcohol at 100° (Smolka a. Friedrich, *M.* 9, 232). Plates, v. sol. water and alcohol; absorbs CO_2 from air. When boiled with baryta-water it yields NH_3, aniline, phenyl-urea [147°], phenyl-guanidine, guanidine, and urea (Emich, *M.* 12, 15).—B'HCl: prisms. Yields phenyl-carbamine when warmed with alcoholic potash and $CHCl_3$.

Salts. — $B'HNO_3$. [209°].— $B'_2H_2SO_4$. — $Cu(C_8H_{10}N_5)_2$ $1\frac{1}{2}$aq: red powder, sol. hot water. — $CuA'_2H_2Cl_2$ $1\frac{1}{2}$aq. — $CuA'_2H_2SO_4$ $1\frac{1}{2}$aq. — $CuA'_2H_2CrO_4$ aq. — NiA'_2. — $NiA'_2H_2Cl_2$. — $NiA'_2H_2SO_4$ $1\frac{1}{2}$aq.—CoA'_2 $1\frac{1}{2}$aq. $CoA'_2H_2Cl_2$ $\frac{1}{2}$aq. —$CoA'_2H_2SO_4$ aq: crimson needles.

(*a*)-**Di-phenyl-diguanide** $C_{14}H_{15}N_5$ *i.e.* $NPh:C(NHPh).NH.C(NH_2):NH$. Formed by the action of $AgNO_3$ and aniline on guanyl-phenyl-thio-urea (Bamberger, *B.* 13, 1581). White solid, m. sol. water and alcohol, alkaline in reaction.—$B'HNO_3$. [231°]. White needles.

(*β*)-**Di-phenyl-diguanide** $NH:C(NPh_2).NH.C(NH_2):NH$. [c. 162°]. Formed by heating diphenylamine hydrochloride with di-cyan-di-amide (Emich, *M.* 12, 21). Thin needles, with alkaline reaction.—$B'HNO_3$. [203°]. Prisms.—$B'_2 3H_2SO_4$.

Tri-phenyl-diguanide $C_{20}H_{19}N_5$. [138°]. Formed from guanyl-tri-phenyl-thio-urea, NH_3, and $AgNO_3$. Formed also from di-phenyl-guanidine and phenyl-cyanamide [78°] in ether (Rathke a. Oppenheim, *B.* 23, 1672). Prisms (from alcohol). With CS_2 at 100° it yields tri-phenyl-thio-ammeline $C_{21}H_{17}N_5S$. — B'HCl: prisms, v. sol. alcohol.—$B'_2H_2PtCl_6$.

PHENYL-GUANIDINE $C_7H_9N_3$ *i.e.* $NH:C(NH_2)(NHPh)$. Formed by desulphuration of phenyl-thio-urea in presence of alcoholic NH_3 (Feuerlein, *B.* 12, 1602). Formed also by the action of baryta-water on phenyl-diguanide (Emich, *M.* 12, 11). Decomposes on standing into phenylcyanamide and ammonia.—*Picrate* $B'C_6H_3N_3O_7$. [208°-214°] (Prelinger, *M.* 13, 99).

Di-phenyl-guanidine $C_{13}H_{13}N_3$ *i.e.* $NH:C(NHPh)_2$. *Melaniline.* [147°]. S. (90 p.c. alcohol) 9·25 at 21°.

Formation.—1. From aniline and CyCl or CyBr (Hofmann, *A.* 67, 129; 74, 8; Weith a. Ebert, *B.* 8, 912).—2. By the action of PbO on a solution of di-phenyl-urea in alcoholic NH_3 (Hofmann, *B.* 2, 452, 688; Weith, *B.* 7, 937; Rathke, *B.* 12, 772).—3. By boiling phenyl-thio-urea with HgCl(NHPh) and alcohol (Forster, *B.* 7, 291; *A.* 175, 35).—4. Together with thio-urea, by the action of aniline on mercuric fulminate (Steiner, *B.* 7, 1244; 8, 518).—5. By combination of di-phenyl-cyanamide with NH_3 (Weith, *B.* 7, 10).

Properties.—Monoclinic prisms (Arzruni, *P.* 152, 281), sl. sol. cold water.

Reactions.—1. Ac_2O at 100° yields acetyl-phenyl-urea [183°]. At 150° the product is acetyl-di-phenyl-urea [115°] (McCreath, *B.* 8, 1181).—2. *Phenyl thiocarbimide* forms, in the cold, NHPh.CS.NPh.C(NH).NHPh [150°], a weak base, sl. sol. benzene.—3. HClAq at 250° forms CO_2, NH_3, and aniline.—4. *Cyanogen* passed into its alcoholic solution forms $C_{15}H_{13}N_5$ which crystallises from alcohol in yellowish needles [154°], decomposed by HClAq into crystalline melanoximide $C_{15}H_{11}N_3O_2$, which is split up by alcoholic potash into oxalic acid and diphenylguanidine, and by alcoholic HCl into NH_3 and di-phenyl-parabanic acid.

Salts.—The hydrochloride is gummy. —$B'HAuCl_4$: golden needles.—$B'_2H_2PtCl_6$.— B'HBr: stellate groups of needles, v. sol. water. — B'HI. — $B'HNO_3$. — B'_2AgNO_3: geodes. — $B'_2H_2SO_4$: stellate groups of plates.—$B'H_2C_2O_4$. —Sulphocyanide: [115°]; m. sol. water.

Di-benzoyl derivative $C_{27}H_{21}N_3O_2$. [102°]. Monoclinic (McCreath, *B.* 8, 383).

Tri-phenyl-guanidine $C_{19}H_{17}N_3$ *i.e.* $NPh:C(NHPh)_2$. Mol. w. 287. [143°]; [147°] (F. a. W.). S. (alcohol) 4·5 at 0°.

Formation.—1. By adding I to an alcoholic solution of di-phenyl-thio-urea alone or mixed with aniline (Hofmann, *B.* 2, 453).—2. From di-phenyl-thio-urea and HgCl(NHPh) (Forster, *B.* 7, 291).—3. From di-phenyl-cyanamide $C(NPh)_2$ and aniline (Weith, *B.* 7, 10).—4. Together with phenyl-thiocarbimide by heating di-phenyl-cyanamide with di-phenyl-urea (Weith, *B.* 9, 810).—5. By boiling di-phenyl-urea with inverted condenser (Barr, *B.* 19, 1765).—6. By heating di-phenyl-thio-urea with aniline, with Cu, or with $PbCl_2$ (Merz a. Weith, *Z.* [2] 4, 513, 609; 5, 583, 659; Girard, *Bl.* [2] 46, 506), or with $HgCl_2$ at 145° (Buff, *B.* 2, 498).—7. By heating di-phenyl-cyanamide (2 mols.) with phenylene-*o*-diamine (1 mol.) at 210° (Keller, *B.* 24, 2505). 8. By the action of aniline on CCl_4 or chloropicrin (Hofmann; Basset, *C. J.* 18, 31).—9. By the action of PCl_3 (1 mol.) on a mixture of di-phenyl-urea (3 mols.) and aniline (3 mols.).—10. By the action of PCl_3 (2 mols.) and CO_2 (3 mols.) on aniline (9 mols.) at 170° (Merz a. Weith, *Z.* [2] 6, 160).—11. By fusing di-phenyl-urea with NaOH (Hentschel, *J. pr.* [2] 27, 500). 12. From phenyl thiocarbimide by chlorinating and heating the product $NPh:CCl_2$ with aniline (Sell a. Zierold, *B.* 7, 1231). The base got is possibly an isomeric tri-phenyl-guanidine.—13. A product of the action of $CSCl_2$ on $CS(NHPh)_2$ and benzene (Freund a. Wolf, *B.* 25, 1464).

Properties.—Trimetric six-sided prisms (from alcohol); *a*:*b*:*c* = ·670:1:·558, nearly insol. boiling water. Occurs also in an amorphous form (Giraud, *Bl.* [2] 46, 505). Decomposed above 250° into aniline and $C(NPh)_2$. $KClO_3$ (1½ pt.) and HCl give a greenish solution, depositing dark flakes which dissolve in alcohol with violet colour.

Reactions.—1. CS_2 at 170° forms $CS(NPhH)_2$ and phenyl thiocarbimide.—2. H_2S passed through it at 170° forms aniline and di-phenyl-urea (Merz a. Weith, *Z.* [2] 6, 72).—3. *Water* at 175° forms aniline and di-phenyl-urea.—4. Conc. KOHAq or conc. HClAq yield aniline and CO_2 on heating.—5. *Cyanogen* passed into the alcoholic solution forms crystals of $C_{21}H_{17}N_5$ which is decomposed by HClAq into NH_4 and the **oxalyl-derivative** $C(NPh)<\begin{matrix}NPh.CO\\NPh.CO\end{matrix}$ [c. 230°] which is itself decomposed by boiling with alcohol and HClAq into aniline and di-phenyl-parabanic acid (Hofmann, *B.* 3, 761; Stojentin, *J. pr.* [2] 32, 1).—6. *Chloro-glyoxylic ether* $COCl.CO_2Et$ forms a **carbonyl derivative** $C(NPh)<\begin{matrix}NPh\\NPh\end{matrix}>CO$ which forms the salts B′HCl [190°] and $B'HNO_3$ [185°] (Stojentin).—7. $COCl_2$ forms the above (?) carbonyl derivative $C_{20}H_{15}N_3O$, which crystallises from CS_2 in tables [134°] and forms a hydrate B′aq [141°] (Michler a. Keller, *B.* 14, 2181).

Salts.—B′HCl aq. [242°] (Weith, *B.* 9, 810); [245°] (F. a. W.). S. 2 at 0°.—$B'HNO_3$: laminæ.—$B'_2H_2PtCl_6$. S. ·09 at 0°.—$B'H_2SO_4$: broad needles.—B′HOAc.—$B'H_2C_2O_4$: laminæ.—$B'C_6H_3N_3O_7$. [178°]. S. ·0082 at 15° (Prelinger, *M.* 13, 98).

Acetyl derivative $C(NPh)(NPhAc)_2$. [131°]. Crystals (MacCreath, *B.* 8, 383).

Benzoyl derivative $C(NPh)(NPhBz)_2$. [185°]. Plates (from alcohol).

(β)-Tri-phenyl-guanidine $C(NH)(NHPh)(NPh_2)$. [131°]. Formed by heating phenyl-cyanamide (cyanilide) CN.NHPh with diphenylamine at 125° (Weith a. Schröder, *B.* 8, 912). Regular tablets, nearly insol. water. Its solution in conc. H_2SO_4 becomes violet on heating.

Reactions.—1. Conc. HClAq or KOHAq at 260° forms CO_2, NH_3, aniline, and $NHPh_2$.—2. CS_2 at 160° forms the sulphocyanide, H_2S, phenyl-thiocarbimide and $NHPh_2$.

Salts.—B′HCl aq. S. (of B′HCl) 28·4 at 23°.—$B'_2H_2PtCl_6$: crystalline.

Dicyanide $C_{21}H_{17}N_5$. [173°]. A product of the action of cyanogen as an alcoholic solution of aniline (Hofmann, *A.* 66, 129; *B.* 3, 763). Got also by boiling the compounds of cyanogen with di-phenyl-guanidine or (α)-tri-phenyl-guanidine with aniline hydrochloride (Landgrebe, *B.* 10, 1593; 11, 973). Dark-brown needles (containing ½aq) with violet iridescence (from alcohol).—B′HCl 3aq: brown needles.

Tetra-phenyl-guanidine $C(NH)(NPh_2)_2$. [131°]. Formed by passing gaseous cyanogen chloride through diphenylamine at 160° (Weith, *B.* 7, 843). Pyramids (from ligroïn), insol. water, v. sol. alcohol and ether. Conc. H_2SO_4 forms a colourless solution turned violet-red by heat. CS_2 at 260° forms tetra-phenyl-thio-urea. Solid KOH at 200°, and conc. HClAq at 340°, yield NH_3, CO_2, and $NHPh_2$.

Salts.—B′HCl 5aq. Efflorescent tablets.—$B'_2H_2PtCl_6$.—$B'HNO_3$.

References.—DI-BROMO-, DI-CHLORO-, DI-IODO-, and NITRO- PHENYL-GUANIDINES.

DI-PHENYL-GUANIDINE CARBOXYLIC ACID $C(NH)(NHPh).NH.C_6H_4.CO_2H$. *Phenyl-guanido-benzoic acid.* [165°]. Formed by heating *m*-cyanamido-benzoic acid or cyancarbimido-amido-benzoic acid with aniline (Traube, *B.* 15, 2120; Griess, *B.* 16, 336). Crystals (containing aq), nearly insol. alcohol and ether, sol. hot water, aqueous alkalis and acids.—HA′HCl aq.

Reference.—AMIDO-DI-PHENYL-GUANIDINE CARBOXYLIC ACID.

PHENYL-GUANIDO-ACETIC ACID $C_9H_{11}N_3O_2$ *i.e.* $C(NH)(NHPh).NH.CH_2.CO_2H$. [260° uncor.] Formed from phenyl-cyanamide and glycocoll (Berger, *B.* 13, 992). Crystals.

DI-PHENYL-DI-GUANIDO-DI-TOLYL-SULPHIDE $S(C_7H_6.NH.C(NH).NHPh)_2$. *Thio-p-tolyl-di-phenyl-di-guanidine.* [153°]. Formed by heating di-phenyl-di-uramido-di-tolyl sulphide with alcoholic NH_3 and HgO (Truhlar, *B.* 20, 675). Small white needles (from ether-ligroïn). V. sol. alcohol, benzene, and ether.—$B''H_2Cl_2PtCl_4$: yellow amorphous powder.

Tetra-phenyl-di-guanido-di tolyl-sulphide $S(C_7H_6.NH.C(NPh).NHPh)_2$. *Thio-p-tolyl-tetra-phenyl-di-guanidine.* [106°]. Formed by heating di-phenyl-di-uramido-di-tolyl sulphide with aniline and HgO (T.). Amorphous powder.

PHENYL-HEPTADECYL-THIO-UREA $C_6H_5NH.CS.NHC_{17}H_{35}$. [79°]. Formed by boiling heptadecyl-thiocarbimide with aniline and alcohol (Turpin, *B.* 21, 2491).

PHENYL-HEPTADECYL-UREA $C_{24}H_{42}N_2O$ *i.e.* $C_6H_5NH.CO.NHC_{17}H_{35}$. [99°]. Formed by heating heptadecylamine hydrochloride with $COCl_2$ in benzene at 100°, the product being heated with aniline (Turpin, *B.* 21, 2492).

PHENYL-HEPTANE *v.* HEPTYL-BENZENE.

Di-phenyl-heptane $C_6H_{13}.CHPh_2$. [14°]. (191° at 13 mm.). Formed from $C_6H_{13}.CHCl_2$, benzene, and $AlCl_3$ (Anger, *Bl.* [2] 47, 48; Krafft, *B.* 19, 2986). Needles.

PHENYL-HEPTENOIC ACID $C_{13}H_{16}O_2$ *i.e.* $Ph.CEt:CEt.CO_2H$ (?) Oil. Got by passing CO over a heated mixture of NaOEt and sodic cinnamate (M. Schroeder, *A.* 221, 52).

PHENYL HEPTYL KETONE CARBOXYLIC ACID $C_6H_5.CO.CH_2.CH(C_5H_{11}).CO_2H$. [103°]. Formed by heating phenacyl-isoamyl-malonic acid (Paal a. Hofmann, *B.* 23, 1504). Plates, insol. water, sl. sol. ligroïn. On repeated distillation it yields an oily lactone (310°–320°).

Ethyl ether EtA′. (260°). Oil.

PHENYL-HEXINENE *v.* BUTENYL-STYRENE.

DI-PHENYL-HEXOIC ACID. *Nitrile.* $CH_2Ph.CPhPr.CN$. [63°]. (330°–340°). Formed from $C_6H_5.CHPr.CN$, benzyl chloride, and NaOH (Rossolymo, *B.* 22, 1236). Needles.

TETRA-PHENYL-HEXUNENE $\begin{matrix}CPh\\CPh\end{matrix}>CH.CH<\begin{matrix}CPh\\CPh\end{matrix}$. [260°]. Formed by heating di-benzyl-carbinol with MeI at 265° (Bogdanowska, *B.* 25, 1273). Needles, insol. alcohol and ether, sol. $CHCl_3$.

PHENYL-HEXYL-TRIAZOLE CARBOXYLIC ACID  $CH_3(CH_2)_5C\left\langle\begin{matrix}N.NPh\\N:C.CO_2H\end{matrix}\right.$ [126°]. Obtained by saponifying its nitrile, which is got from phenyl-hydrazine dicyanide and heptoic aldehyde (œnanthol) (Bladin, *B.* 25, 186). Silvery plates, v. sol. alcohol.—CuA'_2 aq.—HA'HCl.

Amide. [82·5°]. White plates.

Thio-amide $C_{11}H_{18}N_2.CS.NH_2$. [77°]. Formed from the crude nitrile and alcoholic ammonium sulphide. Yellow plates, sol. alcohol.

DI-PHENYL-HEXYL-TRICYANIDE  $N\left\langle\begin{matrix}CPh.N\\CPh:N\end{matrix}\right\rangle C.(CH_2)_5.CH_3$. [44°]. (265° at 15 mm.). Got from heptoyl chloride, benzonitrile, and $AlCl_3$ at 70° (Krafft a. Hanssen, *B.* 22, 808).

PHENYL HEXYL KETONE $C_6H_5.CO.C_6H_{13}$. [17°]. (267°) at 740 mm. Formed by the action of $AlCl_3$ on a mixture of benzene and heptoyl chloride (Auger, *Bl.* [2] 47, 50; Krafft, *B.* 19, 2987). Leaflets. Yields an oxim [55°].

PHENYL-HEXYL-(β)-NAPHTHOTRIAZINE. *Dihydride* $C_{23}H_{25}N_3$ *i.e.*  $C_{10}H_6\left\langle\begin{matrix}N.CH.C_6H_{13}\\N.NPh\end{matrix}\right.$. [176·5°]. Formed by heating benzene-azo-(β)-naphthylamine with œnanthol and alcohol (Goldschmidt a. Poltzer, *B.* 24, 1007). Needles, sol. alcohol.—B'HCl. [226°]. White needles.—$B'_2H_2PtCl_6$. [225°]. Granules.

PHENYL-HEXYL-PYRAZOLE $C_{15}H_{20}N_2$ *i.e.*  $C_6H_{13}.C\left\langle\begin{matrix}CH-CH\\NPh.N\end{matrix}\right.$. (319°). Formed from heptoyl-acetic aldehyde and phenyl-hydrazine (Claisen a. Stylos, *B.* 21, 1149). Oil.

PHENYL-HEXYL-THIO-UREA $C_{13}H_{20}N_2S$ *i.e.* $CS(NHPh).NH.CH_2.CHEt_2$. [53°]. Formed from hexylamine and phenyl-thiocarbimide (Freund a. Herrmann, *B.* 23, 195). Prisms.

PHENYL-HEXYL-UREA $C_{13}H_{20}N_2O$ *i.e.* $CO(NHPh).NH.CH_2.CHEt_2$. [70°]. Formed from hexylamine and phenyl cyanate (Freund a. Herrmann, *B.* 23, 194). Needles.

PHENYL-HOMO-ITAMALIC ACID *v.* OXY-BENZYL PYROTARTARIC ACID.

PHENYL-HYDANTOÏC ACID $NH_2.CO.NH.CHPh.CO_2H$. [178°]. Got by boiling (α)-phenyl-hydantoïn with baryta (Pinner, *B.* 21, 2326). Prisms, sl. sol. cold water.

Amide $NH_2.CO.NH.CHPh.CO.NH_2$. [223°]. Formed by adding the compound got from urea and the cyanhydrin of benzoic aldehyde to H_2SO_4 and pouring into water at 0° (Pinner a. Spilker, *B.* 22, 697). Prisms (from dilute alcohol). Yields phenyl-hydantoïn on heating.

PHENYL-HYDANTOÏN $C_9H_8N_2O_2$ *i.e.*  $CO\left\langle\begin{matrix}NH\ .CO\\NPh.CH_2\end{matrix}\right.$. [192°]. Formed by fusing urea with phenyl-amido-acetic acid (Schwebel, *B.* 10, 2045). Needles, v. sl. sol. water, sol. alkalis.

(α)-Phenyl-hydantoïn  $CO\left\langle\begin{matrix}NH.CO\\NH.CHPh\end{matrix}\right.$. *Di-oxy-phenyl-glyoxaline.* [178°]. Formed by heating the cyanhydrin of benzoic aldehyde with mandelic nitrile at 100° (Pinner, *B.* 21, 2321). Formed also from phenyl-uramido-acetic ether and KOH (Kossel, *B.* 24, 4150). Needles (from HClAq). KOH and MeI yield $C_9H_7MeN_2O_2$ [162°], crystallising in needles.—KA': needles, v. sol. water.

Acetyl derivative $C_9H_7AcN_2O_2$. [145°]. Small needles (from benzene), insol. water.

Phenyl-ψ-hydantoïn  $C(NH)\left\langle\begin{matrix}NH.CO\\O\quad CHPh\end{matrix}\right.$. [above 300°]. Got by dissolving (α)-phenyl-hydantoïn in alcoholic potash and then adding HCl. Crystalline.—KA': almost insol. water.

Acetyl derivative  $C(NH)\left\langle\begin{matrix}NAc.CO\\O\quad CHPh\end{matrix}\right.$. White prisms (Pinner a. Spilker, *B.* 22, 698). Decomposes at about 290°.

PHENYL-HYDRAZIDO-ACETIC ACID $C_6H_5NH.NH.CH_2.CO_2H$. [159°]. Formed by reducing the phenyl-hydrazide of glyoxylic acid (Elbers, *A.* 227, 353). Formed also by reducing phenyl-osotriazole carboxylic acid with sodium-amalgam (Pechmann, *A.* 262, 288). Hexagonal tables, sol. hot water. Re-oxidised by Fehling's solution to $NHPh.N:CH.CO_2H$.

u-**Phenyl-hydrazido-acetic acid** $NH_2.NPh.CH_2.CO_2H$. [131°]. Got by saponifying its ether [127°], which is formed by heating phenyl-hydrazine with chloro-acetic ether at 100° (Reissert a. Kayser, *B.* 24, 1519). Needles.

PHENYL-HYDRAZIDO-BUTYRIC ACID $C_{10}H_{14}N_2O_2$ *i.e.* $CHEt(N_2H_2Ph).CO_2H$. Formed by reducing the phenyl-hydrazide of ethyl-glyoxylic acid (Japp a. Klingemann, *A.* 247, 217). Needles (from MeOH). Softens at 165°.

Phenyl-hydrazido-isobutyric acid $CMe_2(N_2H_2Ph).CO_2H$.

Anhydride  $N_2HPh\left\langle\begin{matrix}CMe_2\\CO\end{matrix}\right.$. [175°]. Got by gently heating the nitrile with H_2SO_4 and pouring into water (Reissert, *B.* 17, 1458). Crystals, v. sol. alcohol.—B'HCl: crystals.

Nitrile $CMe_2(N_2H_2Ph).CN$. [70°]. Got by heating the cyanhydrin of acetone with phenyl-hydrazine at 100°. Needles, v. sol. alcohol.

Imide $(CMe_2(N_2H_2Ph).CO)_2NH$. [117°]. Got by passing HCl into an alcoholic solution of the nitrile.—$B'''H_3Cl_3$: crystals.

Phenyl-hydrazido-butyric acid $NH_2.NPh.CHMe.CH_2.CO_2H$. [111°]. Formed from potassium β-bromo-butyrate, phenyl-hydrazine and NaOAc in aqueous solution (Lederer, *J. pr.* [2] 45, 87). Plates (from alcohol), v. sol. hot Aq. Converted by conc. H_2SO_4 into oxy-phenyl-methyl-pyrazole dihydride.

PHENYL - β - HYDRAZIDO - CROTONIC ETHER $CH_3.C(NH.NHPh):CH.CO_2Et$. [50°]. Formed from acetoacetic ether (1 mol.) dissolved in ether by adding phenyl-hydrazine (Nef, *A.* 266, 70; *cf.* Knorr, *A.* 238, 147). Colourless needles, v. e. sol. ether, sl. sol. ligroïn. Turns yellow in air. Split up by conc. HClAq into phenyl-hydrazine and acetoacetic ether. When heated *in vacuo* at 200° it changes to oxy-phenyl-methyl-pyrazole. Conc. H_2SO_4 followed, after 10 minutes, by water forms methyl-indole carboxylic ether [134°]. HgO oxidises it to the azo-compound $CH_3.C(N_2Ph):CH.CO_2Et$ crystallising from light petroleum in red needles [51°]. AcCl forms a di-acetyl derivative $CH_3.C(NAc.NAcPh):CH.CO_2Et$ (245°–250° at 150 mm.).

PHENYL-HYDRAZIDO-METHYL-QUINOLINE $C_9H_5MeN(N_2H_2Ph)$. [197°]. Formed from

(*Py.* 3) methyl-quinoline and phenyl-hydrazine (Ephraim, *B.* 24, 2820).

PHENYL - HYDRAZIDO - METHYL - THIAZOLE. *Dihydride* $C_{10}H_{13}N_3S$ *i.e.*

$$\begin{matrix}CHMe.S\\CH_2—N\end{matrix}\!\!>C.NH.NHPh.$$

Phenyl-propylene-ψ-thio-semicarbazide. [93°]. Formed by heating phenyl-allyl-thio-urea with conc. HClAq at 100° (Arenarius, *B.* 24, 269). Yellowish plates (from ligroïn).—B'HCl. [202°]. Concentric crystals. —*Picrate.* [167°].

PHENYL - HYDRAZIDO - PHENYL - ACETIC ACID $C_{14}H_{14}N_2O_2$ *i.e.* NHPh.NH.CHPh.CO_2H. [158°]. Got by reducing the phenyl-hydrazide of phenyl-glyoxylic acid (Elbers, *A.* 227, 315). Crystalline, v. sl. sol. cold water, v. sol. alcohol.

PHENYL-HYDRAZIDO-PROPIONIC ACID $C_9H_{12}N_2O_2$ *i.e.* NH_2.NPh.CHMe.CO_2H. [187°]. Formed by boiling its amide with NaOHAq (Reissert, *B.* 17, 1454; 20, 3110; 22, 2924). The ether is got by heating lactic ether with phenyl-hydrazine. Needles. Yields phenyl-α-amido-propionic acid on reduction.

Ethyl ether EtA'. [116°].—EtA'HCl.

Nitrile. [58°]. Formed by heating CH_3.CH(OH).CN with phenyl-hydrazine at 100°.

Amide. [124°]. White crystals.

Phenyl-hydrazido-propionic acid NHPh.NH.CHMe.CO_2H. [172°]. Formed by reducing the phenyl-hydrazide of pyruvic acid with sodium-amalgam (Fischer a. Jourdan, *B.* 16, 2244; Japp a. Klingemann, *B.* 20, 3284; *A.* 247, 211). Needles (from MeOH). Re-oxidised by cold Fehling's solution to NHPh.N:CMe.CO_2H.

PHENYL-HYDRAZIDO-QUINOLINE C_9H_6N.NH.NHPh. [191°]. Formed from (*Py.* 3)-chloro-quinoline and phenyl-hydrazine (Ephraim, *B.* 24, 2818). Needles, v. sol. chloroform. Reduced by HI and P to (*Py.* 3)-amido-quinoline.

PHENYL-HYDRAZINE $C_6H_8N_2$ *i.e.* NHPh.NH_2. [23°]. (241·5° i.V.) at 750 mm. S.G. $\frac{22.7}{4}$ 1·097 (E. Fischer, *A.* 236, 198). H.C.v. 805,240. H.C.p. 806,300. H.F. 34,200 (from diamond) (Petit, *A. Ch.* [6] 17, 168).

Formation.—(E. Fischer, *B.* 8, 589, 1005, 1641; 9, 111, 880; *A.* 190, 67).—By the action of zinc and HOAc on diazo-benzene anilide or diazo-benzene diethylamide.

Preparation.—1. A cold solution of $7\frac{1}{2}$ pts. of sodium nitrite in 50 pts. of water is slowly added to a well-cooled mixture of 10 pts. of aniline and 200 pts. of HCl (30 p.c.). To the diazo-benzene chloride solution so prepared a cold solution of 45 pts. of stannous chloride in 45 pts. of HCl is now added, when the mixture immediately becomes a thick magma of phenyl-hydrazine hydrochloride, which is filtered off, basified, and distilled (Meyer a. Lecco, *B.* 16, 2976).—2. Aniline (28 g.) is dissolved in K_2CO_3 (21 g.) and water (500 c.c.) by passing in SO_2. The solution is mixed with a cold solution of $NaNO_2$ (25 g.) exactly neutralised by HOAc. After two hours the product is warmed till dissolved, acidified by HOAc, and reduced with zinc-dust and HClAq (Reychler, *B.* 20, 2463). By adding diazo-benzene nitrate to a cold aqueous solution of $KHSO_3$, heating the resulting $C_6H_5.N_2.SO_3K$ with excess of $KHSO_3$, and decomposing the C_6H_5.NH.NH.SO_3K, thus formed, by heating with HClAq.

Properties.—Oil, solidifying to monoclinic tables; v. sl. sol. hot water, almost insol. KOHAq. Miscible with alcohol, ether, benzene, and $CHCl_3$. Volatile with steam. Reduces Fehling's solution in the cold, N, aniline, and benzene being formed. When heated for a long time at 150° it is gradually split up into aniline, NH_3, benzene, and N (Reissert a. Kayser, *B.* 23, 3703). Reduces SeO_2 to Se (Hinsberg, *A.* 260, 42). Gives benzene and N when boiled with $CuSO_4$. It is very poisonous.

Reactions.—1. H_2O_2 forms benzene and diazo-benzene imide PhN_3 (Wurster, *B.* 20, 2633).—2. Yellow HgO added to its ethereal solution forms aniline, N, and $HgPh_2$ (Fischer, *A.* 199, 320). HgO added to a solution of the sulphate forms diazo-benzene sulphate and imide.—3. $SOCl_2$ in ether forms in the cold NPhH.N:SO, which crystallises in yellow prisms [105°]; v. sol. ether, volatile with steam. Thionyl-phenyl-hydrazine is hardly attacked by HCl, but is converted by NaOHAq into phenyl-hydrazine and Na_2SO_3. Br forms NPhBr.NBr_2. AcCl forms diazo-benzene chloride, S, and HOAc (Michaelis, *B.* 22, 2228; *A.* 270, 115).—4. SO_2 passed into an ethereal solution of phenyl-hydrazine forms NHPh.$NH_2.SO_2$ as a crystalline pp. SO_2 passed into an alcoholic solution of phenyl hydrazine forms $(NHPh.NH_2)_2SO_2$; v. sol. water and alcohol, insol. ether, crystallising in tables which shrink together at 70°, but decompose at a higher temperature (Michaelis a. Ruhl, *B.* 23, 474). SO_2 passed into a benzene solution at 75° forms NHPh.N:SO, which when heated with phenyl-hydrazine gives Ph_2S_2, benzene, and N.—5. Dry CO_2 forms solid phenyl-hydrazine phenyl-carbazate $(NHPh.NH_2)_2CO_2$ or $N_2PhH_2.CO.O.N_2PhH_4$, which is crystalline; sl. sol. water and ether, decomposed by hot water.—6. CS_2 forms the corresponding $N_2PhH_2.CS.S.N_2PhH_4$ [97°], which at 110° splits up into H_2S and di-phenyl-thiocarbazide. COS forms crystalline $COS(N_2H_3Ph)_2$ (Fischer, *B.* 22, 1935).—7. *Zinc-dust* and conc. HClAq slowly form aniline and NH_3.—8. Excess of phenyl-hydrazine acts upon *iodine*, forming HI, aniline, and PhN_3 (Fischer, *B.* 10, 1335). Excess of I forms iodo-benzene, N, and HI (E. von Meyer, *J. pr.* [2] 36, 115). This reaction may be used for the volumetric estimation of phenyl-hydrazine.—9. *Sulphur* above 80° forms aniline, H_2S, N, Ph_2S_2, Ph_2S, PhSH, benzene, and NH_3.—10. *Nitrous acid* forms PhN_3. KNO_2 added to the hydrochloride at 0° forms a yellow crystalline pp. of NPh(NO)NH_2.—11. *Alcoholic potash* and *chloroform* form, on heating, $C_{14}H_{12}N_4$ [180°], mol. w. 236. This body crystallises in white needles; sol. alcohol, scarcely affected by HClAq at 200°, and yielding crystalline $C_{14}H_{11}N_4.NO_2$ and $C_{14}H_{11}N_4.SO_3H$ (Ruhemann a. Elliott, *C. J.* 53, 850).—12. EtBr forms NPhEt.NH_2, NPhH.NHEt, and $NPhEt_2Br.NH_2$.—13. Aqueous *diazobenzene nitrate* added to a cold solution of the hydrochloride ppts. PhN_3, aniline nitrate remaining in solution.—14. Reacts with aldehydes and ketones, forming phenyl-hydrazides; *e.g.* (Fischer, *B.* 17, 572) $CH_3.CHO + NPhH.NH_2 = H_2O + CH_3.CH:N.NHPh$. Thus a solution of phenyl-hydrazine hydrochloride (2 pts.) and crystallised sodium acetate (3 pts.) in water (20 pts.) gives a pp. of the phenyl-hydrazide when added to an aqueous solution of an aldehyde or ketone, either in the cold, or, in the case of aromatic compounds, on warming. These phenyl-hydrazides are decomposed by acids into the original components, and, in alcoholic solution, by sodium-amalgam and HOAc into aniline and a base. The phenyl-hydrazides of ketones are converted by $ZnCl_2$ into derivatives of indole. The phenyl-hydrazides of aldehydes and ketones are described under the aldehydes and ketones from which they are derived.—15. *Diketones* containing the group CO.CHX.CO yield derivatives of phenyl-pyrazole. Saturated γ-diketones in ethereal solution usually form a mono- or di- phenyl-hydrazide; in HOAc the product is the anhydride of the mono-phenyl-hydrazide, a derivative either of  $\begin{matrix}CH_2.CH:N\\CH:CH.NPh\end{matrix}$ or of  $\begin{matrix}CH:CH\\CH:CH\end{matrix}\!\!>N.NHPh$ (Klingemann, *A.* 269, 108).—16. *Acetoacetic ether* forms a phenyl-hydrazide, which at 140° changes to oxy-phenyl-methyl-pyrazole  $NPh<\begin{matrix}CO.CH_2\\N\ :CMe\end{matrix}$ by loss of alcohol. *Acetyl-propionic acid* forms the compound $CH_3.C(N_2HPh).CH_2.CH_2.CO_2H$ [108°]. *Benzoylacetic ether* forms two compounds [132°] and [165°] (Bender, *B.* 21, 2495).—**17.** Reacts with *sugars* as with aldehydes; thus a solution of glucose gives $CH_2(OH).(CH(OH))_4.CH:N_2HPh$ [145°] on heating with phenyl-hydrazine, while galactose gives $C_6H_{12}O_5(N_2HPh)$ [158°] (Fischer, *B.* 20, 824). On heating these compounds with aqueous phenyl-hydrazine acetate at 100° 'osazones' are formed, *e.g.* phenyl-glucosazone $CH_2OH.(CH.OH)_3.C(N_2HPh).CH:N_2HPh$ [204°] and the isomeric phenyl-galactosazone [c. 191°]. 18. By heating with phenyl-hydrazine hydrochloride and NaOAc *arabinose* is converted into $C_{17}H_{20}N_4O_3$ [158°]; *formose* into $C_{18}H_{22}N_4O_4$ [c. 144°]; *acrose* (the product of the action of NaOHAq on glyceric aldehyde) into $C_{18}H_{22}N_4O_4$ [c. 217°] and an isomeride [159°].—19. Phenyl hydrazine acetate reacts with the *product of oxidation of glycerin* with Na_2CO_3Aq and Br forming glycerosazone $C_{15}H_{16}N_4O$ crystallising from benzene in yellow plates [131°] (Fischer a. Tafel, *B.* 20, 1089, 3386).—20. *Erythrite*, after oxidation by dilute HNO_3, yields with phenyl-hydrazine hydrochloride and NaOAc the compound $C_4H_6O_2(N_2HPh)_2$ [167°]. 21. *Mannite* on oxidation with HNO_3 yields levulose (mannitose) and mannose, which with phenyl-hydrazine forms $C_{12}H_{18}N_2O_5$ [195°-200°] (Fischer, *B.* 21, 1805).—22. The acetate reacts with the *product of oxidation of dulcite* by bromine and Na_2CO_3Aq with formation of the 'phenyldulciteosazone' $C_{18}H_{22}N_4O_4$ [206°].—23. *Isodulcite* heated with phenyl-hydrazine hydrochloride and sodium acetate at 100° forms 'phenyl-isodulcite-osazone' $C_{18}H_{22}N_4O_3$ or $C_6H_{10}O_3(N_2HPh)_2$ [180°]. Solutions of *isodulcite* and phenyl-hydrazine form, on mixing, $C_6H_{12}O_4(N_2HPh)$ [159°] (Fischer a. Tafel, *B.* 20, 2574; Raymann, *Bl.* [2] 47, 760).—24. *Sorbin* heated with aqueous phenyl-hydrazine hydrochloride and NaOAc at 100° forms the osazone $C_{18}H_{22}N_4O_4$ [164°].—25. *Milk sugar* heated with aqueous phenyl-hydrazine hydrochloride and NaOAc forms $C_{24}H_{32}N_4O_9$ [200°] and $C_{24}H_{30}N_4O_8$ [224°].—26. *Maltose* forms $C_{21}H_{32}N_4O_9$ [191°].—27. The acetate gives with *glyoxylic, phenyl-glyoxylic*, and *pyruvic acids* the corresponding phenyl-hydrazides [137°], [153°], and [192°] respectively.—28. Phenyl-hydrazine in HOAc (50 p.c.) gives with a dilute solution of *gluconic, galactonic, and arabinose carboxylic acids* compounds $C_6H_{11}O_6.N_2H_2Ph$ [200°], [203°], and [216°] respectively (Fischer a. Passmore, *B.* 22, 2760). These compounds are m. sol. hot water. *Saccharic acid* gives a similar compound $C_6H_{11}O_5N_2H_2Ph$ [165°] which, as well as the compounds from mucic and meta-saccharic acid, is almost insoluble. The compound from mucic acid melts at 240°. All these compounds contain the group CO.NH.NHPh. Compounds containing this group are also obtained by the action of phenyl-hydrazine and dilute HOAc at 100° on *formic, succinic, malic, tartaric, cinnamic*, and *gallic acids*, but not from *glycollic, lactic*, and *glyceric acids*. The compounds got from succinic, malic, gallic, and tartaric acid melt at 218°, 223°, 187°, and 240° respectively. Acetyl-phenyl-hydrazine is produced when aqueous phenyl-hydrazine acetate is heated at 130°; and a similar reaction occurs with benzoic, glyceric, and lactic acids. Compounds containing the group CO.NH.NHPh give a reddish-violet colouration with H_2SO_4 and a little $FeCl_3$, and they are readily decomposed by KOHAq and by baryta into phenyl-hydrazine and a salt of the acid (Fischer, *B.* 22, 2728).—29. *Glucose carboxylic lactone* yields $C_7H_{13}O_7.N_2H_2Ph$ [172°], while *mannose carboxylic acid* gives an isomeric body [223°].—30. The acetate gives with *rhamnose carboxylic acid* the compound $C_7H_{13}O_7N_2H_2Ph$ [c. 210°], while 31. *Malonic acid* heated at 100° with phenyl-hydrazine and dilute HOAc forms $C_{15}H_{18}N_4O_2$ [143°] and $CO_2H.CH_2.CO.N_2H_2Ph$ [154°], which when heated with water and phenyl-hydrazine at 200° yields  $CH_2<\begin{matrix}CO\\CO\end{matrix}\!\!>N_2HPh$ [128°].—32. *Lactic ether* forms, on heating, phenyl-hydrazido-propionic ether. *a-Oxy-butyric acid* at 160° forms $C_{10}H_{11}N_2O_2$ [152°], while mandelic acid yields $C_{14}H_{11}N_2O_2$ [182°] (Reissert a. Kayser, *B.* 22, 2924).—33. *γ-Oxy-valeric lactone* at 100° forms $C_5H_8O_2N_2PhH_3$ [79°] (Wislicenus, *B.* 20, 402).—34. *Benzoyl-carbinol* gives $N_2HPh:CPh.CH_2OH$ [112°] and the 'osazone' $N_2HPh:CPh.CH:N_2HPh$ [192°] (Laubmann, *A.* 243, 244).—35. Boiling aqueous *itaconic acid* forms the acid  $NHPh.N<\begin{matrix}CH_2.CH.CO_2H\\CO\ .\ CH_2\end{matrix}$ [194°] (Scharfenberger, *A.* 254, 150).—36. *Cinnamic acid* forms $C_{13}H_{14}N_2O$ [183°], which on distillation yields $C_{15}H_{12}N_2O$ [251°] (Knorr, *B.* 20, 1107).—37. *Acrolein* reacts forming phenyl-pyrazole dihydride  $NPh<\begin{matrix}N:CH\\CH_2.CH_2\end{matrix}$ [52°] (274°) (Fischer a. Knoevenagel, *A.* 239, 194).—38. *Mesityl oxide* yields phenyl-tri-methyl-pyrazole  $NPh<\begin{matrix}N=CMe\\CMe_2.CH_2\end{matrix}$ (F. a. K.).—39. *Chloro-acetone* in alcoholic solution at −18° forms $C_{24}H_{26}N_6$ [158°] which yields an acetyl derivative $C_{24}H_{25}AcN_6$ [220°] (Bender, *B.* 21, 2496). *s-Tetra-chloro-acetone* forms $C_{15}H_{12}N_4$ [126°] converted by fuming HNO_3 into $C_{15}H_{10}N_6O_5$ [235°] and by $SnCl_2$ to two bases $C_{15}H_{11}N_4$ [77°] and [193°] (Levy a. Witte, *A.* 252, 343; Zincke a. Kegel, *B.* 22, 1478).—40. *Tetra-bromo-di-benzyl-ketone* heated with alcoholic phenyl-hydrazine at 150° forms $C_3Ph_2(N_2Ph)_2$ [70°] (Bourcart, *B.* 22, 1369).—41. *Di-bromo-aceto* *phenone* forms $N_2HPh:CPh.CH:N_2HPh$ [148°], crystallising from alcohol in yellow prisms (B.). 42. *Bromo-acetyl-propionic ether* mixed with an alcoholic solution of phenyl-hydrazine forms $CH_3.C(N_2HPh).CH:CH.CO_2Et$ [117·5°], which on reduction with tin and HCl forms methyl-indole carboxylic acid (Bender). Bromo-acetyl-propionic acid forms $CH_3.C(N_2HPh).CH:CH.CO_2H$ [157°] (Decker, *B.* 21, 2937). — 43. *Di-chloro-maleïc imide* at 100° forms $C_4O_2(N_2H_2Ph)_2NH$ crystallising from acetone in orange-red needles (Ciamician, *B.* 22, 2495).—44. *Amides* react thus: $N_2H_3Ph + R.CO.NH_2 = NH_3 + R.CO.N_2H_2Ph$ (Just, *B.* 19, 1201).—45. *Carbamic ether* forms, on heating, di-phenyl-carbazide $CO(NH.NHPh)_2$ [151°] (Skinner a. Ruhemann, *B.* 20, 3372).—46. Reduces *alloxan* to alloxantin, N and benzene being formed (Pellizzari, *G.* 17, 254). In this reaction the first product is the compound $CO{<}\begin{matrix}NH.CO\\NH.CO\end{matrix}{>}C(OH).N_2H_2Ph$ (Skinner a. Ruhemann, *C. J.* 53, 550).—47. *Parabanic acid* with phenyl-hydrazine hydrochloride and NaOAc yields $C_{15}H_{20}N_6O_4$ [170°], which on boiling with water forms $NH_2.CO.NH.CO.CO.N_2H_2Ph$ [215°] (S. a. K.).—48. *Urea* heated with phenyl-hydrazine hydrochloride at 160° forms phenyl-urazole $NPh{<}\begin{matrix}NH.CO\\CO.NH\end{matrix}$ [263°]. — 49. Reduces *nitroso-aniline* to *p*-phenylene-diamine and $C_{12}H_{12}N_4O$ (Fischer, *B.* 21, 2610). —50. The acetate (2 mols.) acting on *nitroso-dimethyl-aniline* (3 mols.) forms $C_{14}H_{16}N_4O$ [103°]. An ethereal solution of phenyl-hydrazine converts nitroso-di-methyl-aniline into di-methyl-amido-benzene-azo-di-methyl-aniline and phenylene-di-methyl-diamine. In alcoholic solution there is formed $NHPh.C_6H_4.NMe_2$ [130°] which yields a nitrosamine $C_{14}H_{15}N_3O$ [116°] (O. Fischer, *B.* 21, 2609).—51. *Di-nitroso-acetone* (1 mol.) mixed with phenyl-hydrazine (1 mol.) in hot alcoholic solution forms $CH(NOH).C(N_2HPh).CH(NOH)$ [145°]. Di-nitroso-acetone boiled with excess of phenyl-hydrazine acetate forms $C_{15}H_{12}N_4$ crystallising in yellow plates [122°].—52. *Diazo-acetic ether* at 100° gives off N and forms a colourless compound [136°]. — 53. *p-Diazo-benzene sulphonic acid* forms the compound $N_3C_6H_4.SO_3N_2H_4Ph$ aq crystallising in plates (Griess, *B.* 20, 1528).—54. *Di-acetyl-succinic ether* fused with phenyl-hydrazine at 100° forms $CO_2Et.CH(CMe:N_2PhH).CHAc.CO_2Et$ [91°] and $CO_2Et.CH(CMe:N_2PhH).CH(CMe:N_2PhH).CO_2Et$ which on heating with toluene at 180° gives di-oxy-di-phenyl-di-methyl-dipyrazyl (*q.v.*). — 55. *Dioxims* form additive compounds; *e.g. glyoxim* yields $C_2H_2(NOH)_2N_2H_3Ph$ [110°], *di-phenyl-glyoxim* yields $C_2Ph_2(NOH)_2N_2H_3Ph$ [150°], while the *di-oxim of (β)-naphthoquinone* forms $C_{10}H_6(NOH)_2N_2H_3Ph$ [138°] (Polonowsky, *B.* 21, 182).—56. *Phloroglucin* kept for five days with an alcoholic solution of phenyl-hydrazine in the cold forms $C_6H_3(OH)(N_2H_2Ph)_2$ [144°] which may be oxidised by $FeCl_3$ to $C_6H_3(OH)(N_2Ph)_2$ [177°] (Baeyer *B.* 22, 2891).—57. *Thio-acetoacetic ether* forms $S(CH{<}\begin{matrix}CO-NPh\\CMe:N\end{matrix})_2$ [183°], together with the compounds $NHPh.N:C{<}\begin{matrix}CO-NPh\\CMe:N\end{matrix}$ [156°], $S_2(CH{<}\begin{matrix}CO-NPh\\CMe:N\end{matrix})_2$ and di-oxy-di-phenyl-di-methyl-dipyrazyl (Sprague, *C. J.* 59, 332).—5 *Cyanogen* passed into an emulsion of pheny hydrazine in cold water forms the dicyanide (*infra*). - 59. *Cyanogen* passed into an alcoholi solution forms $PhN_2H_2.C(NH).C(NH).N_2PhH$ [225°], crystallising in white plates (fro alcohol). The same compound is formed by th action of phenyl-hydrazine on cyananiline. I gives a rose-red colour with alcoholic NH Conc. H_2SO_4 is coloured indigo-blue. Dry HC forms the hydrochloride $C_{14}H_{16}N_6 2HCl$ [188 Dilute HCl forms $PhN.NH.CO.C(NH).NHNHP$ [180°].—60. *Cyananiline* in chloroform solutio forms, after boiling, matted needles of the com pound $C_{21}H_{23}N_8Cl_2$ [200°-212°]. This body i perhaps $(PhH_2N_2.CHCl.C_{14}H_{15}N_6)2HCl$ (Senf *J. pr.* [2] 35, 533).—61. PCl_3 in ether form amorphous $NHPh.N:P.NH.NHPh$ converted b water into $(NHPh.NH)_2POH$, a yellowish-whit powder [92°] which reduces Fehling's solutio in the cold (Michaelis a. Oster, *A.* 270, 126) This body is split up by acids into phenyl-hydrazine and H_3PO_3, but is attacked by alkali with difficulty. Benzoic aldehyde produce $NPhH.N:CHPh$ and H_3PO_3.—62. $POCl_3$ forms $PO(NH.NHPh)_3$ [196°], easily decomposed by acids and alkalis (Michaelis, *A.* 270, 135).—63. $PSCl_3$ forms, in like manner, $PS(NH.NHPh)_3$ [154°].—64. $AsCl_3$ forms $(N_2PhH_3)_3AsCl_3$, an amorphous powder decomposed at 236°.—65. BCl_3 forms, in like manner, $(N_2PhH_3)_3BCl_3$, v. sol. water, decomposed at 242°.—66. $C_6H_5PCl_2$ in ether forms $NHPh.N.PC_6H_5$ [152°] crystallising from EtOAc in plates (Michaelis a. Oster, *A.* 270, 129). It reduces hot Fehling's solution, and is split up by acids into $PhPO_2H_2$ and phenyl-hydrazine.

Salts.—B'HCl. Plates, m. sol. water. Got by ppg. an alcoholic solution of the base by HCl, and washing the pp. till it is colourless.—B'HBr. Needles (from water).—$B'_2H_2SO_4$. Plates, v. sol. water.—$B'C_6H_3N_3O_7$. Yellow needles.—$B'_2H_2C_2O_4$. Plates.—**Benzene sulphinate**; [131°] (Escales, *B.* 18, 895).—**Di-nitro-(α)-naphthol sulphonate**: light-brown needles, sl. sol. hot water (Richardson, *C. N.* 58, 39).—**Sulphocyanide**: sparingly soluble plates. Changes at 160°-170° into phenyl-thio-semicarbazide. — $B'H_3PO_3$. [118°] (Michaelis, *A.* 270. 127, 133).—$B'_2H_3PO_3$. [121°]. — $B'C_6H_5PH_2O_2$. [135°].

Sodium derivative $C_6H_5NNa.NH_2$. Formed by dissolving 8 g. of sodium in 70 g. of warm phenyl-hydrazine. The H evolved reduces some of the phenyl-hydrazine to NH_3 and aniline; when the reaction is complete the aniline and excess of phenyl-hydrazine are distilled off by heating the product in an oil-bath to 200°-210° (not higher) in a current of H. It is a yellow hygroscopic powder. When finely divided it sometimes takes fire in the air. Decomposed by water into phenyl-hydrazine and NaOH. Readily reacts with alkyl haloids, giving unsymmetrical phenyl-alkyl-hydrazines (Michaelis, *B.* 19, 2448; *A.* 252, 266).

Formyl derivative NHPh.NH.CHO. [145°]. Formed by heating formamide with phenyl-hydrazine at 180°. White scales.

Acetyl derivative NHPh.NHAc. [128·5°]. Formed by heating phenyl-hydrazine with HOAc or acetamide (Fischer, *A.* 190, 129; Just. *B.*

19, 1201). Formed also from the sodium- derivative and Ac$_2$O at 0° (Michaelis a. Schmidt, *A.* 252, 301). Six-sided prisms, sl. sol. cold water.

Di-acetyl derivative NPhAc.NHAc. [108°]. Formed from NPhNa.NH$_2$ and AcCl in ether. Tables or needles, v. e. sol. alcohol. Completely reduces hot Fehling's solution.

Chloro-acetyl derivative NHPh.NH.CO.CH$_2$Cl. [115°]. Formed from the base and CH$_2$Cl.COCl in ether (Gattermann, *B.* 25, 1081).

Propionyl derivative NHPh.NH.CO.Et. [158°] (Freund a. Goldschmidt, *B.* 21, 2161).

n-Butyryl derivative. [114°]. Scales, v. sol. ether (Michaelis a. Schmidt, *A.* 252, 308).

Isovaleryl derivative NHPh.NH.CO.CH$_2$Pr. [101°]. Formed from the base and aceto-valeric anhydride (Autenrieth, *B.* 20, 3190). Plates, v. sl. sol. cold ligroïn.

Hexoyl derivative. [117°]. Needles.

s-Benzoyl derivative NHPh.NHBz. [169°]. Formed from phenyl-hydrazine by adding BzCl in ether at 0° (Fischer, *A.* 190, 125), or by heating with benzamide (Just, *B.* 19, 1203). Formed also by warming phenyl-hydrazine with BzCy (Hausknecht, *B.* 22, 329). Prisms, sl. sol. hot water. Yields NPhMe.NHBz on methylation. Reduces HgO. Phthalic anhydride at 180° forms an addition-compound C$_{21}$H$_{16}$N$_2$O$_4$ [172°], crystallising from alcohol in prisms. It is probably CO$_2$H.C$_6$H$_4$.CO.NPh.NHBz. At 250° it splits up into benzoic acid and (*β*)-phthalyl-phenyl-hydrazine

$$C_6H_4{:}C_2O_2\left\langle\begin{array}{l}NH\\ \,|\\ NPh\end{array}\right.$$

u-Benzoyl derivative NPhBz.NH$_2$. [70°]. A product of the action of BzCl in benzene on NPhNa.NH$_2$ at 0° (Michaelis a. Schmidt, *B.* 20, 43, 1718; *A.* 252, 310). Needles (from water). Reduces hot Fehling's solution but not HgO. Conc. HCl at 150° gives HOBz and phenyl-hydrazine. HNO$_2$ forms in acid solution benzanilide and N$_2$O, but in neutral solution it forms N$_3$Ph and HOBz. Reacts like phenyl-hydrazine with aldehydes and ketones; thus acetone yields NPhBz.N:CMe$_2$ [115·5°], acetophenone forms NPhBz.N:CMePh [124°], and benzoic aldehyde gives NPhBz.N:CHPh [122°]. Salts.—B'HCl. [202°]. Needles, m. sol. HClAq. —NPhBz.NHNa. White pp., decomposed by water.—B'$_2$H$_2$SO$_4$. [191°]. Needles, sl. sol. cold water.—B'HNO$_3$. [145°].—B'C$_6$H$_3$N$_3$O$_7$. [122°].

Di-benzoyl derivative NPhBz.NHBz. [178°] (Fischer, *A.* 190, 128; M. a. S.). Prisms, v. sl. sol. water, sol. alkalis. On methylation it yields NPhBz.NHBz.—NPhBz.NBzNa: plates.

Benzoyl-acetyl derivative NPhBz.NHAc. [153°]. Got from NPhBz.NH$_2$ and Ac$_2$O. Needles (from dilute alcohol).

p-Nitro-benzoyl derivative NHPh.NH.CO.C$_6$H$_4$.NO$_2$. [198°]. Formed from phenyl-hydrazine and C$_6$H$_4$(NO$_2$)CN (Hausknecht, *B.* 22, 328). Yellowish-red needles.

o-Amido-benzoyl derivative. [170°]. Got by warming phenyl-hydrazine with an alcoholic solution of isatoic acid (Meyer, *J. pr.* [2] 33, 20). Yellow needles, v. sl. sol. ether.

m-Amido-benzoyl derivative NHPh.NH.CO.C$_6$H$_4$.NH$_2$. [151°]. Formed by heating phenyl-hydrazine (1 mol.) with *m*-amido-benzoic acid (1 mol.) at 165° (Pellizzari, *G.* 16, 200). Scales, insol. cold alkalis, sol. acids.

Amido-toluyl derivative [3:6:1] C$_6$H$_3$Me(NH$_2$).CO.N$_2$H$_2$Ph. [198°]. Formed from methyl-isatoic acid and phenyl-hydrazine (Panaotovitch *J. pr.* [2] 33, 68). Prisms (from chloroform), sl. sol. ether.

Phenyl-acetyl derivative N$_2$H$_2$Ph.CO.CH$_2$Ph. [169°]. Got by heating phenyl-acetic acid with phenyl-hydrazine at 150° (Bülow, *A.* 236, 196). Needles (from alcohol), sl. sol. water.

Cinnamoyl derivative N$_2$H$_2$Ph.CO.C$_2$H$_2$.Ph. [258°]. Got by heating cinnamic acid with phenyl-hydrazine at 190° (Knorr, *B.* 20, 1108). Forms, on distillation, a compound C$_{15}$H$_{12}$N$_2$O [258°], crystallising in needles with green fluorescence.

Oxalyl derivative C$_2$O$_2$(N$_2$H$_2$Ph)$_2$. [278°]. Described in vol. iii. p. 655.

Ethyl-malonyl derivative CHEt(CO.N$_2$H$_2$Ph)$_2$. [233°]. Got by heating ethyl-malonic amide with phenyl-hydrazine at 220° (Freund a. Goldsmith, *B.* 21, 1242). Needles (from HOAc). Converted by COCl$_2$ into C$_{19}$H$_{16}$N$_4$O$_4$ [113°].

Succinyl derivative C$_2$H$_4$:C$_2$O$_2$:(N$_2$H$_2$Ph)$_2$. [218°]. Formed from succinyl chloride (1 mol.) and phenyl-hydrazine (2 mols.). Formed also by heating C$_2$H$_4$:C$_2$O$_2$:S with phenyl-hydrazine and HOAc (Zanetti, *Rend. Accad. Linc.* [4] 5, i. 225). Plates (from HOAc) (Freund, *B.* 21, 2456; Fischer a. Passmore, *B.* 22, 2734). When succinic anhydride is heated with phenyl-hydrazine at 160° there is formed C$_2$H$_4$:C$_2$O$_2$:N.NHPh [155°], which yields a nitros-amine C$_2$H$_4$:C$_2$O$_2$:N$_2$Ph.NO [84°] (Hötte, *J. pr.* [2] 35, 293).

(a)-*Phthalyl derivative* C$_6$H$_4$:C$_2$O$_2$:N.NHPh. [179°]. Formed from phenyl-hydrazine and phthalyl chloride in ether (Pickel, *A.* 232, 233). Formed also by heating phenyl-hydrazine (1 mol.) with phthalimide (1 mol.) at 120° (Pellizzari, *G.* 16, 203; Just, *B.* 19, 1204); or with phthalic anhydride (1 mol.) at 150° (Hötte, *J. pr.* [2] 33, 99; 35, 268). Prepared by boiling an alcoholic solution of phthalic anhydride with phenyl-hydrazine. Colourless needles (from alcohol), insol. water and alkalis. Conc. H$_2$SO$_4$ forms a violet solution, turning brown. *Reactions.*—1. Converted by boiling alcoholic *potash* into N$_2$H$_2$Ph.CO.C$_6$H$_4$.CO$_2$H [166°], an acid of which the benzoyl derivative NHPh.NBz.CO.C$_6$H$_4$.CO$_2$H [172°] is formed by heating NHPh.NHBz with phthalic anhydride at 180°.—2. Boiling aqueous KOH or HClAq at 150° splits it up into phthalic anhydride and phenyl-hydrazine.—3. *Benzoyl chloride* at 160° forms C$_6$H$_4$:C$_2$O$_2$:N.NPhBz [193°].—4. *Nitrous acid* passed into its solution in diluted HOAc forms the nitramine C$_6$H$_4$:C$_2$O$_2$:N.NPh.NO$_2$ [148°]; but in boiling HOAc it forms the di-nitro- derivative C$_{14}$H$_8$N$_4$O$_6$ [182°]. Nitrous acid passed into phthalyl-phenyl-hydrazine suspended in ether forms the nitrosamine C$_6$H$_4$:C$_2$O$_2$:N.NPh(NO) [154°].—5. Alcoholic NH$_3$ at 80° forms unstable NH$_2$.CO.C$_6$H$_4$.CO.NH.NHPh [146°], which decomposes at 170° into NH$_3$ and (*β*)-phthalyl-phenyl-hydrazine [210°].

(β)-*Phthalyl derivative* $C_6H_4{:}C_2O_2{<}\begin{matrix}NH\\NPh\end{matrix}$. [210°]. Formed at the same time as the (α)-isomeride by heating phenyl-hydrazine with phthalimide or phthalic anhydride, being the chief product when the temperature is above 163° (Pellizzari, *G.* 16, 204; 17, 278; Hötte, *J. pr.* [2] 35, 284). Monoclinic tablets (from benzene) or prisms (from alcohol), v. sol. alkalis. Ammoniacal $AgNO_3$ ppts. $C_6H_4{:}C_2O_2{:}N_2PhAg$.

Reactions.—1. NaOMe and MeI at 100° form $C_6H_4{:}C_2O_2{:}N_2PhMe$ [125°], which is decomposed by conc. HClAq into phthalic acid and NHPh.NHMe.—2. KOEt and EtI give $C_8H_4O_2{:}N_2PhEt$ [106°].—3. BzCl at 200° forms $C_8H_4O_2{:}N_2PhAc$ [122°].

Phthalyl derivative $C_6H_4(CO.NH.NHPh)_2$. [191°]. Formed by heating phenyl-hydrazine (2 mols.) with phthalic anhydride (1 mol.) at 150° (H.). White tables. At 170° it gives the (β)-phthalyl derivative [210°].

Nitrosamine $NH_2.NPh.NO$. Formed by adding $NaNO_2$ to an aqueous solution of phenyl-hydrazine hydrochloride at 0° (Fischer, *A.* 190, 92). Pale-yellow plates. Very poisonous. Converted by hot alcoholic potash into diazobenzene-imide. Alcoholic HCl acts in like manner. Exhibits Liebermann's reaction.

Dicyanide $C_8H_8N_4$ *i.e.* $NH_2.NPh.C(NH).CN$? Separates as colourless flakes when cyanogen is passed into an emulsion of phenyl-hydrazine and cold water (Bladin, *B.* 18, 1544). Monoclinic laminæ, v. sol. alcohol and ether. Decomposes above 160°. Yields a formyl derivative $C_8H_7(CHO)N_4$ [193°].

Reactions.—1. By heating with Ac_2O it is converted into $C_{10}H_8N_4$ [108°], which on saponification yields an acid $C_{10}H_9N_3O_2$ [177°], which on heating loses CO_2, leaving oily $C_9H_9NO_3$ (c. 240°).—2. By heating with *propionic anhydride* it is converted into $C_{11}H_{10}N_4$ [38°].—3. By treatment with *nitrous acid*, followed by boiling with water, it yields $C_8H_5N_5$, crystallising in needles [56°], v. sl. sol. water.—4. *Acetic aldehyde* in alcohol and HCl give $CH_3.CH{:}N.NPh.C(NH).CN$ [96·5°], crystallising in pale-yellow plates, v. e. sol. alcohol and ether, insol. water; converted by alcoholic $AgNO_3$ into phenyl-methyl-triazole carboxylic nitrile [109°] (Bladin, *B.* 25, 184).—5. *Benzoic aldehyde* forms the corresponding $CHPh{:}N.NPh.C(NH).CN$ [129·5°], crystallising from alcohol in prisms, oxidised by $FeCl_3$ to $C_{15}H_{10}N_4$ [156°] (Bladin, *B.* 22, 796).—6. *Pyruvic acid* in alcohol forms the above phenyl-methyl-triazole carboxylic nitrile on warming gently (Bladin, *B.* 19, 2598).—7. Boiling *acetoacetic ether* forms the compound $CO_2H.CH_2.CMe{:}N.NPh.C(NH).CN$ [209°], the oily ether of this acid, and phenyl-methyl-triazole carboxylic nitrile $N{\ll}\begin{matrix}CMe.N\\NPh.C.CN\end{matrix}$ [109°] (Bladin, *B.* 25, 190). The acid forms the salts KA′ and NH_4A', and is converted by nitrous acid into $CO_2H.C(NOH).CMe{:}N.NPh.C(NH).CN$ [218°], and by potash into the compound $CO_2H.CH_2.CMe{:}N.NPh.CO.CN$ [188°], from which potassium nitrite and HClAq form $CO_2H.C(NOH).CMe{:}N.NPh.CO.CN$ [209°].

References.—AMIDO-, IODO-, NITRO-, and OXY PHENYL-HYDRAZINE.

u-Di-phenyl-hydrazine $NPh_2.NH_2$. [34·5°] (220° at 40 mm.) (Stahel, *A.* 258, 243). Formed by reducing di-phenyl-nitrosamine $NPh_2.NO$ in alcoholic solution with zinc-dust and HOAc (E. Fischer, *A.* 190, 174). Monoclinic tables (from ligroïn), partially decomposed on distillation into diphenylamine and NH_3. Conc. H_2SO_4 forms a deep-blue solution. Decomposed by nitrous acid into $NPh_2.NO$ and N_2O. Reduces HgO, forming in the cold crystalline tetra-phenyl-tetrazone $NPh_2.N{:}N.NPh_2$ [123°], but if the temperature rises the products are N and diphenylamine. Benzoic aldehyde forms $NPh_2.N{:}CHPh$ [122°]. With salicylic aldehyde, furfuraldehyde, glucose, mannose, galactose, and rhamnose it forms di-phenyl-hydrazides, melting at 139°, 90°, c. 162°, c. 155°, 157°, and 134° respectively.

Salts.—B′HCl. Needles, v. sl. sol. cold water.—$B'_2H_2SO_4$: needles, m. sol. dilute H_2SO_4.

Formyl derivative $NPh_2.NH.CHO$. [116·5°]. Formed by boiling the formyl derivative of phenyl-hydrazine with ammoniacal $CuSO_4$ (Gattermann, *B.* 25, 1075). Needles, sl. sol. hot water and ligroïn, v. sol. alcohol.

Acetyl derivative $NPh_2.NHAc$. [185°]. Formed by boiling NHPh.NHAc with HOAc and $Cu(OAc)_2$ (Tafel, *B.* 25, 413).

Propionyl derivative. [178°]. Needles.

Benzoyl derivative $NPh_2.NHBz$. [189°] (G.); [192°] (Fischer, *A.* 190, 178). Needles (from acetone), m. sol. alcohol.

Phthalyl derivative $C_8H_4O_2{:}N.NPh_2$. [155°]. Formed by heating di-phenyl-hydrazine with phthalic anhydride at 160° (Hötte, *J. pr.* [2] 35, 271).

s-Di-phenyl-hydrazine NHPh.NHPh. *Hydrazo-benzene.* Mol. w. 184. [131°]. H.C. 1,598,000 (from diamond) (Petit, *A. Ch.* [6] 17, 163). S. (alcohol) 5 at 16° (Moltschanowsky, *C. J.* 42, 965). Prepared by passing H_2S into a solution of azobenzene $Ph.N_2.Ph$ in alcoholic NH_3 (Hofmann, *Pr.* 12, 576). Formed also by reducing nitro-benzene with sodium-amalgam or zinc-dust (Alexejeff, *Z.* 1868, 497; Glaser, *A.* 142, 364). Laminæ, sl. sol. water, m. sol. alcohol and ether. Yields aniline and azobenzene on distillation.

Reactions.—1. HClAq converts it into the isomeric di-*p*-amido-diphenyl (benzidine). H_2SO_4 acts in like manner.—2. Readily *oxidised* to azobenzene, even by moist air.—3. *Nitrous acid*, passed into an alcoholic solution at 0°, yields a nitroso- compound which, when warmed, violently decomposes into NO and azobenzene (Baeyer, *B.* 2, 683).—4. On heating with BzCl it yields di-benzoyl-di-*p*-amido-diphenyl; formic acid gives di-formyl-di-*p*-amido-diphenyl (Stern, *B.* 17, 379); and phthalic anhydride yields di-phthalyl-di-amido-diphenyl (Bandrowski, *B.* 17, 1181).—5. Boiling *benzoic aldehyde* forms azobenzene, but benzoic aldehyde and $ZnCl_2$ gives $C_{12}H_8(N{:}CHPh)_2$ (Clève, *Bl.* [2] 45, 188). Benzoic aldehyde, heated with hydrazobenzene at 120°–150°, forms 'benzhydrazoïn' $CHPh{<}\begin{matrix}NPh\\NPh\end{matrix}$ [55°]. The *o*-nitro- derivative $C_6H_4(NO_2).CHN_2Ph_2$ of this body melts at 66°.—6. *Furfuraldehyde* forms

$C_4H_3O.CH<\begin{smallmatrix}NPh\\NPh\end{smallmatrix}$ [59°] (Cornelius a. Homolka, *B.* 19, 2240).—7. *Phenyl cyanate* (2 mols.) and some benzene at 150° forms the compound NHPh.CO.NPh.NPh.CO.NHPh [220°] (Goldschmidt a. Rosell, *B.* 23, 490).

Acetyl derivative NHPh.NPhAc. [159°]. Formed from *s*-di-phenyl-hydrazine and Ac_2O in the cold (Stern, *B.* 17, 380). Needles (from alcohol). Decomposed by heat into acetanilide and azobenzene.

Di-acetyl derivative NPhAc.NPhAc. [105°]. Formed from *s*-di-phenyl-hydrazine and Ac_2O (Schmidt a. Schultz, *B.* 12, 485; *A.* 207, 326). Yellowish trimetric crystals (from alcohol); *a:b:c* = ·67:1:·56, not affected by dilute HClAq.

Chloro-derivatives $C_6H_5NH.NHC_6H_4Cl$. [90°].—$N_2H_2(C_6H_4Cl[1:3])_2$ [91°].—$N_2H_2(C_6H_4Cl[1:4])_2$ [122°] (Claus a. Heumann, *B.* 13, 1181, 19, 1688; Laubenheimer, *B.* 8, 1624).

Bromo-derivative $C_6H_5.NH.NH.C_6H_4Br$. [115°]. Formed from benzene-azo-*p*-bromobenzene and alcoholic ammonium sulphide (Janowsky a. Erb, *B.* 20, 361). Tables. Converted by H_2SO_4 into bromo-benzidine.

Di-bromo- derivatives $N_2H_2(C_6H_4Br.)_2$. *o.* [82°]. *m.* [109°]. *p.* [130°] (J. a. E.; Gabriel, *B.* 9, 1406; Werigo, *A.* 165, 192).

Iodo- derivatives v. vol. iii. p. 41.

Nitro- derivatives v. vol. iii. p. 607.

Oxy- derivatives v. vol. iii. p. 743.

Chloro-nitro- derivative $NHPh.NHC_6H_3Cl(NO_2)$ [1:3:6]. [135°-140°]. Formed from chloro-di-nitro-benzene and phenyl-hydrazine in alcohol (Willgerodt a. Ferko, *J. pr.* [2] 37, 355). Red prisms.

p-Amido- derivative. The compound $NHPh.NH.C_6H_4.NHAc$ [146°] is got by treating $C_6H_5.N_2.C_6H_4NHAc$ with alcoholic ammonium sulphide (Schultz, *B.* 17, 463). Yellowish plates (from dilute alcohol). Re-oxidised to the azo- compound by air.

Di-m-amido- derivative $N_2H_2(C_6H_4.NH_2)_2$. [141°] (Gebek, *A.* 251, 193). Got by treatment of *m*-nitro-aniline with alcoholic potash and zinc-dust (Graeff, *A.* 229, 341), or with sodium-amalgam (Haarhaus, *A.* 135, 164). Golden needles (from alcohol). Yields $C_{12}H_9Br_5N_4$ [150°] and $C_{12}H_{12}Ac_2N_4$ [247°].—$B''H_2Cl_2$.—$B''H_2PtCl_6$.—$B''2HNO_3$.—$B''H_2SO_4$.—$B''H_2C_2O_4$. Prisms, v. sl. sol. water.

Di-p-amido- derivative. [145°]. Got by reducing $N_2(C_6H_4.NO_2)_2$ with alcoholic ammonium sulphide (Gerhardt a. Laurent, *A.* 75, 74; Lermontoff, *B.* 5, 232). Yellow crystals. Yields quinone on oxidation. — $B''H_2Cl_2$. — $B''2HNO_3$.

Di-diphenyl-hydrazine *v.* HYDRAZO-DIPHENYL.

PHENYL-HYDRAZINE *o*-CARBOXYLIC ACID $C_7H_8N_2O_2$ *i.e.* $NH_2.NH.C_6H_4.CO_2H$. *Hydrazido-benzoic acid.* Formed from *o*-amidobenzoic acid by diazotising and treating the product with Na_2SO_3 (E. Fischer, *B.* 13, 679; *A.* 212, 333). Needles, sol. hot water. Reduces Fehling's solution in the cold. — HA'HCl: needles, sol. hot water.

Anhydride $C_7H_6N_2O$. [242°]. Formed by heating the acid at 220°. Monoclinic plates (from alcohol); *a:b:c* = 1·072:1:·664; β = 75° 18'. Sublimes in white needles.—$NaC_7H_5N_2O$ *x*aq: silvery plates. — B'HCl: white needles. — $B'HgCl_2$: needles (from water). Yields an acetyl derivative $C_7H_4Ac_2N_2O$ [112°].

Phenyl-hydrazine *m*-carboxylic acid $N_2H_3.C_6H_4.CO_2H$. [186°]. Formed by the action of tin and HClAq on $C_6H_4(CO_2H).N{:}N.SO_3K$, which is got by warming the nitrate of *m*-diazobenzoic acid with aqueous K_2SO_3 (Griess, *B.* 9, 1657; Roder, *A.* 236, 164). Plates, sl. sol. hot Aq.

Reactions.—1. *Acetone* forms $C_{10}H_{12}N_2O_2$ [150°], which gives EtA' [91°].—2. *Benzoic aldehyde* forms $CHPh{:}N.NH.C_6H_4.CO_2H$ [172°].—3. *Pyruvic acid* reacts with formation of $CO_2H.CMe{:}N.NH.C_6H_4.CO_2H$ [208°], which forms whetstone-shaped crystals (containing aq), and gives EtA' [102°].—4. *Glucose*, heated with the hydrochloride and NaOAc, gives $C_{20}H_{22}N_4O_8$ [208°]. — 5. *Phenyl-thiocarbimide* forms the compound $C_{14}H_{13}N_3SO_2$ [205°].

Salts.—HA'HCl.—BaA'_2 4aq. Nodules.

Phenyl-hydrazine *p*-carboxylic acid $N_2H_3.C_6H_4.CO_2H$. [220°-225°]. Formed, in the same way as its isomerides, from *p*-amido-benzoic acid (Fischer, *A.* 212, 337). Needles or plates (from water).—HA'HCl: sl. sol. cold water.

***s*-Di-phenyl-hydrazine di-*o*-carboxylic acid** $C_{14}H_{12}N_2O_4$ *i.e.* $CO_2H.C_6H_4.NH.NH.C_6H_4.CO_2H$. Mol. w. 272. [205°]. Formed by reducing *o*-azoxy-benzoic acid with sodium-amalgam (Griess, *B.* 7, 1609; Homolka, *B.* 17, 1904). Small colourless plates. Oxidised by moist air to *o*-azobenzoic acid.

***s*-Di-phenyl-hydrazine di-*m*-carboxylic acid.** *Hydrazo-benzoic acid.* Formed by boiling *m*-azobenzoic acid with $FeSO_4$ and NaOHAq (Strecker, *A.* 129, 141). Insol. water, sl. sol. hot alcohol. In alkaline solutions it absorbs O, being oxidised to azobenzoic acid. Boiling conc. HClAq forms azobenzoic acid and amidobenzoic acid. Yields orange-red crystals of BaA''. On warming with $SnCl_2$ and HClAq at 100° it yields di-amido-diphenyl dicarboxylic acid and two other acids. One of these $C_{14}H_{10}N_2O_3$ crystallises from hot water in yellowish needles and forms BaA'_2 7aq and HA'HCl. The other acid $C_{14}H_{12}N_2O_4$ crystallises in yellow needles melting above 290°, and forms NaA' 4aq, BaA'_2 2aq, HA'HCl, HA'HBr, and $(HA')_2H_2SO_4$ (Kusseroff, *B.* 23, 913).

***s*-Di-phenyl-hydrazine di-*p*-carboxylic acid** $C_{14}H_{12}N_2O_4$. Formed by boiling *p*-azobenzoic acid with $FeSO_4$ and NaOHAq (Reichenbach a. Beilstein, *A.* 132, 137; Billfinger, *A.* 135, 152). Needles (from alcohol), easily oxidised in alkaline solution.

***s*-Di-phenyl-hydrazine tetra-carboxylic acid** $[1:4:2]C_6H_3(CO_2H)_2.NH.NH.C_6H_3(CO_2H)_2$ [2:1:4]. Formed by reducing azoxyterephthalic acid in alkaline solution with sodium-amalgam (Homolka a. Löw, *B.* 19, 1092). White crystalline pp., v. sol. alcohol and ether.

PHENYL-HYDRAZINE *m*-SULPHONIC ACID $C_6H_4(N_2H_3).SO_3H$. Formed from *m*-amidobenzene sulphonic acid by diazotisation and subsequent reduction by $SnCl_2$ at 0° (Limpricht, *B.* 21, 3409). Crystals (containing 2aq), sl. sol. cold water, nearly insol. alcohol. Converted in alcoholic solution by nitrous acid into $N_2C_6H_4SO_3H$.

Phenyl-hydrazine *p*-sulphonic acid $[1:4]C_6H_4(N_2H_3).SO_3H$.

Formation.—1. From diazobenzene *p*-sulphonic acid by warming with aqueous K_2SO_3 followed by HCl (E. Fischer, *A.* 190, 74).—2. By heating phenyl hydrazine sulphate with $ClSO_3H$ at 160° (Limpricht, *B.* 18, 2196).—3. Together with alcohol, by heating phenyl-hydrazine ethyl-sulphate at 160°.—4. By heating phenyl-hydrazine (1 pt.) with H_2SO_4 (6 pts.) at 100° (Gallinek a. Richter, *B.* 18, 3172).

Properties.—Needles (containing ½aq), sl. sol. water. By boiling with $CuSO_4$ it is neatly oxidised to N and benzene sulphonic acid. With acetoacetic ether and dilute (50 p. c.) HOAc at 155° it forms  $CMe\Big\langle\begin{matrix}N—N.C_6H_4.SO_3H\\CH_2.CO\end{matrix}$ (Möllenhoff, *B.* 25, 1849), which crystallises with aq.

Salts.—NaA′ 1½aq.—NH_4A'.—BaA'_2 5aq.—PbA'_2 2aq.—ZnA'_2 4aq: minute tables.

Phenyl-hydrazine ν-sulphonic acid. Potassium salt. $C_6H_5NH.NH.SO_3K$. Formed from diazobenzene nitrate and K_2SO_3 (Römer, *Z.* 1871, 481) and also by heating phenyl-hydrazine with $K_2S_2O_7$ (Fischer, *A.* 190, 97). Crystals (containing aq), sl. sol. cold water and alcohol. Oxidised by HgO to $C_6H_5.N_2.SO_3K$. Split up by boiling HClAq into phenyl-hydrazine and $KHSO_4$.

Phenyl-hydrazine disulphonic acid $NH_2.NH.C_6H_3(SO_3H)_2$. Two acids of this formula are got by further sulphonation of the *m*- and *p*- sulphonic acids respectively (L.). They both yield BaA″ and $BaH_2A''_2$.

s-Di-phenyl-hydrazine *m*-sulphonic acid $C_6H_5.NH.NH.C_6H_4.SO_3H$. Formed by heating the disulphonic acid with water at 200° for 3 days (Limpricht, *B.* 11, 1048). Yellow needles (containing 2½aq). — KA′ 4aq. — PbA'_2 3aq. — BaA'_2 4aq: yellow plates, v. sol. water.

Chloride $C_{12}H_{11}N_2SO_2Cl$. [240°].

Di-bromo- derivative $C_6H_4Br.NH.NH.C_6H_3Br.SO_3H$. Formed as a by-product in the oxidation of $C_6H_2Br_2(NH_2)SO_3H$ [1:3:6:4] by $KMnO_4$ (Limpricht, *B.* 18, 1425).—KA′ aq: long needles.

s-Di-phenyl-hydrazine di-*m*-sulphonic acid $N_2H_2(C_6H_4.SO_3H)_2$. S. ·079 at 22°. Formed by reduction of nitro-, azo-, or azoxy-benzene-sulphonic acid (Limpricht, *B.* 11, 1048; 21, 3409; 23, 1057; Bruhnemann, *A.* 202, 344; Mahrenholz a. Gilbert, *A.* 202, 337; Neumann, *B.* 21, 3419). White needles, v. e. sol. water, almost insol. alcohol and ether. Readily reduces ammoniacal $AgNO_3$ and Fehling's solution. HClAq immediately forms benzidine disulphonic acid.—K_2A'' aq.—BaA″ 2aq.

Amide $NH(C_6H_4.SO_2NH_2).NH.C_6H_4.SO_2NH_2$. [248°]. Formed by reducing $N_2(C_6H_4.SO_2NH_2)_2$ with zinc-dust and NH_3Aq or HOAc (Limpricht a. F. Meyer, *A.* 268, 132). White needles (from 50 p.c. acetic acid), almost insol. water, ether, and toluene. Reduces ammoniacal $AgNO_3$ forming a mirror. HClAq converts it into the amide of diamido-diphenyl (benzidine) disulphonic acid, *m*-amido-benzene sulphonic amide and $N_2(C_6H_4.SO_2NH_2)_2$. — $N_2H_2(C_6H_4.SO_2NHK)_2$ 1½aq. Thin needles or plates quickly oxidised by air.—$N_2H_2(C_6H_4.SO_2NHNa)_2$ 2½aq: needles.

s-Di-phenyl-hydrazine di-*p*-sulphonic acid $N_2H_2(C_6H_4.SO_3H)_2$. Obtained, in the same way as the preceding acid, from amido-benzene *p*-sulphonic acid.—$BaH_2A''_2$.—BaA″: crystalline.

Isomeride.—*V.* Benzidine tetrasulphonic acid, vol. i. p. 174.

DI-PHENYL-HYDRAZINE ν-DI-THIO-CARBOXYLIC ACID $NPh_2.NH.CS.SH$. [c. 109°]. Formed by dissolving $NPh_2.NH_2$ in CS_2 (Stahel, *A.* 258, 249). Golden prisms, v. sol. alcohol, insol. water.

s-Di-phenyl-hydrazine di-*m*-thiosulphonic acid $N_2H_2(C_6H_4.SO_2SH)_2$. Formed, together with $N_2(C_6H_4.SO_2.SH)_2$, by adding $N_2(C_6H_4.SO_2Cl)_2$ to a cold saturated solution of $Ba(SH)_2$ (Limpricht, *B.* 18, 1470; *A.* 220, 354). White amorphous pp., becoming sticky on boiling with water. Oxidised by $KMnO_4$ to $N_2(C_6H_4.SO_3H)_2$. — BaA″ 2aq: minute needles, sl. sol. cold water.

TRI-PHENYL-HYDRAZOÏN is *Benzhydrazoïn*, *v.* *s*-Di-phenyl-hydrazine, *Reaction* 5.

DI-PHENYL-HYDROQUINONE $C_{18}H_{14}O_2$ *i.e.* $C_6H_2Ph_2(OH)_2$ [5:2:4:1]. [219°]. Formed by reducing di-phenyl-quinone with aqueous SO_2 (Müller a. Pechmann, *B.* 22, 2131). Colourless cubes (from dilute alcohol).

PHENYL-IMESATIN *v.* Isatin.

PHENYL-IMIDO-DIACETIC ACID $NPh(CH_2.CO_2H)_2$. [150°-155°]. A product of the action of aniline on chloro-acetic acid (P. Meyer, *B.* 14, 1325; Hausdörfer, *B.* 22, 1796). Formed also by heating phenyl-amido-acetic acid with chloro-acetic acid and NaOAc at 120°-130° (H.). Needles, v. sol. hot water and alcohol. $NPhH_3A'$. Needles (from alcohol). Decomposes at 151°.

Mono-anilide $CO_2H.CH_2.NPh.CH_2.CO.NHPh$. [213°]. Formed together with the dianilide by heating the acid with aniline at 175°. Needles. Its ether $CO_2Et.CH_2.NPh.CH_2.CO.NHPh$ [122°] is got by heating the anilide of phenyl-amido-acetic acid (*q.v.*) with ether and NaOAc at 140°.

Di-anilide $NPh(CH_2.CO.NHPh)_2$. [218°]. Needles, v. sl. sol. alcohol.

TRI-PHENYL-TRI-IMIDO-BENZENE $C_{24}H_{21}N_3$ *i.e.* $C_6H_3(NHPh)_3$. [242°]. Formed by warming $C_6H_6Cl_6$ with aniline (Mohr, *M.* 11, 22). Golden plates, v. sol. chloroform, insol. water and alcohol. Conc. H_2SO_4 gives a dark-blue colour changed to violet by potash.

PHENYL-IMIDO-BENZYL-MALONIC ETHER $C_6H_5.C(NPh).CH(CO_2Et)_2$. [75°]. Formed, together with $(C_6H_5.C(NPh))_2C(CO_2Et)_2$, by the action of sodium malonic ether on the compound $C_6H_5.CCl:NPh$ (Just, *B.* 18, 2624). Decomposes at 150° into alcohol and oxy-phenyl-quinoline carboxylic ether.

DI-PHENYL IMIDO-DI-ETHYL DISULPHONE $NH(CH_2.CH_2.SO_2.C_6H_5)_2$. [78°]. Got by heating $C_2H_4(SO_2.C_6H_5)_2$ with NH_3Aq is sealed tubes (Otto, *J. pr.* [2] 30, 324). Triclinic plates (from alcohol).—Nitrate: [190°].—B′HCl. [193°].—$B'_2H_2PtCl_6$: plates, sl. sol. water.

PHENYL-IMIDO-METHENYL-*o*-AMIDO-PHENOL  $C_6H_4\Big\langle\begin{matrix}NH\\O\end{matrix}\Big\rangle C:NPh$. [c. 230°]. Formed by heating  $C_6H_4\Big\langle\begin{matrix}NH\\O\end{matrix}\Big\rangle CO$ with aniline at 210° (Von Chelmicki, *J. pr.* [2] 42, 440). Needles, insol. water, sl. sol. cold alcohol.

DI-PHENYL-DI-IMIDO-NAPHTHOL *v.* (β)-Naphthoquinone, *Reaction* 5.

PHENYL-IMIDO-DINAPHTHYL *v.* Phenyl dinaphthylene amine.

PHENYLIMIDO-PHENYL-METHYL-THI-ZOLE DIHYDRIDE $NPh{<}\begin{smallmatrix}C(NPh).S\\CMe=CH\end{smallmatrix}$. 138°]. Formed from di-phenyl-thio-urea and hloro-acetone (Traumann, *A.* 249, 51). Yel- wish prisms, insol. water, v. sol. ether.

DI-PHENYL-DI-IMIDO-DI-PHENYL-IAZTHIOLE TETRAHYDRIDE $C_{28}H_{20}N_4S$ *i.e.* ${<}\begin{smallmatrix}C(NPh).NPh\\C(NPh).NPh\end{smallmatrix}$. [131°]. Got by oxidising di-henyl-thio-urea with H_2O_2 (Hector, *B.* 23, 357).

PHENYL-IMIDO-PROPIONIC ACID $H_3.C(NPh).CO_2H$. *Anilpyruvic acid.* [122°]. ormed from aniline and pyruvic acid in ether Böttinger, *B.* 16, 1924; *A.* 188, 336; 263, 126). rystals, v. sol. water. Decomposed by boiling ater. Br yields $C_{15}H_{12}Br_3N_2O_2$ [264°].

Isomeride *v.* IMIDO-PHENYL-PROPIONIC ACID.

PHENYL-IMIDO-SUCCINIC ACID $O_2H.CH_2.C(NPh).CO_2H$. [150°]. Formed by ne action of dilute (1 p.c.) $KMnO_4$ on 'pyranil-yroic' acid (Anschütz, *B.* 22, 738; *cf.* Reissert, . 21, 1942). Decomposed on fusion.

PHENYL-IMIDO-THIAZOLE DIHYDRIDE $(NPh){<}\begin{smallmatrix}S-CH\\NH.CH\end{smallmatrix}$. [124°]. Formed from $H_2Cl.CHCl.OEt$ and phenyl-thio-urea (Näf, *A.* 5, 125). White needles, sol. alcohol. Yields nitrosamine $C_9H_7(NO)N_2S$ [58°].

Di-phenyl-imido-thiazole dihydride $(NPh){<}\begin{smallmatrix}S-CH\\NPh.CH\end{smallmatrix}$. [105°]. Formed from di-chloro-di-ethyl oxide and di-phenyl-thio-urea.

DIPHENYLINE *v.* DI-AMIDO-DIPHENYL.

PHENYL-INDAZINE $C_{13}H_{10}N_2$ *i.e.* $C_6H_4{<}\begin{smallmatrix}N\\CH\end{smallmatrix}{>}NPh$. [84°]. (345° uncor.). Formed by reducing *o*-nitro-benzyl-aniline with tin and HClAq (Paal, *B.* 23, 2640; 24, 961). Needles (from alcohol). Not affected by distillation over red-hot zinc-dust. Reduced to a dihydride [98°] by adding Na to its alcoholic solution. Yields a methylo-iodide B'MeI [188°].

PHENYL-INDOLE $C_6H_4{<}\begin{smallmatrix}CH\\NPh\end{smallmatrix}{>}CH$. (327° i.V.). Formed by heating its carboxylic acid [176°] (Fischer a. Hess, *B.* 17, 567; Pfülf, *A.* 239, 221). Oil, v. sol. alcohol. Its solution in HClAq colours pine-wood intensely violet.

Phenyl-indole $C_6H_4{<}\begin{smallmatrix}CH\\NH\end{smallmatrix}{>}CPh$. *Methyl-phenanthridine.* [186°]. (above 360°).

Formation.—1. By boiling ω-bromo-aceto-phenone or phenyl-ω-amido-acetophenone with aniline (Möhlau, *B.* 14, 173; 15, 2480; 18, 165). 2. By heating the phenyl-hydrazide of aceto-phenone or of phenyl-acetic aldehyde with $ZnCl_2$ at 180° (Fischer, *B.* 19, 1565; 21, 1071; *A.* 236, 135).—3. By passing benzylidene-*o*-toluidine through a red-hot tube (Etard, *Bl.* [2] 39, 531). 4. By the action of zinc-dust and NH_3Aq on $C_6H_4(NO_2).CH_2.CO.C_6H_5$ (Pictet, *B.* 19, 1065).

Properties.—Colourless plates, insol. water. May be sublimed. Colours pine-wood violet-blue. Yields $B'C_6H_3N_3O_7$ [127°]. Nitrous acid forms a nitroso-derivative $C_6H_4{<}\begin{smallmatrix}C(NO)\\NH\end{smallmatrix}{>}CPh$ [c. 258°], which yields B'HCl, $B'HNO_3$, and $NaC_{14}H_9N_2O$, and may be reduced to amido-phenyl-indole [174°].

Dihydride $C_{14}H_{13}N$. [46°]. Formed by boiling phenyl-indole with zinc-dust, alcohol, and HCl. Colours pine-wood orange. Yields a nitrosamine.

Phenyl-indole $C_6H_4{<}\begin{smallmatrix}CPh\\NH\end{smallmatrix}{>}CH$. [89°]. Formed by the action of alcoholic HCl on the phenyl-hydrazide of phenyl acetic aldehyde (Fischer, *B.* 21, 1811). White plates (from ligroïn), v. sol. alcohol. Converted by heating for fifteen minutes with $ZnCl_2$ into the preceding isomeride [186°]. Yields a picrate [107°] and a nitrosamine $C_6H_4{<}\begin{smallmatrix}CPh\\N(NO)\end{smallmatrix}{>}CH$ [61°] which gives Liebermann's reaction (Ince, *A.* 253, 37).

Di-phenyl-indole $C_6H_4{<}\begin{smallmatrix}CPh\\NH\end{smallmatrix}{>}CPh$. [123°]. Formed by heating the phenyl-hydrazide of de-oxybenzoïn with $ZnCl_2$ (Fischer, *B.* 19, 1566; *A.* 236, 136). Colourless crystals, v. sol. alcohol. Does not give the pine-wood reaction. Its picrate crystallises in dark-red needles.

Di-phenyl-indole $C_6H_4{<}\begin{smallmatrix}CH\\NPh\end{smallmatrix}{>}CPh$. (above 360°). Got by heating the *u*-di-phenyl-hydrazide of acetophenone with $ZnCl_2$ at 175° (Pfülf, *A.* 239, 223). Oil. Colours acidified pine-wood bluish-violet.

PHENYL-INDOLE CARBOXYLIC ACID $C_{15}H_{11}NO_2$ *i.e.* $C_6H_4{<}\begin{smallmatrix}C(CO_2H)\\N(C_6H_5)\end{smallmatrix}{>}CH$. [176°]. Formed by heating the di-phenyl-hydrazide of pyruvic acid with HOAc and HClAq (E. Fischer, *B.* 17, 567). Needles, v. sl. sol. water, v. sol. alcohol. NaOCl in the cold forms phenyl-ψ-isatin $C_6H_4{<}\begin{smallmatrix}CO\\NPh\end{smallmatrix}{>}CO$. [134°] (Pfülf, *A.* 239, 222).

PHENYL INDOXAZINE $C_6H_4{<}\begin{smallmatrix}CH\\O\end{smallmatrix}{>}N$. [84°]. Got from *o*-bromo-benzophenone and an alkaline solution of phenyl-hydrazine (Cathcart a. V. Meyer, *B.* 25, 1498). Large crystals.

PHENYL-INDULINE $C_{24}H_{17}N_3$ *i.e.* $\begin{smallmatrix}CH:CH——C:N\\C(NPh).CH:C.NPh\end{smallmatrix}{>}C_6H_4$. [231°]. Mol. w. (by Raoult's method) 320–370 (calc. 347). Formed from amido-phenyl-induline [152°] by treatment with nitrous acid (Fischer a. Hepp, *A.* 262, 257; 266, 263). Reddish tables, with blue reflex; v. sol. benzene, insol. ligroïn. Heated with HOAc (5 pts.) and HClAq (25 pts. of 20 p.c.) at 165° for six hours it forms: (*a*) $C_{24}H_{19}N_3O$ crystallising from benzene in steel-blue plates [218°], forming a brownish-red solution in HClAq, and converted by conc. HClAq at 200° into a compound $C_{18}H_{14}N_2O_2$; (*b*) the compound $C_{18}H_{14}N_2O_2$ [c. 280°] which crystallises from benzene or alcohol in brownish-yellow prisms or plates, and is both base and phenol. Its hydrochloride crystallises from conc. HClAq in prisms with green lustre; (*c*) *benzolindone* $C_{18}H_{12}N_2O$; (*d*) a body which dissolves in benzene with fiery brown fluorescence, and is perhaps carbazole-fluorindine (Fischer a. Hepp, *A.* 266, 249).

Benzolindone $C_{18}H_{12}N_2O$ *i.e.* $\begin{smallmatrix}CH:CH.C:N\\CO.CH:C.NPh\end{smallmatrix}{>}C_6H_4$. Formed by heating phenyl-induline with HOAc and HClAq at 160°–200° (Fischer a. Hepp, *A.* 266, 253). Lustrous brown plates, insol. alkalis, sol. dilute HClAq, forming a rose-coloured solution. Its solution in conc. H_2SO_4 is green. Yields phenazine on distillation with zinc-dust.

PHENYL IODIDE *v.* Iodobenzene.

PHENYL IODOMETHYL SULPHONE $C_6H_5.SO_2.CH_2I$. [64·5°]. Formed from benzene sulphinic acid, NaOEt, and CH_2I_2 at 100° (Michael a. Palmer, *Am.* 6, 253). Prisms (from alcohol). NaOEt at 75° gives phenyl-methyl sulphone and products of oxidation (Otto, *B.* 21, 654).

PHENYL-ITACONIC ACID $CHPh:C(CO_2H).CH_2.CO_2H$. [172°]. Formed by the action of Na or NaOEt on phenyl-paraconic acid (Fittig, *A.* 256, 68). Prisms, sl. sol. cold water. Yields phenyl-isocrotonic acid [179°] and γ-oxy-phenyl-butyric lactone [37°] when boiled with diluted H_2SO_4 (1:1). Br gives bromo-phenyl-paraconic acid $C_{11}H_9BrO_4$ [99°] and an isomeride [144°].—BaA″ 2½aq.—CaA″.—Ag_2A''.

Ethyl ether Et_2A''. (315° uncor.). Oil.

Di-PHENYL-KETONE *v.* Benzophenone.

Di-phenyl diketone *v.* Benzil.

Di-phenyl triketone $C_6H_5.CO.CO.CO.C_6H_5$. [70°]. (248° at 40 mm.). Formed by distilling $CBz_2Br.OAc$ *in vacuo.* Formed also by adding aqueous $NaNO_2$ to a solution of the mono-oxim in HOAc, and boiling (Pechmann, *B.* 22, 852; 23, 3375). Hygroscopic golden needles (from ligroïn), v. sol. all solvents. Give a blue colour with H_2SO_4 and benzene that contains thiophene.

Reactions.—1. Alkalis decompose it, forming benzoïn, benzoic acid, and $CBzPh(OH).CO_2H$ [118°].—2. *Phenyl-hydrazine* forms a phenyl-hydrazide $C_{21}H_{16}N_2O_2$ [c. 135°], benzene-azo-tri-phenyl-pyrazole  $C_6H_5.N_2.C<\begin{array}{l}CPh.NPh\\ CPh{:}N\end{array}$ [157°], and a third compound [223°].—3. *Aniline* gives rise to $CPh(NPh).C(OH)_2.COPh$ [100°] and $C(OH)_2(CPh:NPh)_2$ [148°].

Hydrate $Bz_2C(OH)_2$. [90°].

Mono-oxim $Bz_2C:NOH$. [146°]. Formed from Bz_2CH_2 and nitrous acid.

Tri-oxim $(C_6H_5.C(NOH))_2C:NOH$. [186°]. Formed from the triketone and hydroxylamine.

Di-phenyl tetraketone $C_6H_5.CO.CO.CO.CO.C_6H_5$. The hydrate [88°] of this body is formed by the action of conc. HNO_3 on phenyl-glyoxal (Abenius a. Söderbaum, *B.* 24, 3034).

DI-PHENYL-KETONE CARBOXYLIC ACID *v.* Benzoyl-benzoic acid.

Di-phenyl ketone dicarboxylic acid *v.* Benzophenone dicarboxylic acid.

Di-phenyl diketone *o*-carboxylic acid $C_6H_5.CO.CO.C_6H_4.CO_2H$. Formed by oxidising deoxybenzoïn *o*-carboxylic acid with alkaline $KMnO_4$ (Graebe, *B.* 21, 2003; 23, 1344). Occurs in a yellow modification [141·5°] and a white variety [125°–130°]. The yellow modification is nearly twice as sol. alcohol and chloroform as the white variety, and is converted into the white variety by dissolving in alkali and ppn. by acids. The white modification changes into the yellow one at 115°–125°.

Dicarboxylic acid *v.* Diphthalylic acid.

DI-PHENYL-KETOXIM *v. Oxim* of Benzophenone.

PHENYLLACTIC ACID *v.* Oxy-phenyl-propionic acid.

PHENYL-LACTIMIDE *v.* vol. i. p. 180.

PHENYL-LUTIDINE-CARBOXYLIC ACID *v.* Phenyl-di-methyl-pyridine-carboxylic acid.

PHENYL-LUTIDONE *v.* Oxy-phenyl-di-methyl-pyridine.

PHENYL-MALEÏC ACID $C_{10}H_8O_4$ *i.e.* $CO_2H.CPh:CH.CO_2H$. Formed by dissolving its anhydride in water and extracting with ether (Alexander, *A.* 258, 77). Prisms, m. sol. water. Begins to lose water below 100°.

Anhydride $\begin{array}{l}CH.CO\\ CPh.CO\end{array}\!>\!O$. [119·5°]. Formed by distilling phenyl-malic acid. Needles, insol. water, v. sol. chloroform and ether.

Di-phenyl-maleïc acid $CO_2H.CPh:CPh.CO_2H$. *Stilbene dicarboxylic acid.* Formed by saponification of its nitrile. Its ether is formed, together with di-phenyl-fumaric ether, by the action of Na on α-bromo-phenyl-acetic ether in ether (Reimer, *B.* 14, 1800; Rügheimer, *B.* 15, 1626). The free acid splits up at once, on liberation from its salts, into H_2O and anhydride. On distillation with lime it yields *s*-di-phenyl-ethylene.—K_2A'': needles, v. sol. water.—Ag_2A'': amorphous pp.—AgHA′: needles.

Ethyl ether Et_2A''. [54°]. Prisms.

Imide $C_{16}H_{10}O_2(NH)$. [213°]. Needles, almost insol. water, v. sol. alcohol.

Phenylimide $C_{16}H_{10}O_2(NPh)$. [175°]. Formed by heating the anhydride with aniline at 120° (Anschütz a. Bendix, *A.* 259, 63).

Nitrile CN.CPh:CPh.CN. *Dicyanostilbene.* [158°]. Formed by heating α-bromo-phenyl-acetonitrile alone or with alcoholic KCy (Reimer, *B.* 14, 1798). Plates (from benzene).

Isonitrile. [242°]. Occurs in small quantity in the preparation of the nitrile by heating the product of bromination of phenyl-acetonitrile. Golden needles (from alcohol). Yields an acid [222°] on saponification.

Anhydride  $\begin{array}{l}CPh.CO\\ CPh.CO\end{array}\!>\!O$. [155°]. (236° at 15 mm.). Formed by adding HCl to solutions of salts of the acid, or by heating di-phenyl-fumaric acid at 260° (Reimer, *B.* 13, 742). Trimetric needles (from dilute alcohol), *a*:*b*:*c* = ·693:1:·385, insol. water, sol. CS_2. May be sublimed. Its alkaline solution reduces $AgNO_3$. Not changed by NaOHAq into the fumaroid form (Delisle, *A.* 269, 91). NaOHAq (15 p.c.) at 100° forms a polymeride melting much above 250°, insol. water and other solvents.

Reactions.—1. Reduced in alcoholic solution by zinc-dust and HCl to a mixture of the two di-phenyl-succinic acids.—2. Fuming HNO_3 gives rise to an amorphous di-nitro- derivative $(C_6H_4(NO_2))_2C_4O_3$.—3. *p-Tolyl-acetic acid* forms $C_4Ph_2O_2:CH.C_7H_7$ [165°], crystallising in yellow needles.—4. *Phenyl-acetic acid* and NaOAc at 225° form  $\begin{array}{l}CPh.C(CHPh)\\ CPh.CO\end{array}\!>\!O$ [176°], which may be reduced by HI and P to benzyl-di-phenyl-maleïde  $\begin{array}{l}CPh.CH(CH_2Ph)\\ CPh.CO\end{array}\!>\!O$ [128°] (Gabriel a. Cohn, *B.* 24, 3228, 3854). The compound $C_4Ph_2O_2(CHPh)$ combines with Br, forming $C_4Ph_2BrO_2(CHBrPh)$ [154°], which splits up at 155°–160° into HBr and $C_4Ph_2O_2(CBrPh)$ [165°]. The compound $C_4Ph_2HO_2(CH_2Ph)$ is converted by potash into $CO_2H.C_2Ph_2.CH(OH).CH_2Ph$ [174°], and by an alcoholic solution of $NEtH_2$ into $CO(NHEt).C_2Ph_2.CH(OH).CH_2Ph$ [196°]. The compound $C_4Ph_2O_2(CHPh)$ is converted by KOH into $C_4Ph_2O_2(OH).CH_2Ph$ [185°], and in benzene solution by HNO_2 into $C_4Ph_2O_2(OH).CH(NO_2)Ph$ [125°] (which yields an acetyl derivative [166°]), and the compound $C_4Ph_2O_2(NO_2).CH(NO_2)Ph$ [146°], which is converted by boiling alcohol into $C_4Ph_2O_2{:}C(NO_2)Ph$ [177°], a body that may be reduced by HI and P to iso-benzyl-diphenyl-maleïde [118°]. Benzyl-di-phenyl-maleïde is converted by alcoholic NH_3 at 180° into

$\left.\begin{array}{l}\mathrm{CPh.CH(CH_2Ph)}\\ \mathrm{CPh.CO}\end{array}\right\rangle\mathrm{NH}$ [170°], which yields a nitrosamine [136°].

PHENYL-MALIC ACID *v.* OXY-PHENYL-SUCCINIC ACID.

PHENYL-MALONAMIC ACID *v.* MALONIC ACID.

DI-PHENYL-MALONIC ACID. *Ethyl ether of the nitrile* $CPh_2(CN).CO_2Et$. [59°]. Formed from $CPh_2Cl.CO_2Et$ and $HgCy_2$ at 125° (Bickel, *B.* 22, 1537). Yellowish tables.

Reference.—DI-NITRO-PHENYL-MALONIC ETHER.

PHENYL-MANDELIC ACID *v. Phenyl derivative* of MANDELIC ACID.

PHENYL-MELAMINE *v.* vol. ii. p. 322.

PHENYL MERCAPTAN C_6H_5SH. *Thiophenol. Phenyl-sulphydrate.* Mol. w. 110. (168°) (L.); (172°) (F. a. C.). S.G. ^{24} 1·078.

Formation.—1. A product of the dry distillation of sodium benzene sulphonate (Kekulé, *Z.* 1867 194; Stenhouse, *A.* 149, 248; *Pr.* 17, 62). 2. Together with Ph_2S and diphenylene sulphide by heating benzene with S and $AlCl_3$ at 75° (Friedel a. Crafts, *C. R.* 86, 884; *A. Ch.* [6] 14, 437).—3. By distilling phenol (10 mols.) with P_2S_5 (1 mol.), the yield being 6 p.c. of the phenol used (Kekulé, *Z.* [2] 3, 193, 306; Beckmann, *J. pr.* [2] 17, 456).—4. From Ph_2S_2 and K_2S in alcohol (Otto a. Rössing, *B.* 19, 3129).—5. By distilling $C_6H_5.SO_2Na$ with NaSH (Stadler, *B.* 17, 2080).

Preparation.—Phenyl ethyl dithiocarbonate, or a mixture of diazobenzene chloride solution and potassium ethyl dithiocarbonate (xanthate) is boiled with alcoholic potash until the solution remains clear on addition of water. The alcohol is then distilled off and the residue dissolved in water, mixed with a little H_2SO_4 and zinc-dust (to prevent oxidation), and distilled with steam. The distillate is extracted with ether. The yield is 75 p.c. of the theoretical (Leuckart, *J. pr.* [2] 41, 187).

Properties.—Oil, v. sol. alcohol and ether. Smells like garlic. Attacks the skin. Conc. H_2SO_4 forms a violet solution, changing on warming through cherry-red to blue (Baumann, *H.* 5, 321; *cf.* Brunner, *B.* 4, 984).

Reactions.—1. Readily oxidised to Ph_2S_2.—2. CH_3CCl_3 and dilute (20 p.c.) NaOHAq form $CH_3.C(SPh)_3$, crystallising in white plates; v. sol. hot alcohol (Laves, *B.* 25, 353).—3. *Aceto-acetic ether* and dry hydrochloric acid form $CH_3.C(SPh)_2.CH_2.CO_2Et$ [58°], crystallising from alcohol in plates. Not attacked by boiling HClAq, but decomposed by alkalis into alcohol, PhSH, and $CH_3.C(SPh){:}CH.CO_2H$ [177°] (Escales a. Baumann, *B.* 19, 1790).—4. $NH_2.COCl$ forms $NH_2.CO.NH.CO.SPh$ [218°] (Gattermann, *A.* 244, 43).—5. *Acetone* and HCl in the cold give $Me_2C(SPh)_2$ [56°] (Baumann, *B.* 19, 2804), which is oxidised by $KMnO_4$ and H_2SO_4 to $Me_2C(SO_2Ph)_2$ [97°]. — 6. *Chloro-acetone* reacts on PhSNa in ether, forming acetonyl-phenyl-sulphide $PhS.CH_2.CO.CH_3$ [35°] (269°) S.G. $_{x}$ 1·244 (Delisle, *A.* 260, 252). This body crystallises in prisms, sl. sol. hot water, v. sol. alcohol; combines with $KHSO_3$, yields a phenyl-hydrazide [82·5°], and is converted by oxidation into $Ph.SO_2.CH_2.CO.CH_3$ [57°]. Acetonyl-phenyl sulphide may be converted by successive treatment with HCy, alcoholic hydrochloric acid, and alcoholic potash into the acid $PhS.CH_2.CMe(OH).CO_2H$ [97°], which yields CaA'_2 aq, BaA'_2 aq, and AgA′, and is oxidised by $KMnO_4$ to $Ph.SO_2.CH_2.CMe(OH).CO_2H$ [121°].—7. *Chloral* forms $CCl_3.CH(OH)(SPh)$ [53°], decomposed by heat into its components (Baumann, *B.* 18, 886).—8. Combines with *pyruvic acid*, forming $CH_3.C(OH)(SPh).CO_2H$ [87°], but in presence of gaseous HCl it forms the 'mercaptol' $CH_3.C(SPh)_2.CO_2H$ [117°] which is not attacked by boiling HClAq or alcoholic potash.—9. *Phenyl-glyoxylic acid* forms $C_6H_5.C(OH)(SPh).CO_2H$ converted by HCl gas into $C_6H_5.C(SPh)_2.CO_2H$ [143°] (Escales a. Baumann, *B.* 19, 1789).—10. *β-Acetyl-propionic acid* does not combine directly, but in presence of hydrochloric acid it forms $CH_3.C(SPh)_2.CH_2.CH_2.CO_2H$ [69°], which is not attacked by alkalis, but is decomposed by dilute acids into PhSH and acetyl-propionic acid (E. a. B.).—11. $CH_3.CO.CH_2SPh$ forms $CH_3.C(SPh)_2.CH_2.SPh$ [55°], crystallising in cubes; v. sol. alcohol, insol. water; converted by oxidation in $CH_3.C(SPh)(SO_2Ph).CH_2.SO_2Ph$ [157°], crystallising in needles, sl. sol. cold alcohol, split up by alkalis into $Ph.SO_2.CH_3$, PhSH, and $Ph.SO_2H$ (Autenrieth, *B.* 24, 170).—12. $CBr_2(SO_2Et)_2$ and NaOHAq form $PhS.CH(SO_2Et)_2$ [86°], crystallising in tables; v. sl. sol. hot water, v. sol. alkalis; converted by alcoholic NaOH and MeI into $PhS.CMe(SO_2Et)_2$ [113°], crystallising in white needles; m. sol. hot alcohol (Fromm, *A.* 253, 166; Laves, *B.* 25, 361). — 13. NaSPh reacts with isobutylene bromide, forming NaBr, Ph_2S_2, and isobutylene (Otto, *B.* 23, 1052).

Salts.—NaSPh. When Na is dissolved in an ethereal solution of PhSH containing phenol, a pp. of NaSPh is got while NaOPh remains in solution.—$Hg(SPh)_2$: colourless needles (from alcohol).—ClHgSPh: plates.—$Pb(SPh)_2$: yellow crystalline pp., split up on distillation into PbS and Ph_2S.—$Cu(SPh)_2$: pale-yellow powder.—AgSPh: pale-yellow crystalline pp.

Methyl ether PhSMe. (188°). Formed from $Pb(SPh)_2$ and MeI (Obermeyer, *B.* 20, 2926).

Ethyl ether PhSEt. (204°) at 744 mm. Formed from NaSPh and EtI at 120° (Beckmann, *J. pr.* [2] 17, 457), and by the action of PhSH on PhN_2Cl (Stadler, *B.* 17, 2078). Liquid with unpleasant smell.

Allyl ether v. PHENYL ALLYL SULPHIDE.

Acetyl derivative PhSAc. (229°). Formed from phenyl mercaptan and AcCl (Michler, *A.* 176, 177). Oil.

References. — AMIDO-, BROMO-, CHLORO-, CHLORO-NITRO-, NITRO-, and OXY- PHENYL-MERCAPTAN.

PHENYL-MERCAPTURIC ACID $C_{11}H_{13}NSO_3$ *i.e.* $NHAc.CMe(SPh).CO_2H$. [143°]. Formed by reducing bromo-phenyl-mercapturic acid with sodium-amalgam (Baumann, *B.* 15, 1732; 18, 258; *H.* 5, 335; 8, 190). Tetrahedra, m. sol. alcohol. Lævorotatory in alcoholic solution. Solutions of its salts are dextrorotatory. Decomposed by dilute H_2SO_4 into HOAc and phenyl-cysteïn.—BaA'_2 3aq: needles.

References.—Bromo- and Chloro- Phenyl-mercapturic acid.

PHENYL-MESITYL-CARBINOL *v.* Phenyl-tri-methyl-phenyl-carbinol.

PHENYL-MESITYL-CARBINOL CARBOXYLIC ANHYDRIDE *v.* Tri-methyl-phenyl-phthalide.

PHENYL MESITYL KETONE *v.* Phenyl tri-methyl-phenyl ketone.

PHENYL-METHACRYLIC ACID *v.* Phenyl-crotonic acid.

PHENYL-METHACRYLIC ALDEHYDE CHPh:CMe.COH. (150° at 100 mm.). Formed by adding NaOHAq to a mixture of benzoic aldehyde and propionic aldehyde (Miller a. Kinkelin, *B.* 19, 525). Oil. Reduces ammoniacal $AgNO_3$. Combines with bisulphite. Yields a phenyl-hydrazide [137°].

PHENYL-METHANE *v.* Toluene.

Di-phenyl-methane $C_{13}H_{12}$ *i.e.* CH_2Ph_2. Mol. w. 168. [25°]. (c. 263°).

Formation.—1. Together with $C_6H_4(CH_2Ph)_2$, by boiling benzyl chloride with benzene and zinc-dust (Zincke, *B.* 4, 298; *C. J.* 24, 508, 688). 2. By the action of H_2SO_4 and HOAc on a mixture of benzene and benzyl alcohol (Meyer a. Wurster, *B.* 6, 963).—3. By heating benzophenone with zinc-dust (Staedel, *B.* 6, 1401; 7, 1480; *cf.* Barbier, *C. R.* 79, 812), or by reducing it with HI and P (Graebe, *B.* 7, 1624), or Zn and H_2SO_4 (Zincke, *B.* 10, 1473).—4. From benzene, CH_2Cl_2, and $AlCl_3$ (Friedel a. Crafts, *Bl.* [2] 41, 324; *A. Ch.* [6] 11, 264).—5. From $CH_2(OMe)_2$, benzene, HOAc, and H_2SO_4 (Baeyer, *B.* 6, 221).—6. By distilling barium di-phenyl-acetate with soda-lime (Jena, *A.* 155, 86).

Preparation.—By adding $AlCl_3$ (35 g.) to a mixture of benzyl chloride (100 g.) and benzene (500 g.) (Friedel a. Crafts, *A. Ch.* [6] 1, 478; *Bl.* [2] 33, 337).

Properties.—Prisms, v. sol. alcohol and ether, smelling like oranges. According to Reissert (*B.* 23, 2242) it melts at 23°. Oxidised by chromic acid mixture to benzophenone. Yields diphenylene-methane when passed through a red-hot tube (Graebe, *B.* 7, 1623). Prolonged treatment with Cl in presence of I forms CCl_4 and C_6Cl_6 (Ruoff, *B.* 9, 1048).

Tri-phenyl-methane $C_{19}H_{16}$ *i.e.* $CHPh_3$. [92°]. (330°) (Schwarz); (355°) (K. a. F.).

Formation.—1. By heating $PhCHCl_2$ with $HgPh_2$ at 150° (Kekulé a. Franchimont, *B.* 5, 907).—2. By heating $Ph_2CH(OH)$ with benzene and P_2O_5 at 135° (Hemilian, *B.* 7, 1203).—3. By heating (β)-benzpinacolin $C_{26}H_{20}O$ with soda-lime at 300° (Thörner a. Zincke, *B.* 9, 65).—4. Together with a little CH_2Ph_2 by adding $AlCl_3$ to a mixture of chloroform and benzene (Friedel a. Crafts, *J. pr.* [2] 16, 233; *A. Ch.* [6] 1, 496). 5. With other products, by the action of $AlCl_3$ on benzene mixed with CH_2Cl_2, with CCl_4, with $PhCCl_3$, and with CPhHBr.CPhHBr (Magatti, *B.* 12, 1468; Schwarz, *B.* 14, 1526; Anschütz, *A.* 235, 208).—6. By heating benzoic aldehyde (100 g.) with benzene (147 g.) and $ZnCl_2$ (100 g.) at 260° for 7 hours (Griepentrog, *B.* 19, 1876; *A.* 242, 329).

Preparation.—$AlCl_3$ (500 g.) is slowly added to a mixture of benzene (1400 g.) and chloroform (400 g.). The mixture is finally heated on the water-bath, water is carefully added, and the oil dried and fractionally distilled. It is finally purified by conversion into the compound with benzene (Allen a. Kölliker, *A.* 227, 108; *cf.* Fischer, *A.* 194, 252; Schwarz, *B.* 14, 1516). If the benzene contains toluene the product will contain a homologue (Hanriot, *Bl.* [3] 1, 773).

Properties.—Plates (from alcohol), v. sol. benzene, ether, and $CHCl_3$, m. sol. cold alcohol. Crystallises from benzene in efflorescent rhombohedra $CHPh_3C_6H_6$ [76°]. Oxidised by chromic acid to tri-phenyl-carbinol [159°]. $AlCl_3$ at 120° decomposes it, but below 80° it forms CH_2Ph_2 (Friedel a. Crafts, *C. R.* 100, 692). On exhaustive chlorination with $SbCl_5$ it yields CCl_4 and C_6Cl_6 (Merz a. Weith, *B.* 16, 2876). Na has no action at 300°, but K at 200° forms a red substance ($CKPh_3$). K at 250° forms a dark mass, whence HClAq liberates $C_{19}H_{14}$ [148·5°] (360°) (Hanriot a. Saint-Pierre, *C. R.* 108, 1119; *Bl.* [3] 1, 774). The potassium derivative $CKPh_3$ absorbs CO_2 at 200°, yielding $CPh_3.CO_2H$ [264°]. Benzyl chloride acting on $CKPh_3$ forms the compound $CPh_3.CH_2Ph$ [140°]. BzCl forms $C_{26}H_{18}O$ [172°] which may be reduced by HI and P to $C_{26}H_{20}$ [234°].

References. — Amido-, Bromo-, Chloro-, Methyl-amido-, Nitro-, Nitro-amido-, Oxy-amido-, and Oxy- Phenyl-methane.

DI-PHENYL-METHANE DI-*o*-CARBOXYLIC ACID $CH_2(C_6H_4.CO_2H)_2$. [255°]. Formed by reducing the lactone of $CH(OH)(C_6H_4.CO_2H)_2$ with HI and P (Graebe a. Juillard, *A.* 242, 253). Crystals (from alcohol). Yields anthraquinone on heating at 280°.—BaA″ 6aq. S. 4·7.

Methyl ether Me_2A''. [44°].

Isomeride *v.* Benzyl-isophthalic acid.

Di-phenyl-methane tricarboxylic acid $CO_2H.CH(C_6H_4.CO_2H)_2$. [220°]. S. ·095 at 25°. Got by heating the lactone of the oxyacid $CO_2H.C(OH)(C_6H_4.CO_2H)_2$ with HI and P at 170° (Graebe a. Juillard, *A.* 242, 235). Crystals (containing aq). At 270° it forms a red compound $C_{15}H_8O_4$ [261°].

Methyl ether Me_3A'''. [145°].

Tri-phenyl methane *o*-carboxylic acid $CHPh_2.C_6H_4.CO_2H$. [162°].

Formation.—1. By the action of NaOH an zinc-dust on di-phenyl-phthalide (Baeyer, *B.* 1 644; *A.* 202, 52).—2. By heating phenyl phthalide with benzene and $AlCl_3$ (Gresly, *A* 234, 242).—3. By saponifying the nitrile, which is obtained from $CHCl_2.C_6H_4.CN$, benzene, an $AlCl_3$ (Drory, *B.* 24, 2572).

Properties.—Needles (from alcohol), insol water. May be sublimed. Yields tri-phenyl methane when heated with $Ba(OH)_2$. CrO_3 i HOAc oxidises it to diphenyl-phthalide.

Nitrile $CHPh_2.C_6H_4.CN$. [89°].

Tri-phenyl-methane-*p*-carboxylic acid [162°]. Obtained by saponifying the nitrile which is obtained by Sandmeyer's reaction from *p*-amido-tri-phenyl-methane [84°] (Fischer a Fränkel, *A.* 241, 364; Otto a. Fischer, *B.* 24, 729). Needles, v. sol. alcohol and ether.—AgA'.

An isomeric acid melting above 360° was obained by Oppenheimer (*B.* 19, 2029) by oxidising he corresponding aldehyde with Ag_2O.

Tri-phenyl-methane dicarboxylic acid $CHPh_2.C_6H_3(CO_2H)_2$ [1:2:5]. [280°]. Formed by reduction of the lactone of tri-phenyl-carbinol dicarboxylic acid by zinc-dust and NaOH (Hemilian, *B.* 16, 2375). Needles (from HOAc). Conc. H_2SO_4 forms a greenish-yellow solution, which on heating changes through green, blue, and violet to purple.—BaA″ 4aq.—Ag_2A'': pp.

Tri-phenyl-methane dicarboxylic acid $CHPh_2.C_6H_3(CO_2H)_2$ [1:3:4]. [278°]. Formed by boiling di-phenyl-phthalide dicarboxylic acid with zinc-dust and NaOHAq (Hemilian, *B.* 19, 3068). Needles (from dilute alcohol). May be sublimed. Yields $CHPh_3$ when distilled with $Ba(OH)_2$. Re-oxidised by alkaline $KMnO_4$ to di-phenyl-phthalide dicarboxylic acid.—CaA″ 2aq: needles.—Ag_2A'': curdy pp.

Reference.—OXY-DI-PHENYL-METHANE CARBOXYLIC ACID.

DIPHENYL-METHANE DISULPHONIC ACID $C_{13}H_{10}(SO_3H)_2$. [59°]. Got by sulphonation (Doer, *B.* 5, 796). Deliquescent plates.—K_2A'' aq: prisms (from dilute alcohol).—BaA″.—CuA″: green plates.

Tri-phenyl-methane trisulphonic acid $C_{19}H_{13}(SO_3H)_3$. Formed by warming $CHPh_3$ with fuming H_2SO_4 (Kekulé a. Franchimont, *B.* 5, 908; Hemilian, *B.* 7, 1205).—$Ba_3A'''_2$ 8aq: needles, ppd. by adding alcohol to its aqueous solution.

DI-PHENYL-METHAZINE $C_{11}H_{12}O_2$ *i.e.*

$CHPh<\begin{matrix}N\\N\end{matrix}>CHPh$

[93°]. Formed by shaking a dilute solution of hydrazine with benzoic aldehyde (Curtius, *J. pr.* [2] 39, 44). Light-yellow prisms, v. sl. sol. hot water, v. sol. hot alcohol. Decomposed by boiling into CHPh:CHPh and nitrogen, and by boiling dilute acids into benzoic aldehyde and hydrazine. Reduced in alcoholic solution by sodium-amalgam to di-benzyl-hydrazine, and by excess of Na to benzylamine.

PHENYL-METHENYL-AMIDINE *v.* BENZAMIDINE.

Diphenyl-methenyl-diamine is described as DI-PHENYL-FORMAMIDINE.

PHENYL-METHENYL-AZIDINE $C_7H_9N_3$ *i.e.* $NH_2.CH:N_2HPh$. [225°]. Formed from phenyl-hydrazine and HCy (Fischer, *B.* 22, 1934). Insol. water, v. sol. hot alcohol. The nitrate and hydrochloride are crystalline.

PHENYL METHENYL DI-ETHYL TRISULPHONE $C_6H_5.SO_2.CH(SO_2.C_2H_5)_2$. [166°]. S. 2 at 15°. Formed by oxidising $PhS.CH(SO_2Et)_2$ with alkaline $KMnO_4$ (Fromm, *A.* 253, 167; Laves, *B.* 25, 362). Snow-white needles, v. sol. alkalis.—KA′: prisms.—BaA'_2: tables.

TRI-PHENYL METHENYL TRIKETONE *v.* TRI-BENZOYL-METHANE.

TRI-PHENYL METHENYL TRISULPHONE $CH(SO_2Ph)_3$. [215°]. Formed by oxidising $PhS.CH(SO_2Ph)_2$ with alkaline $KMnO_4$ (Laves, *B.* 25, 348). Tables, v. sol. alcohol, insol. ether, m. sol. water.—KA′: tablets.—BaA'_2.—AgA′.

DI-PHENYL-DI-METHYL-ACETYLENE TETRAKETONE *v.* DI-BENZOYL-DI-ACETYL-ETHANE.

PHENYL-METHYL-ACRIDINE $C_{20}H_{15}N$ *i.e.*

$C_6H_4<\begin{matrix}\text{CPh.C.CH:CMe}\\ \text{N — C.CH:CH}\end{matrix}$

[136°]. Formed by heating phenyl-*p*-toluidine with benzoic acid and $ZnCl_2$ at 260° (Bonna, *A.* 289, 62). Needles, sl. sol. water. Its alcoholic solution shows greenish-blue fluorescence. Yields phenyl-acridine carboxylic acid [253°] on oxidation.—B′HCl: yellow needles.—B′HI.—$B'_2H_2SO_4$.—$B'C_6H_3N_3O_7$. Red needles.

Phenyl-methyl-acridine dihydride

$C_6H_4<\begin{matrix}CHPh\\NMe\end{matrix}>C_6H_4$

[104°]. Formed by the action of MeI on phenyl-acridine dihydride; or by reduction of the methylo-chloride of phenyl-acridine with zinc-dust (Bernthsen a. Bender, *B.* 16, 1816). White needles or prisms. On oxidation with nitrous acid it gives the methylo-hydroxide of phenyl-acridine.

PHENYL-METHYL-ALLYL-PYRROLE

$\begin{matrix}\text{CH:CMe}\\ \text{CH:CPh}\end{matrix}>NC_3H_5$

[52°]. (278°). Formed by heating the carboxylic acid [158°] (Lederer a. Paal, *B.* 18, 2595). Large colourless plates. Blue fluorescence. Extremely sol. all ordinary solvents.

PHENYL-METHYL-ALLYL-PYRROLE CARBOXYLIC ACID

$\begin{matrix}\text{CH:CPh}\\ \text{CO}_2\text{H.C}=\text{CMe}\end{matrix}>NC_3H_5$

[158°]. Obtained by saponification of its ether, which is formed by the action of allylamine upon acetophenone-acetoacetic ether (Lederer a. Paal, *B.* 18, 2594). Short glistening prisms. V. sol. alcohol, ether, benzene, and acetic acid.

PHENYL-METHYL-AMIDO-ACETIC ACID $C_9H_{11}NO_2$ *i.e.* $CH_2(NPhMe).CO_2H$. *Phenyl-methyl-glycocoll.* Formed by heating chloro-acetic ether with dimethylaniline and saponifying the product by boiling HClAq (Silberstein, *B.* 17, 2661). Liquid.—HA′HCl: prisms.

Amide. $CH_2(NPhMe).CO.NH_2$. [168°]. Formed by heating $CH_2Cl.CONH_2$ with $NPhMe_2$ or NPhMeH. Crystals, sol. hot water. Its hydrochloride forms easily soluble prisms.

Methylo-chloride $CH_2(NPhMe_2Cl).CO_2H$. Formed by warming chloro-acetic acid with $NPhMe_2$ in ether (Zimmermann, *B.* 12, 2206). Needles. Moist Ag_2O forms an hydroxide.

Amide of the methylo-chloride $CH_2(NPhMe_2Cl).CO.NH_2$. Formed by heating chloro-acetamide with dimethylaniline in alcohol (S.). Crystals, decomposed by heat into MeCl and $CH_2(NPhMe).CO.NH_2$.

PHENYL-METHYL-ω-AMIDO-ACETOPHENONE $C_6H_5.CO.CH_2.NPhMe$. *Phenacyl-methyl-aniline.* [120°]. Formed by the action of NPhMeH or $NPhMe_2$ on ω-bromo-acetophenone (Staedel a. Siepermann, *B.* 18, 842; 14, 983; 21, 2196). Prisms (from alcohol). A solution of its hydrochloride gives a red pp. with dilute HNO_3 (Weller, *B.* 16, 27). $ZnCl_2$ forms $C_{15}H_{13}N$ [102°].—$B'_2H_2PtCl_6$: tables.—B′MeI. Crystals.—B′MeOH. Strongly alkaline.

PHENYL-METHYL-AMIDO-BENZENE PHOSPHINIC ACID $NPhMe.C_6H_4.P(OH)_2$. [150·5°]. Formed by the action of NaOHAq on the oily chloride $NPhMe.C_6H_4.PCl_2$, which is formed by the action of $AlCl_3$ on a mixture of NPh_2Me and PCl_3 (Michaelis, *A.* 260, 37). Small needles (from water) or plates (from alcohol).—NaHA″ 2aq. [265°]. Plates, v. e. sol. water.

PHENYL-METHYL-AMIDO-BENZOIC ACID $C_{14}H_{13}NO_2$ *i.e.* $C_6H_4(NPhMe).CO_2H$. [184°]. Formed from NPh_2Me and $COCl_2$ (Michler a. Sarauw, *B.* 14, 2180). Plates.—BaA'_2: pearly plates.—AgA': white pp.

PHENYL-METHYL-AMIDO-ETHANE SULPHONIC ACID $NPhMe.C_2H_4.SO_3H$. Formed from $CH_2Cl.CH_2.SO_3H$ and methylaniline at 160° (James, *J. pr.* [2] 31, 417). Silky crystals (from alcohol).

PHENYL - METHYL - AMIDO - ETHYL - PHTHALIMIDE $C_8H_4O_2:N.C_2H_4.NPhMe$. [105°]. Formed from bromo-ethyl-phthalimide and methyl-aniline at 165° (Newman, *B.* 24, 2199). Greenish-yellow four-sided tables, v. c. sol. C_6H_6.

PHENYL - METHYL - AMIDO-METHENYL-AMIDO-PHENOL $C_{14}H_{12}N_2O$ *i.e.* $C_6H_4{<}\substack{N\\O}{>}C.NPhMe$. (above 360°). Formed from  $C_6H_4{<}\substack{N\\O}{>}C.SH$ and methyl-aniline (Kalckhoff, *B.* 16, 1825). Syrup, with blue fluorescence.—$B'_2H_2PtCl_6$: prisms.

PHENYL - METHYL - AMIDO-DI-METHYL-PYRROLE $C_{13}H_{16}N_2$ *i.e.* $NPhMe.N{<}\substack{CMe:CH\\CMe:CH}$. [41°]. (310°). Formed by heating its dicarboxylic acid at 231° (Knorr, *A.* 236, 310). Crystalline mass, v. sol. alcohol. Volatile with steam.

Phenyl-methyl-amido-di-methyl-pyrrole dicarboxylic acid $C_{15}H_{16}N_2O_4$. Formed by saponification of its oily ether, which is formed from diacetyl-succinic ether and phenyl-methyl-hydrazine (K.). Prisms, decomposing at 231°.—AgA': flocculent pp.

PHENYL - METHYL - *p* - AMIDO - PHENOL. *Methyl derivative* $NPhMe.C_6H_4.OMe$. (313°). Formed from phenyl-*p*-amido-phenol, KOH, and MeI (Philip a. Calm, *B.* 17, 2433). Oil, insol. NaOHAq.

PHENYL - TETRA - METHYL - TRI - AMIDO-DI-PHENYL-NAPHTHYL-CARBINOL $C_{33}H_{33}N_3O$ *i.e.* $NPhH.C_{10}H_6.C(OH)(C_6H_4.NMe_2)_2$. [95°]. *Base of Victoria Blue B.* Formed by heating tetra-methyl-di-amido-benzophenone (10 pts.) with phenyl-(*a*)-naphthylamine (9 pts.), and $POCl_3$ (7 pts.) at 110° (Nathansohn a. Müller, *B.* 22, 1890). The base is set free by NaOHAq. Brick-red powder, v. sol. alcohol and benzene.—$(C_{33}H_{32}N_3Cl)_2PtCl_4$: violet needles.—$C_{33}H_{31}N_3C_6H_2(NO_2)_3OH$: dark-blue pp.

Phenyl - penta - methyl-tri-amido-di-phenyl-naphthyl-carbinol $C_{34}H_{35}N_3O$ *i.e.* $NPhMe.C_{10}H_6.C(OH)(C_6H_4.NMe_2)_2$. [77°]. The chloride $C_{34}H_{34}N_3Cl$, '*Victoria Blue* 4 *R*,' formed by the action of methyl-phenyl-(*a*)-naphthylamine on $CO(C_6H_4NMe_2)_2$ in presence of $POCl_3$ is v. sol. hot water (Nathansohn a. Müller, *B.* 22, 1892). The carbinol is a brick-red pp., v. sol. alcohol. It forms $(C_{34}H_{34}N_3Cl)_2PtCl_4$ and $C_{34}H_{33}N_3C_6H_2(NO_2)_3OH$ crystallising in very small dark-blue needles.

PHENYL - TETRA - METHYL - TRI-AMIDO-DI-PHENYL-NAPHTHYL-METHANE $C_{33}H_{33}N_3$ *i.e.* $NHPh.C_{10}H_6.CH(C_6H_4.NMe_2)_2$. [125°]. Formed by reducing the carbinol (*v. supra*) (Nathansohn a. Müller, *B.* 22, 1891). Flocculent pp., v. sol. hot alcohol. Yields $B'''_2H_2PtCl_6$ and $B'''C_6H_3N_3O_7$, both being crystalline.

Phenyl-penta-methyl-tri-amido-di-phenyl-naphthyl-methane $C_{34}H_{35}N_3$ *i.e.* $NPhMe.C_{10}H_6.CH(C_6H_4NMe_2)_2$. [87°]. Formed by reducing the carbinol (N. a. M.). Amorphous. Yields crystalline $B'''_2H_2PtCl_6$ and $B'''C_6H_3N_3O_7$.

PHENYL DI - METHYL - AMIDO - TOLYL KETONE $C_6H_5.CO.C_6H_3Me.NMe_2$. [67°]. (350°-360°). Formed from benzoic acid, di-methyl-*o*-toluidine, and P_2O_5 (O. Fischer, *A.* 206, 91).

PHENYL-TETRA - METHYL-DI-AMIDO-DI-TOLYL-METHANE $C_{23}H_{30}N_2$ *i.e.* $CHPh(C_6H_3Me.NMe_2)_2$. [109°]. Formed by heating di-methyl-*m*-toluidine with benzoic aldehyde and $ZnCl_2$ (Fischer, *B.* 13, 807). Prisms.—$B''H_2PtCl_6$ 2aq: small yellow crystals.

PHENYL-METHYL-AMINE *v.* METHYL-ANILINE.

Phenyl-di-methyl-amine *v.* DI-METHYL-ANILINE.

Di-phenyl-methyl-amine *v.* METHYL-DI-PHENYL-AMINE.

Tri-phenyl-methyl-amine *v.* TRI-PHENYL CARBINYLAMINE.

PHENYL-METHYL-ANTHRACENE $C_{21}H_{16}$ *i.e.* $C_6H_3Me{<}\substack{CPh\\CH}{>}C_6H_4$. [119°]. Obtained by distilling phenyl-methyl-anthranol with zinc dust (Hemilian, *B.* 16, 2367). Yellow pointed crystals. Dissolves in alcohol and ether, with a strong greenish-blue fluorescence. By CrO_3 in acetic acid it is oxidised to phenyl-methyl-oxanthranol.

PHENYL-METHYL-ANTHRANOL $C_{21}H_{16}O$ *i.e.*  $C_6H_3Me{<}\substack{CPh\\C(OH)}{>}C_6H_4$. [157°]. Obtained by heating di-phenyl-tolyl-methane carboxylic acid with H_2SO_4 (Hemilian, *B.* 16, 2365). Yellow glistening tables. Sol. ether, boiling alcohol and acetic acid, insol. cold alkalis, but dissolves on boiling to a yellow solution. On oxidation it gives phenyl-methyl-oxanthranol.

PHENYL-DI-METHYL-ARSINE *v.* vol. i. p. 320.

DI - PHENYL - DI - METHYL - AZIMETHYLENE $N_2(CMePh)_2$. [121°]. Formed by the action of acetophenone on hydrazine hydrate or on $CPhMe:N.NH_2$ (Curtius, *J. pr.* [2] 44, 542).

PHENYL-METHYL-BIAZOLE DIHYDRIDE  $O{<}\substack{CH_2.NPh\\CMe:N}$. [140°]. Formed by the action of tin and HCl on  $O{<}\substack{CCl_2.NPh\\CMe:N}$ [122°], which is made by the action of $COCl_2$ on acetyl-phenyl-hydrazine (Freund a. Kuh, *B.* 23, 2838). Yellowish plates.

PHENYL-METHYL-TRIAZOLE $C_9H_9N_3$ *i.e.*  $\substack{N.NPh\\CMe.N}{>}CH$. Formed by heating its carboxylic acid to 180° (Bladin, *B.* 19, 2602). Oil. $B'_2H_2PtCl_6$ aq. [124°]. Lemon-yellow tables.

PHENYL-METHYL-TRIAZOLE CARBOXYLIC ACID  $\substack{N.NPh\\CMe.N}{>}C.CO_2H$. [177°]. Formed by saponifying its nitrile, which is got by the action of Ac_2O on phenyl-hydrazine dicyanide and also by gently warming phenyl-hydrazine dicyanide with an alcoholic solution of pyruvic acid (Bladin, *B.* 18, 1544; 19, 2598; 22, 1749; 25, 185).

Salts. — CuA'_2 1½aq. — PbA'_2 2½aq. — AgA' 1½aq.—$HA'HCl$: tables (from HClAq).

Ethyl ether EtA'. Oil.

Nitrile. [109°]. Prisms.

Amide $C_2N_3PhMe.CO.NH_2$. [170°]. Prisms, m. sol. water and alcohol.

Amidoxim $C_2N_3PhMe.C(NH_2):NOH$. [210°]. Formed from the nitrile and hydroxylamine in alcohol. Plates (from alcohol), v. sl. sol. water. $FeCl_3$ colours its alcoholic solution deep red. Yields B'HCl and $B'_2H_2PtCl_6$ [201°]. Ac_2O forms $C_2N_3PhMe.C(NH_2):NOAc$ [148°] and $C_2N_3PhMe.C{<}\begin{matrix}N.O\\N\end{matrix}{>}CMe$ [105·5°]. BzCl forms $C_2N_3PhMe.C(NH_2):NOBz$ [18[illegible]5°] converted by heat into $C_2N_3PhMe.C{<}\begin{matrix}N.O\\N\end{matrix}{>}CPh$ [167°].

DI-PHENYL-DI-METHYL-TETRAZONE NPhMe.N:N.NPhMe. [137°]. Formed by oxidising phenyl-methyl-hydrazine (Fischer, *A.* 190, 152; Tafel, *B.* 18, 1744). Monoclinic plates. With I in $CHCl_3$ it forms $C_{14}H_{16}N_4I_4$, a black crystalline pp.

DI-PHENYL-DI-METHYL-DI-TRIAZYL $\begin{matrix}N.NPh\\CMe.N\end{matrix}{>}C.C{<}\begin{matrix}NPh.N\\N-CMe\end{matrix}$ [223°]. Formed by heating the cyanide of phenyl-hydrazine with Ac_2O (Bladin, *B.* 21, 3063). Prisms (from alcohol).—$B''H_2Cl_2$.—$B''H_2PtCl_6$ ½aq. Plates.

DI-PHENYL-METHYL-BENZAMIDINE $C_6H_5.C(NMe).NPh_2$. Formed by heating di-phenyl-benzamidine with MeI at 130° (Bernthsen, *A.* 192, 17). Syrup.—$B'_2H_2PtCl_6$: yellow pp.

PHENYL *p*-METHYL-BENZYL KETONE $C_6H_5.CO.CH_2.C_6H_4Me$. [94°]. Formed from *p*-tolyl-acetic chloride, benzene, and $AlCl_3$ (Strassmann, *B.* 22, 1231). Yields an oxim [109°].

PHENYL-METHYL-BENZYL-UREA $NHPh.CO.NH.CH_2C_6H_4Me$. [131°]. Formed from *m*-methyl-benzylamine and phenyl cyanate (Brömme, *B.* 21, 2700).

TRI-PHENYL-METHYL-BROMIDE *v.* Bromo-tri-phenyl-methane.

PHENYL-METHYL-CARBAMIC ACID.

Ethyl ether NPhMe.CO.OEt. (244°). Formed from methylaniline and $Cl.CO_2Et$ (Gebhardt, *B.* 17, 3042). Yellow oil.

Chloride NPhMe.COCl. [88°]. (280°). Got by passing $COCl_2$ into a solution of methylaniline in benzene (Michler a. Zimmermann, *B.* 12, 1165). Tables (from alcohol), insol. water. Reacts with toluene and aluminium chloride, forming $NPhMe.CO.C_6H_4Me$ [70°] while $AlCl_3$ and *o*-, *m*-, and *p*- xylene give rise to the compounds $NPhMe.CO.C_6H_3Me_2$ melting at 78°, 54°, and 74° respectively (Lellmann, *B.* 24, 2114).

Phenyl ether $NPhMe.CO.OC_6H_5$. [58°]. Formed from the chloride and KOPh in alcohol (Lellmann a. Benz, *A.* 24, 2108). Large crystals.

Nitro-phenyl ethers $C_6H_4(NO_2)A'$. The *o*-, *m*-, and *p*- nitro-phenyl ethers melt at 110°, 105°, and 70° respectively. They yield on reduction the corresponding amido-phenyl ethers melting at 103°, 94°, and 104° respectively.

p-Tolyl ether C_6H_4MeA'. [62°].

PHENYL-METHYL-SEMI-CARBAZIDE $NPhMe.NH.CO.NH_2$. [133°]. Formed from phenyl-methyl-hydrazine hydrochloride and potassium cyanate (Fischer, *A.* 190, 164). Crystalline mass, m. sol. hot water. Yields a nitrosamine $NPhMe.N(NO).CO.NH_2$ [77°].

Phenyl-di-methyl-semi-carbazide $NMe_2.NH.CO.NHPh$. [108°]. Formed from phenyl-cyanate and di-methyl-hydrazine (Renouf, *B.* 18, 2172). Pyramids. Decomposed by HCl into the parent substances.

Di-phenyl-di-methyl-carbazide $CS(NH.NPhMe)_2$. [c. 168°]. Got by heating phenyl-methyl-hydrazine with CS_2 (Stahel, *A.* 258, 250).

PHENYL-METHYL-CYANIDE *v. Nitrile* of Phenyl-acetic acid.

Di-phenyl-methyl-cyanide *v. Nitrile* of Di-phenyl-acetic acid.

Di-phenyl-methyl dicyanide $C_{16}H_{13}N_3$ *i.e.* $N{<}\begin{matrix}CMe.N\\CPh:N\end{matrix}{>}CPh$. [110°]. (227° at 15 mm.). Formed from benzonitrile, AcCl, and $AlCl_3$ (Krafft a. Hansen, *B.* 22, 803; 23, 2382). Needles, sol. alcohol and ligroïn. Decomposed by diluted H_2SO_4 into benzoic acid, acetic acid, and NH_3. Oxidised by alkaline $KMnO_4$ to $C_3N_3Ph_2.CO_2H$ [c. 192°] which on heating yields $C_3N_3Ph_2H$ [75°] (205° at 9 mm.).

Salts.—B'HCl: needles.—$B'_2H_2PtCl_6$.

DI-PHENYL-METHYLENE-*p*-AMIDO-BENZOIC ACID $CPh_2:N.C_6H_4.CO_2H$. [240°]. Formed from Ph_2CCl_2 and *p*-amido-benzoic acid (Hantzsch a. Krafft, *B.* 24, 3522). Short prisms.

PHENYL-METHYLENE-AMINE $CH_2:NPh$ or $CH_2{<}\begin{matrix}NPh\\NPh\end{matrix}{>}CH_2$? [140°]. Formed by adding aniline to a solution of formic aldehyde (Wellington a. Tollens, *B.* 18, 3309). Formed also from trioxymethylene and aniline (Kolotoff, *J.* 1885, 777). Long slender needles. Decomposed by water at 100° into trioxymethylene and aniline.

Phenyl-trimethylene-diamine $NHPh.C_3H_6.NH_2$. (282° cor.). S.G. $\frac{0}{0}$ 1·0356. A product of the action of Na on an alcoholic solution of phenyl-pyrazole (Balbiano, *G.* 18, 354; 19, 688; *Rend. Accad. Linc.* [4] 4, ii. 44). Formed also by boiling phenyl-γ-amido-propyl-phthalimide with HClAq (Goldenring, *B.* 23, 1169). Oil. Sulphide of carbon forms $NHPh.C_3H_6.NH.CS.SNH_2Ph.C_3H_6NH_2$, crystallising from alcohol in white plates.—B''2HCl: tufts of needles, v. e. sol. water. When heated it gives off NH_3 and $NPh:C_3H_6$, which forms $(C_9H_{11}N)_2H_2PtCl_6$.—$C_9H_{11}N,2C_6H_3N_3O_7$. Greenish crystals, decomposing at 195°.—**Succinate** [100°].

Phenyl-di-trimethylene-triamine $NPh(CH_2.CH_2.CH_2.NH_2)_2$. Formed by heating its phthalyl derivative with HClAq at 240° (Goldenring, *B.* 23, 1170).—B'''3HCl.—$B'''_2 3H_2PtCl_6$.

Di-phthalyl derivative $NPh(CH_2.CH_2.CH_2.N:C_8H_4O_2)_2$ [145°]. Formed from γ-bromo-propyl-phthalimide and aniline.

Di-phenyl-methylene-amine $CPh_2:NH$. Formed by heating CPh_2Cl_2 with carbamic ether at 130° (Hantzsch a. Krafft, *B.* 24, 3517). Colourless liquid.—B'HCl: snow-white powder.

Di-phenyl-methylene-diamine $CH_2(NHPh)_2$. [49°]. Formed by mixing a large excess of an aqueous solution of aniline with formic aldehyde solution (Pratesi, *G.* 14, 351; *cf.* Lermontoff, *B.* 7, 1255). Four-sided tables, sol. alcohol. Its hydrochloride is unstable.—$B''H_2PtCl_6$.

Di-phenyl-trimethylene-diamine $CH_2(CH_2.NHPh)_2$. Formed from aniline and trimethylene bromide (Hanssen, *B.* 20, 781). Thick brown liquid.—$B''H_2SO_4$. [156°]. Needles.

Nitrosamine $CH_2(CH_2.NPh.NO)_2$. [87°].

DI-PHENYL-METHYLENE-ANILINE $NPh:CPh_2$. [109°]. (above 360°). Formed from CPh_2Cl_2 and aniline (Pauly, *A.* 187, 199). Yellow tables (from ether). Split up by HClAq into aniline and benzophenone.

TETRA-PHENYL-DI-METHYLENE-TETRAZONE $N_2(N:CPh_2)_2$. Formed by shaking a benzene solution of $NH_2.N:CPh_2$ with HgO (Curtius a. Rauterberg, *J. pr.* [2] 44, 200). Red needles. Decomposes readily into nitrogen and $CPh_2:N.N:CPh_2$. Gaseous HBr forms CPh_2HBr [88°].

DI-PHENYL-TRIMETHYLENE-DI-CARBAMIC ACID.

Ethyl ether $CH_2(CH_2.NPh.CO_2Et)_2$. [56°]. Formed from the chloride and NaOEt (Hanssen, *B.* 20, 783). Crystalline.

Chloride $CH_2(CH_2.NPh.COCl)_2$. [102°]. Formed from $CH_2(CH_2NPhH)_2$ and $COCl_2$ in benzene. Needles.

PHENYL-TRIMETHYLENE DICARBOXYLIC ACID $CHPh\Big<{CH.CO_2H \atop CH.CO_2H}$. [175°]. Got by saponifying its ether. Prisms, m. sol. water, v. sol. alcohol and ether (Buchner a. Dessauer, *B.* 21, 2646; 25, 1152). When heated *in vacuo* it yields an anhydride $C_{11}H_8O_3$ [134°].—NaHA″: needles.

Di-methyl ether Me_2A''. [63°].

Ethyl ether Et_2A'' (257° at 120 mm.). Formed by distilling $CO_2Et.CH\Big<{N.CHPh \atop N.CH.CO_2Et}$ *in vacuo*. Thick oil.

Phenyl-trimethylene-tri-carboxylic acid $C_3H_2Ph(CO_2H)_3$. [188°]. Got by saponifying its ether (B. a. D.). Crystals containing 4aq.

Methyl ether Me_3A'''. [47°]. (210° at 20 mm.). Formed from NaOMe, methyl malonate, and methyl di-bromo-phenyl-propionate.

PHENYL METHYLENE ETHYL DIKETONE $C_6H_5.CO.CH_2.CO.C_2H_5$. *Propionyl-acetophenone.* (277°). S.G. ^{15} 1·081. Formed from acetophenone, propionic ether, and NaOEt (Stylos, *B.* 20, 2181). Liquid.

DI-PHENYL-METHYLENE-HYDRAZINE $CPh_2:N.NH_2$. [98°]. (c. 227° at 55 mm.). *Hydrazide of benzophenone.* Formed by heating benzophenone (5 g.) with hydrazine hydrate (1·8 g.) and alcohol (1 g.) at 150° (Curtius a. Lauterberg, *J. pr.* [2] 44, 192). Prisms (from alcohol). Reduces alcoholic $AgNO_3$ forming a mirror. Reduces Fehling's solution on warming. Boiling dilute H_2SO_4 splits off hydrazine. Reacts readily with ketones.—B′HCl. [183°].

Acetyl derivative. [107°]. Prisms.

Benzoyl derivative. [116·5°]. Prisms.

Tetra-phenyl-di-methylene-hydrazine $CPh_2:N.N:CPh_2$. *Di-phenyl-ketazine.* [162°]. Formed by boiling $CPh_2:N.NH_2$ with iodine in alcohol. Yellow prisms, v. sl. sol. hot water, sol. alkalis. Decomposed by boiling dilute H_2SO_4 into benzophenone and $N_2H_4H_2SO_4$.

Phenyl-trimethylene-hydrazine $C_9H_{12}N_2$. [58°]. Got from phenyl-hydrazine and trimethylene bromide (Marckwald, *C. C.* 1888, 1410). Converted by trimethylene bromide on further heating into $(PhN_2)_2(C_3H_6)_3$ [226°].

DI-PHENYL METHYLENE DIKETONE $CH_2(CO.C_6H_5)_2$. *Benzoyl-acetophenone. Dibenzoyl-methane.* [81°]. (over 200°).

Formation.—1. By boiling di-benzoyl-acetic acid with water (Baeyer a. Perkin, jun.; *B.* 16, 2184; *C. J.* 47, 240).—2. By the action of malonyl chloride and $AlCl_3$ upon benzene (Auger, *A. Ch.* [6] 22, 348).

Preparation.—By adding dry sodium ethylate to a mixture of acetophenone and benzoic ether, the reaction taking place with spontaneous heating. The crystalline mass is extracted with cold water, finally with dilute NaOH, and from the solution of the sodium salt the ketone is precipitated by means of CO_2; the yield is c. 50 p.c. of the acetophenone used (Claisen, *B.* 20, 655).

Properties.—Trimetric plates, v. sol. alkalis. Yields products of substitution by treatment with NaOEt and alkyl iodides.

Reactions.—1. *Bromine* (1 mol.) in $CHCl_3$ forms Bz_2CHBr [93°], which on heating with HOAc and KOAc yields Bz_2CHOAc [94°], which on further bromination gives $Bz_2CBr.OAc$ [102°] which is split up by heat into Ph.CO.CO.CO.Ph and AcBr.—2. Excess of *bromine* (2 mols.) in $CHCl_3$ forms Bz_2CBr_2 [95°] whence HOAc and KOAc form di-phenyl triketone.—3. Amyl nitrite and alcoholic HCl give $Bz_2C:NOH$ [146°], converted by nitrous acid into the triketone (Neufville a. Pechmann, *B.* 22, 852; 23, 3376).—4. *Phenyl-hydrazine* forms tri-phenyl-pyrazole (Japp a. Klingemann, *B.* 22, 2886).

PHENYL METHYLENE METHYL DIKETONE *v.* BENZOYL-ACETONE.

PHENYL METHYLENE METHYL SULPHONE-KETONE $C_6H_5.SO_2.CH_2.CO.CH_3$. *Acetonyl phenyl sulphone.* [57°]. Formed by oxidising $PhS.CH_2Ac$ with $KMnO_4$ (Delisle, *A.* 260, 262). Formed also from chloro-acetone and $C_6H_5.SO_2Na$ (Otto, *B.* 19, 1642; 21, 1871; 23, 756; *J. pr.* [2] 36, 402). Plates, sol. water and alcohol. Yields a phenyl-hydrazide [129°] and an oxim [148°]. Ammonia yields the compound $NH:CMe.CH_2.SO_2Ph$ [111°]. Phenyl mercaptan yields $(PhS)_2CMe.CH_2SO_2Ph$ [104]. Potash yields phenyl methyl sulphone. Br forms a bromo-derivative [96°] and a di-bromo-derivative [114°].

PHENYL-METHYLENE-PHTHALIMIDINE $C_{15}H_{11}NO$ *i.e.* $C_6H_4\Big<{C(CH_2) \atop CO-\!-}\Big>NPh$. [100°]. Formed by heating acetophenone *o*-carboxylic anilide at 230° (Mertens, *B.* 19, 2372). Prisms, v. sol. alcohol. An isomeride [265°], got by treating acetophenone *o*-carboxylic anilide with conc. H_2SO_4, is sl. sol. alcohol.

DI-PHENYL METHYLENE DISULPHONE $CH_2(SO_2Ph)_2$. [119°]. Formed by oxidation of $CH_2(SPh)_2$ which is got by boiling CH_2Cl_2 with NaSPh (Fromm, *A.* 253, 161). Needles, v. sl. sol. boiling water.

DI-PHENYL-DI-METHYLENE DI-SULPHONE KETONE $C_{15}H_{14}S_2O_5$ *i.e.* $CO(CH_2SO_2Ph)_2$. [150°]. Got from $CHBr.CO.CH_2.SO_2Ph$ and $C_6H_5.SO_2Na$. Got also from $CO(CHCl_2)_2$ and $C_6H_5.SO_2Na$ (Otto, *B.* 19, 1542; 22, 1967). Small crystals (from HOAc). Yields an oxim [137°] and a phenyl-hydrazide [171°]. PhSH forms $(PhS)_2C(CH_2.SO_2Ph)_2$ [191°].

DI-PHENYL-METHYLENE-DI-THIO-GLYCOLLIC ACID $CPh_2(S.CH_2.CO_2H)_2$. [176°]. Formed by heating benzophenone with thioglycollic acid and $ZnCl_2$ (Bongartz, *B.* 21, 488). Needles (from dilute HOAc), insol. hot water.

PHENYL-TRIMETHYLENE-THIO-UREA $\mathrm{CS}<\begin{matrix}\mathrm{NH\ .CH_2}\\ \mathrm{NPh.CH_2}\end{matrix}>\mathrm{CH_2}$. [215°]. Formed by boiling $NHPh.C_3H_6.NH.CS.SNPhH_2.C_3H_6.NH_2$ with water (Goldenring, *B.* 23, 1172). White prisms.

Di-phenyl-methylene-ψ-thio-urea $C_{14}H_{12}N_2S$ *i.e.* $\mathrm{S}<\begin{matrix}\mathrm{C(NPh)}\\ \mathrm{CH_2}\text{——}\end{matrix}>\mathrm{NPh}$. [68°]. Formed from di-phenyl-thio-urea and CH_2I_2 (Foerster, *B.* 21, 1872). Thin needles, v. e. sol. alcohol.—$B'_2H_2PtCl_6$. Crystalline pp.

Di-phenyl-trimethylene-ψ-thio-urea $\mathrm{S}<\begin{matrix}\mathrm{C(NPh)-NPh}\\ \mathrm{CH_2.CH_2.CH_2}\end{matrix}$. [123°]. Formed from di-phenyl-thio-urea and trimethylene bromide (F.).

Di-phenyl-trimethylene-di-thio-di-urea $CH_2(CH_2.NH.CS.NPhH)_2$. Formed from phenyl-thiocarbimide, trimethylene-diamine, and alcohol (Lellmann a. Würthner, *A.* 228, 236). Plates [115°] or nodules [60°], v. sol. alcohol.

Tri-phenyl-trimethylene-di-thio-di-urea $NHPh.CS.NH.CH_2.CH_2.CH_2.NPh.CS.NHPh$. [145°]. Formed by heating phenyl-trimethylene-diamine (1 g.) with phenyl-thiocarbimide (2 g.) and alcohol (15 c.c.) (G.). Slender needles.

DIPHENYL-METHYLENE-*p*-TOLUIDINE $C_6H_4MeN{:}CPh_2$. (above 360°). Formed from Ph_2CCl_2 and *p*-toluidine (Pauly, *A.* 187, 214). Oil, split up by acids into *p*-toluidine and benzophenone.

PHENYL-TRIMETHYLENE-UREA $\mathrm{CO}<\begin{matrix}\mathrm{NPh.CH_2}\\ \mathrm{NH\ .CH_2}\end{matrix}>\mathrm{CH_2}$. [215°]. Formed by heating phenyl-amido-propyl-urea at 240° (Goldenring, *B.* 23, 1173). Yellowish plates, sl. sol. hot Aq.

Di-phenyl-trimethylene-urea $\mathrm{CO}<\begin{matrix}\mathrm{NPh.CH_2}\\ \mathrm{NPh.CH_2}\end{matrix}>\mathrm{CH_2}$. [156°]. Formed, together with $CH_2(CH_2.NPh.COCl)_2$ [102°], from di-phenyl-trimethylene-diamine and $COCl_2$ in benzene (Hanssen, *B.* 20, 782). Plates.

Tetra-phenyl-trimethylene-di-urea $CH_2(CH_2.NPh.CO.NHPh)_2$. [153°]. Formed from $CH_2(CH_2.NPh.COCl)_2$ and aniline (H.).

PHENYL TRIMETHYLENYL KETONE $\mathrm{C_6H_5.CO.CH}<\begin{matrix}\mathrm{CH_2}\\ \mathrm{CH_2}\end{matrix}$ or $\begin{matrix}\mathrm{CH\ :CPh}\\ \mathrm{CH_2.CH_2}\end{matrix}>\mathrm{O}$. *Benzoyl-trimethylene. Phenyl-furfurane dihydride* (239°) at 720 mm. V.D. 5·27 (calc. 5·04). Formed by heating its carboxylic acid at 200° (Perkin, jun., *B.* 16, 2140; *C. J.* 47, 842). Oil with aromatic odour. Alcoholic hydroxylamine forms the oxim in the cold, but by heating the ketone with alcoholic hydroxylamine hydrochloride at 135° there are formed $C_{33}H_{27}N_3O_3$ (a red amorphous powder) and $C_{30}H_{28}N_2O_2$ (a black brittle mass which forms deep-blue $B''H_2Cl_2$ and $B''H_2PtCl_6$).

Oxim. [87°]. Colourless plates.

PHENYL TRIMETHYLENYL KETONE CARBOXYLIC ACID $\begin{matrix}\mathrm{CH_2}\\ \mathrm{CH_2}\end{matrix}>\mathrm{CBz.CO_2H}$. [149°]. Formed by saponification of the ether. Monoclinic prisms; $a{:}b{:}c = 2{\cdot}380{:}1{:}2{\cdot}132$; $\beta = 83°4'$. M. sol. ether, sl. sol. water. Decomposed by water at 110° into phenyl oxypropyl ketone $CH_2OH.CH_2.CH_2Bz$, which when extracted with ether and dried over K_2CO_3 is found to have split off water, the resulting anhydride being possibly phenyl trimethylenyl ketone (Perkin, *C. J.* 51, 837).—AgA′: flocculent pp.

Ethyl ether Et_2A''. (282°) at 720 mm. Formed from benzoyl-acetic ether, ethylene bromide, and NaOEt (Perkin, *B.* 16, 2138; *C. J.* 47, 841). Oil.

Reference.—NITRO - PHENYL - TRIMETHYLENYL KETONE CARBOXYLIC ACID.

PHENYL-METHYL-ETHYLENE-DIAMINE $NH_2.CH_2.CH_2.NPhMe$. (255°). Formed by the action of HCl on $C_6H_4{:}C_2O_2{:}N.C_2H_4.NPhMe$ (Newman, *B.* 24, 2200). Liquid, v. sol. water and alcohol.—$B'C_6H_2(NO_2)_3OH$. [173°]. Needles.

Di phenyl di-methyl-ethylene-diamine $C_2H_4(NPhMe)_2$. The methylo-bromide $B''Me_2Br_2$, got by heating di-methyl-aniline with ethylene bromide (Hübner, *A.* 224, 346), crystallises in deliquescent prisms and yields $B''Me_2(OH)_2$, $B''Me_2Cl_2$, $B''Me_2PtCl_6$, $B''Me_2Cl_2 3HgCl_2$ [174°], $B''Me_2I_2$, $B''Me_2Cr_2O_7$, and $B''Me_2(C_6H_2N_3O_7)_2$ [124°].

PHENYL-METHYL-ETHYLENE DIKETONE *v.* ACETOPHENONE-ACETONE. Its carboxylic acid is described as ACETOPHENONE-ACETO-ACETIC ACID.

DI-PHENYL-DI-METHYL-*v*-ETHYLENE-DI-PYRROLE-DI-CARBOXYLIC ACID $\begin{matrix}\mathrm{CO_2H.C{:}CMe}\\ \mathrm{HC{:}CPh}\end{matrix}>\mathrm{N.C_2H_4.N}<\begin{matrix}\mathrm{CMe{:}C.CO_2H}\\ \mathrm{CPh{:}CH}\end{matrix}$. [181°]. Obtained by saponification of its ether, which is formed by mixing acetophenone-aceto-acetic ether with ethylene-diamine (Paal a. Schneider, *B.* 19, 3158). Crystalline solid. Sl. sol. alcohol, acetic acid, and conc. HCl, insol. other ordinary solvents. On heating above 180° it evolves CO_2, giving the free base.

Di-ethyl-ether Et_2A'': [197°]; plates; distillable under ordinary pressure; sol. alcohol, benzene, chloroform, and acetic acid, insol. water and petroleum-spirit.

PHENYL-METHYL-ETHYL-OSOTRIAZOLE $\mathrm{NPh}<\begin{matrix}\mathrm{N{:}CMe}\\ \mathrm{N{:}CEt}\end{matrix}$. (270°). Formed by condensation of the oxim-phenyl-hydrazide of $CH_3.CO.CO.C_2H_5$ (Pechmann, *A.* 262, 312). Needles. Yields a di-nitro- derivative [113°]. Oxidised by alkaline $KMnO_4$ to phenyl-methyl-triazole carboxylic acid.

PHENYL-METHYL-ETHYL-PYRAZOLE $\mathrm{NPh}<\begin{matrix}\mathrm{N=CH}\\ \mathrm{CEt{:}CMe}\end{matrix}$. (283°). S.G. $\frac{15}{4}$ 1·0476. Got by the action of phenyl-hydrazine on $C_2H_5.CO.CHMe.CHO$ (Claisen, *B.* 22, 3276).

Reference.—OXY-PHENYL-METHYL-ETHYL-PYRAZOLE.

TRI-PHENYL-METHYL-ETHYL-THIO-BIURET $C_2S_2N_3Ph_3MeEt$. [157°]. Formed from di-phenyl-ethyl-thio-urea and NPhMe.CSCl (Billeter a. Strohl, *B.* 21, 108). An isomeride [156°] is formed from di-phenyl-methyl-urea and NPhEt.CSCl. Both bodies crystallise in needles, sl. sol. alcohol.

PHENYL-METHYL-ETHYL-THIO-UREA CS(NHMe).NPhEt. Got from methyl thiocarbimide and ethyl-aniline (Gebhardt, *B.* 17, 3037). Crystalline solid.

Di-phenyl-methyl-ethyl-thio-urea CS(NPhMe).NPhEt. [49·5°]. Formed from methyl-aniline and NPhEt.COCl (Billeter, *B.* 20, 1632). Monoclinic crystals.

PHENYL-METHYL-FURFURANE $C_{11}H_{10}O$, *i.e.* $\begin{matrix}\mathrm{CH{:}CMe}\\ \mathrm{CH{:}CPh}\end{matrix}>\mathrm{O}$ or *Oxyphenyl-pentamethenyl* *hydride*  $\begin{matrix}CH_2.CH_2\\CPh{:}CH\end{matrix}\!>CO$. [40°]. (c. 238°). Formed by heating phenythronic acid, and prepared by warming acetophenone-acetone with fuming HClAq, the yield being 65 p.c. (Paal, *B.* 17, 2759; Fittig, *B.* 21, 2134; *A.* 250, 222). Needles or prisms, insol. water and alkalis, volatile with steam. Br forms $C_{11}H_9Br_5O$ [210°]. Phenyl-hydrazine forms a compound [165°-175°], crystallising from alcohol in golden spangles.

Tetrahydride  $\begin{matrix}CH_2.CHMe\\CH_2.CHPh\end{matrix}\!>O$. (c. 230°). Formed by reduction in alcoholic solution by Na. Oil, miscible with alcohol and ether.

PHENYL-METHYL-FURFURANE CARBOXYLIC ACID $C_{12}H_{10}O_3$ *i.e.*  $\begin{matrix}CO_2H.C{:}CMe\\HC{:}CPh\end{matrix}\!>O$. [181°]. Formed by boiling dehydro-acetophenone-acetoacetic ether (*cf.* vol. i. p. 36) with HClAq (Paal, *B.* 17, 2762). Needles. Boiling Ac_2O forms an acetyl derivative $C_{14}H_{12}O_4$ [83°], reconverted by NaOHAq into the parent acid.—KA'.—AgA': crystalline pp.

Phenyl-methyl-furfurane carboxylic acid $C_{12}H_{10}O_3$ *i.e.*  $\begin{matrix}CH{:}CMe\\CO_2H.C{=}CPh\end{matrix}\!>O$ or  $\begin{matrix}CO_2H.CH\ .CPh\\CH_2.CO\end{matrix}\!>CH$. *Phenuvic acid.* [145°]. Formed by heating phenythronic acid (Fittig, *B.* 21, 2134). Its ether is obtained from chloro-acetone and sodium benzoyl-acetic ether (Colefax, *C. J.* 59, 190). Long silky needles.—CaA'_2 2aq.—BaA_2'aq.—AgA': amorphous pp.

Phenyl-methyl-furfurane dicarboxylic acid $C_{13}H_{10}O_5$ *i.e.*  $\begin{matrix}CO_2H.CH\ .CPh\\CH_2.CO\end{matrix}\!>C.CO_2H$ or  $\begin{matrix}CO_2H.C{:}CMe\\CO_2H.C{:}CPh\end{matrix}\!>O$. *Phenythronic acid* [193°]. Formed by saponifying its ether with boiling baryta (Fittig, *A.* 250, 216). Silky needles, m. sol. hot water, v. sol. alcohol.—CaA'' 3aq. S. 5.—BaA'' aq.—Ag_2A'': crystalline pp.

Mono-ethyl ether EtHA''. [112°]. Formed by the action of Ac_2O on a mixture of sodium succinate and benzoyl-acetic ether.—$Ca(EtA'')_2$: crystalline nodules (from alcohol).—$Ba(EtA'')_2$.—AgEtA'': white amorphous pp.

Di-ethyl ether Et_2A''. [44·5°].

PHENYL-METHYL-GLYCOCOLL *v.* PHENYL-METHYL-AMIDO-ACETIC ACID.

PHENYL-METHYL-GLYOXALINE $C_{10}H_{10}N_2$ *i.e.*  $CMe\!<\!\begin{matrix}N-CH\\NH.CPh\end{matrix}$. [159°]. Formed by heating phenyl-methyl-oxazole with alcoholic NH_3 at 230° (Lewy, *B.* 22, 2195). Needles, v. sl. sol. alcohol. **Salts.**—B'HCl. [242°]. Needles.—$B'_2H_2PtCl_6$ 2aq. [212°]. Yellow prisms.

Phenyl-di-methyl-glyoxaline $C_{11}H_{12}N_2$ *i.e.*  $CPh\!<\!\begin{matrix}N-CMe\\NH.CMe\end{matrix}$. [230°-234°]. Formed by heating diacetyl with benzoic aldehyde and alcoholic NH_3 (Wadsworth, *C. J.* 57, 8). Needles (from benzene).—$B'_2H_2PtCl_6$: needles.

Di-phenyl-methyl-glyoxaline  $CMe\!<\!\begin{matrix}N-CPh\\NH.CPh\end{matrix}$. [235°]. Formed by the action of aldehyde and NH_3 on benzil (Japp, *C. J.* 49, 466; 51, 557; *C. J. Proc.* 3, 34). Trimetric crystals; $a{:}b{:}c = 1·207{:}1{:}1·920$. Crystallises with diphenylglyoxaline (1 mol.), the compound melting at 218°.

PHENYL-METHYL-HYDANTOIC ACID $C_6H_5.NH.CO.NH.CH(CH_3).CO_2H$ [170°]. Formed by the combination of phenyl cyanate with alanine and boiling the product with alcoholic KOH (Kühn, *B.* 17, 2884). Glistening scales.

PHENYL-METHYL-HYDANTOÏN  $CHPh\!<\!\begin{matrix}CO\ .NMe\\NH.CO\end{matrix}$ [162°]. Formed from phenyl-hydantoïn, KOMe, and MeI (Pinner, *B.* 21, 2325). Needles, sl. sol. cold alcohol.

***s*-PHENYL-METHYL-HYDRAZINE** $C_6H_5NH.NHMe$. *Hydrazo - phenyl - methyl.* Got by saponification of its dibenzoyl derivative, which is formed by heating NPhBz.NBzH with NaOMe and MeI (Tafel, *B.* 18, 1740). Obtained also by the action of alkalis on nitroso-antipyrin (Knorr, *A.* 238, 137). Oil, oxidised by HgO to PhN:NMe. Reduces Fehling's solution and ammoniacal $AgNO_3$ in the cold.—$B'_2H_2SO_4$. [180°].—**Oxalate:** white needles.

Di-benzoyl derivative PhNBz.NMeBz. [145°]. Crystals, v. sol. alcohol and ether.

u - **Phenyl - methyl - hydrazine** $NPhMe.NH_2$. (227° i.V.) at 745 mm. Formed by converting methyl-aniline into phenyl-methyl-nitrosamine, and reducing this body (5 pts.) by zinc-dust (20 pts.), HOAc (10 pts.), and water (35 pts.) at 0° (E. Fischer, *A.* 190, 152; 236, 199).

Properties.—Colourless oil, turning brown in air; m. sol. hot water, miscible with alcohol.

Reactions.—1. *Nitrous acid* yields NPhMe.NO, water, and N_2O.—2. *Diazobenzene nitrate* solution forms PhN_3 and methyl-aniline nitrate.—3. HgO added to its solution in chloroform produces NPhMe.N:N.NPhMe [137°].—4. Reacts with *aldehydes* and *ketones* in the same way as phenyl-hydrazine, forming products of condensation; thus benzoic aldehyde forms NPhMe.N:CHPh [104°] (Ebers, *A.* 227, 340), acetophenone forms NPhMe.N:CMePh [50°], acetone forms $C_{10}H_{14}N_2$ (216°) (Degen, A. 236, 152), propionic aldehyde yields $C_{10}H_{14}N_2$ (198° at 170 mm.), glucose yields $C_6H_{10}O_5{:}N.NPhMe$ [171°], while benzil yields $Ph.CO.CPh{:}N_2PhMe$ [56°] and $N_2PhMe{:}CPh.CPh{:}N_2PhMe$ [180°] (Kohlrausch, *A.* 253, 16; Fischer, *B.* 22, 87).—5. CS_2 at 100° forms $CS(NH.NPhMe)_2$ [c. 168°] (Stahel, *A.* 258, 250).—6. *Nitroso-aniline* forms $C_{13}H_{14}N_4O$ [151°], while *nitroso-dimethylaniline* gives $C_{15}H_{18}N_4O$ [141°] (O. Fischer, *B.* 22, 622).—7. With PhN:SO it forms PhNMe.N:SO [77°] crystallising from alcohol in yellow needles (Michaelis, *A.* 270, 120).

Salt.—$B'_2H_2SO_4$: plates, v. e. sol. water.

Acetyl derivative NPhMe.NHAc. [93°]. Prisms, m. sol. hot water. Converted by Na and MeI into NPhMe.NMeAc [68°], which is not decomposed by alkalis, but gives methylaniline when boiled with HClAq.

Benzoyl derivative NPhMe.NHBz. [153°]. Formed by heating NPhH.NHBz with NaOMe and MeI. Needles (Tafel, *B.* 18, 1743).

Sulphonic acid $SO_3H.C_6H_4NMe.NH_2$. Formed by heating with fuming H_2SO_4 (Pfülf, *A.* 239, 219). Plates.—NaA' aq: slender needles.

PHENYL-METHYL-IMESATIN *v.* *Anilide of Methyl* ISATIN.

DI-PHENYL METHYLIMIDO-DI-ETHYL DISULPHONE $NMe(C_2H_4.SO_2Ph)_2$. Formed by heating $NH(C_2H_4.SO_2Ph)$ with alcohol and MeI at 115° (Otto, *J. pr.* [2] 30, 335).—B'HCl [221°].

PHENYL-METHYL-INDOLE $C_{15}H_{13}N$ *i.e.* $C_6H_4{<}\substack{CH\\NMe}{>}CPh$. [101°]. Formed by heating the phenyl-hydrazide of acetophenone with $ZnCl_2$ at 130° (Fischer, *B.* 19, 1565; Degen, *A.* 236, 155). Formed also by heating $CH_2Bz.NMePh$ with $ZnCl_2$ at 180° (Staedel, *B.* 21, 2196; Culmann, *B.* 21, 2596), and by heating the isomeric $C_6H_4{<}\substack{CPh\\NMe}{>}CH$ with $ZnCl_2$ at 220° (Ince, *A.* 253, 40). Needles (from alcohol). Colours pine-wood, moistened with HCl, dark-red.

Acetyl derivative $C_6H_4{<}\substack{CAc\\NMe}{>}CPh$. [136°]. Formed by heating $CH_2Ac.CPh{:}N.NMePh$ with $ZnCl_2$ at 150°. Needles (from dilute HOAc).

Phenyl-methyl-indole $C_6H_4{<}\substack{CPh\\NMe}{>}CH$. [65°]. Formed from phenyl-acetic aldehyde and phenyl-methyl-hydrazine (Ince, *A.* 253, 38). Crystals, v. sol. benzene. Colours acidified pine-wood reddish-violet.—$B'C_6H_3N_3O_7$. [90].

Phenyl-methyl-indole $C_6H_4{<}\substack{CPh\\NH}{>}CMe$. [60°]. Formed by heating the phenyl-hydrazide of benzyl methyl ketone with $ZnCl_2$ (Trenkler, *A.* 248, 110). Prisms (from ligroïn).—**Picrate**: [142°]; v. sol. benzene.

PHENYL METHYL KETONE *v.* ACETOPHENONE.

Phenyl methyl diketone $C_6H_5.CO.CO.CH_3$. *Acetyl-benzoyl.* (217°). S.G. $\frac{14}{4}$ 1·1041. S. ·26 at 20°. Formed by distilling its oxim Bz.C(NOH)Me with dilute H_2SO_4 (Von Pechmann, *B.* 21, 2119; 22, 2129) or with isoamyl nitrite (Manasse, *B.* 21, 2177). Heavy oil, volatile with steam.

Oxim $C_6H_5.CO.C(NOH).CH_3$. *Nitroso-propiophenone.* [114°]. Formed by the action of isoamyl nitrite and HCl or NaOEt on the ketone (Claisen a. Manasse, *B.* 22, 529). Prepared by the action of nitrous acid on benzoyl-propionic ether (1 mol.) and KOHAq (3 mols.) (P.; Gudeman, *B.* 22, 562). Needles (from hot water), forming a deep-yellow solution in alkalis. $SnCl_2$ and HCl yield hydroxylamine and phenyl methyl diketone. Reduced by sodium-amalgam to a base which crystallises from alcohol in needles [108°].

Di-oxim Ph.C(NOH).C(NOH).Me. [236°]. Formed from the mono-oxim and hydroxylamine hydrochloride. Needles (from dilute alcohol).

Phenyl hydrazide $C_{15}H_{14}N_2O$. [145°]

Di-phenyl-di-hydrazide $CMe(N_2HPh).CPh(N_2HPh)$. [105°]. Yellow crystals, v. sol. ether.

Oxim-phenyl-hydrazide $CPh(N_2HPh).CMe{:}NOH$. [202°]. White needles.

Phenyl methyl triketone. *Mono-oxim* $C_6H_5.CO.C(NOH).CO.CH_3$. [124°]. Formed by the action of nitrous acid on phenyl methylene methyl diketone (Ceresole, *B.* 17, 814). Needles, v. sol. benzene, sol. alkalis.

Di-oxim $C_6H_5.C(NOH).C(NOH).CO.CH_3$. [178°]. Formed by heating the mono- oxim with hydroxylamine hydrochloride. Needles, insol. cold water, sol. alkalis.

PHENYL-METHYL-KETONE CARBOXYLIC ACID *v.* BENZOYL-ACETIC ACID and ACETOPHENONE CARBOXYLIC ACID.

PHENYL-METHYL-MALONIC ACID *v.* BENZYL-MALONIC ACID.

Tri-phenyl-methyl-malonic ether $CPh_3.CH(CO_2Et)_2$. [133·5°]. Formed from CPh_3Br and sodium malonic ether (Henderson, *B.* 20, 1014; *C. J. Proc.* 2, 251). Needles (from alcohol). Yields tri-phenyl-propionic acid when heated with alcoholic potash.—NaA′aq: needles.—BaA'_2aq.—AgA′: minute white crystals.

PHENYL - DI - METHYL - NAPHTHALENE TETRAHYDRIDE *v.* METHRONOL.

PHENYL - METHYL - (β)-NAPHTHOTRIAZINE DIHYDRIDE $C_{18}H_{15}N_3$ *i.e.* $C_{10}H_6{<}\substack{N.CHMe\\N.NPh}$. Formed by adding aldehyde to a mixture of benzene-azo-(β)-naphthylamine and alcohol (Goldschmidt a. Poltzer, *B.* 24, 1004). Plates, v. sol. hot alcohol.—B′HCl. [252°].—$B'_2H_2PtCl_6$. Yellow needles.—B′MeI. [244°].—$B'_2Me_2PtCl_6$. [260°]. Yellow needles.

PHENYL - METHYL - (β)-NAPHTHYL-THIO-UREA $C_{18}H_{16}N_2S$ *i.e.* $NPhMe.CS.NHC_{10}H_7$. [127°]. Formed from (β)-naphthyl thiocarbimide and methyl-aniline (Gebhardt, *B.* 17, 2091). Yellow needles.

PHENYL - METHYL - NITROSAMINE *v.* *Nitrosamine* of METHYL-ANILINE, vol. iii. p. 285.

PHENYL-METHYL-OSOTRIAZOLE $NPh{<}\substack{N{:}CH\\N{:}CMe}$. (242°). S.G. $\frac{17}{4}$ 1·1071. Formed by oxidising the diphenyl-hydrazide of pyruvic aldehyde and warming the resulting $\substack{NPh.N{:}CH\\NPh.N{:}CMe}$. Formed also by the action of NaOH on $CH_3.C(N_2HPh).CH{:}NOAc$ (Pechmann, *B.* 21, 2751; *A.* 262, 279). Oil. Yields a tri-nitro- derivative [138°], and a sulphonic acid, of which the Na salt crystallises in hexagonal plates.

Phenyl-di-methyl-osotriazole $NPh{<}\substack{N{:}CMe\\N{:}CMe}$. [35°]. (354°). Formed by heating the phenyl-hydrazide-oxim of diacetyl with Ac_2O (P.). Crystalline, insol. water, sol. conc. HClAq, but reppd. by water. Yields a di-nitro- derivative [139°] and a tri-nitro- derivative [227°].

PHENYL-METHYL-OSOTRIAZOLE CARBOXYLIC ACID $NPh{<}\substack{N{:}CMe\\N{:}C.CO_2H}$. [198°]. Formed by oxidising phenyl-di-methyl-osotriazole with $KMnO_4$ (Pechmann, *A.* 262, 308). Needles, v. sl. sol. water.—AgA′: white pp.

PHENYL-METHYL-OXAMIDE $C_9H_{10}N_2O_2$ *i.e.* $NHPh.C_2O_2.NHMe$. [180°]. Formed from $NHMe.C_2O_2.OEt$ and aniline (Wallach, *A.* 184, 70). Needles.

PHENYL-METHYL-OXANTHRANOL $C_{21}H_{16}O_2$ *i.e.* $C_6H_3Me{<}\substack{CPh(OH)\\CO}{>}C_6H_4$. [195°]. Formed by oxidation of phenyl-methyl-anthranol with $K_2Cr_2O_7$ and HOAc (Hemilian, *B.* 16, 2360). Trimetric tables, v. sol. hot alcohol, insol. alkalis. Conc. H_2SO_4 forms a purple solution.

Isomeride $\left[1{:}\substack{4\\5}\right]C_6H_3Me{<}\substack{CPh(OH)\\CO}{>}C_6H_4$. [213°]. Formed by oxidising di-phenyl-tolyl-methane *o*-carboxylic acid with K_2CrO_4 and conc. H_2SO_4 (Hemilian, *B.* 19, 3064). Prisms, insol. alkalis. Reduced by zinc-dust to a phenyl-methyl-anthranol.

PHENYL-METHYL-OXAZOLE $C_{10}H_9NO$ *i.e.*

$O<\begin{matrix}CPh:CH\\CMe:N\end{matrix}$. [45°]. (242°). Formed by heating acetamide with bromo-acetophenone at 125° (Blümlein, *B.* 17, 2579; Lewy, *B.* 20, 2576; 21, 924). Needles (from alcohol). Yields benzoic acid on oxidation. Na and alcohol form an oily tetrahydride $C_{10}H_{13}NO$ (251°), which yields crystalline $C_{10}H_{12}BzNO$ [140°]. HI and P give oily $C_{10}H_{18}$ (c. 275°). Conc. nitric acid forms $C_{10}H_8(NO_2)NO$ [157°], which may be reduced to $C_{10}H_8(NH_2)NO$ [115°]. Hydroxylamine, phenylhydrazine, and hot zinc-dust have no action.—$B'HCl$.—$B'_2H_2PtCl_6$ 2aq.—$B'C_6H_3N_3O_7$. [134°].

Phenyl-methyl-oxazole
$O<\begin{matrix}CPh:N\\CMe:CH\end{matrix}$. (240°). Formed by boiling benzamide with chloroacetone (Lewy, *B.* 21, 2193). Oil with fruity odour.—$B'_2H_2PtCl_6$ 2aq. [170°]. Yellow needles.

Dihydride
$O<\begin{matrix}CPh{=}N\\CHMe.CH_2\end{matrix}$. (244°). Formed by the action of KOH on bromo-propyl-benzamide in hot aqueous or alcoholic solution, the product being distilled with steam (Gabriel a. Heymann, *B.* 23, 2499). Liquid. Partly converted, by evaporation with excess of HClAq (or HBrAq), into β-chloro- (or bromo-) propyl-benzamide [78°] (or [73°]). Boiling with an equivalent of HClAq yields β-amido-propyl benzoate. —$B'_2H_2PtCl_6$.—$B'_2H_2Cr_2O_7$.—$B'C_6H_3N_3O_7$.[167°].

PHENYL-TRI-METHYL-PHENYL-CARBINOL $C_{16}H_{18}O$ *i.e.* $CHPh(OH).C_6H_2Me_3$. *Phenyl-mesitylene carbinol.* [34°]. (330°). Formed by reducing benzoyl-mesitylene with sodium-amalgam (Louise, *Bl.* [2] 45, 231; *A. Ch.* [6] 6, 209). Prisms. Boiling diluted H_2SO_4 (1:1) converts it into $(C_{16}H_{17})_2O$ [137°].

Ethyl ether $C_{16}H_{17}EtO$. [32°]. Prisms.

Acetyl derivative $C_{16}H_{17}AcO$. [52°].

Benzoyl derivative. [94°]. Crystals.

DIPHENYL TRIMETHYLPHENYLENE DIKETONE $(C_6H_5.CO)_2C_6HMe_3$. [117°]. Formed by heating $C_6H_5.CO.C_6H_2Me_3$ with BzCl and $AlCl_3$ (Louise, *C. R.* 98, 151; *A. Ch.* [6] 6, 236). Prisms, sol. alcohol and ether.

Di-phenyl tetramethylphenylene diketone $C_6Me_4(CO.C_6H_5)_2$. [270°]. A product of the action of BzCl and $AlCl_3$ on durene (Friedel a. Crafts, *C. R.* 88, 880). Minute prisms, sol. benzene, almost insol. boiling alcohol.

PHENYL METHYLPHENYL KETONE *v.* PHENYL TOLYL KETONE.

Phenyl dimethylphenyl ketone *v.* PHENYL XYLYL KETONE.

Phenyl trimethylphenyl ketone $C_6H_5.CO.C_6H_2Me_3$[1:2:4:6]. *Benzoyl-mesitylene. Phenyl mesityl ketone.* [35°]. (319°). V.D. 8·18. Formed from BzCl, mesitylene, CS_2, and $AlCl_3$ (Elbs, *J. pr.* [2] 35, 485; *cf.* Louise, *A. Ch.* [6] 6, 200; *C. R.* 96, 499; Claus, *B.* 19, 2879). Prisms (from alcohol), sol. acetone and ligroïn. Does not react with hydroxylamine (Smith, *B.* 24, 4052).

Reactions.—1. Conc. H_2SO_4 or $H_2S_2O_7$ at 100° gives benzoic acid and mesitylene sulphonic acid.—2. Conc. H_2SO_4 at 50° forms phenyl-mesityl-ketone sulphonic acid $C_{16}H_{15}O.SO_3H$.—3. A mixture of fuming HNO_3 and $H_2S_2O_7$ forms two trinitro-derivatives [188°] and [145°]. 4. HNO_3 (S.G. 1·1) at 200° forms benzoyl-uvitic or phenyl-tolyl-ketone dicarboxylic acid.—5. *Potash-fusion* gives mesitylene and KOBz.—6. HI reduces it to benzyl-mesitylene.—7. *Sodium-amalgam* yields the carbinol.—8. *Chromic acid* oxidises it to $C_6H_5.CO.C_6H_2Me_2.CO_2H$.

Phenyl tetra-methyl-phenyl ketone $C_6H_5.CO.C_6HMe_4$. [119°]. (343°). Formed by heating durene with BzCl and $AlCl_3$ at 120° (Friedel, Crafts, a. Ador, *C. R.* 88, 980). Crystalline. Decomposed by potash-fusion into benzoic acid and durene. Reduced by HIAq and P at 240° to $CH_2Ph.C_6HMe_4$ [60·5°], (310°).

Isomeride $C_6H_5.CO.C_6HMe_4$. [63°]. (300°). *Formed from BzCl and isodurene (got from* toluene, MeCl, and $AlCl_3$). Crystals (Essner a. Gossin, *Bl.* [2] 42, 171).

PHENYL TRIMETHYLPHENYL KETONE *o*-CARBOXYLIC ACID $C_6H_2Me_3.CO.C_6H_4.CO_2H$. [212°]. Formed from phthalic anhydride, mesitylene, and $AlCl_3$ (F. Meyer a. Gresly, *B.* 15, 639; *A.* 234, 234). Needles (from alcohol).

Phenyl tetramethylphenyl ketone carboxylic acid *v.* TETRA-METHYL-BENZOYL-BENZOIC ACID.

PHENYL-TRIMETHYLPHENYL-THIO-UREA $NHPh.CS.NHC_6H_2Me_3$. [193°]. Formed by heating methyl-thiocarbimide with an alcoholic solution of aniline (Eisenberg, *B.* 15, 1014).

PHENYL-DI-METHYL-PHOSPHINE PMe_2Ph. (192° cor.). S.G. $\frac{11}{}$ ·977. Formed from PCl_2Ph and $ZnMe_2$ in benzene (Michaelis, *A.* 181, 359). Liquid, oxidised by air. Combines with CS_2 forming PMe_2PhCS_2 crystallising in red plates and yielding $B'_2H_2PtCl_6$ (Czimatis, *B.* 15, 2017).

Salts.—$B'HCl$: crystalline, sl. sol. ether, v. e. sol. alcohol.—$B'2HCl$. Liquid.—$B'_2H_2PtCl_6$.

Methylo-iodide PMe_3PhI. [205°].

Bromo-ethylo-bromide $PMe_2Ph(C_2H_4Br)Br$. [173°]. Formed from PMe_2Ph and $C_2H_4Br_2$ (Gleichmann, *B.* 15, 199). Yields $(B'(C_2H_4Br)Br)_2PtCl_4$ and the unstable $B'C_2H_4Br_2$. An alcoholic solution of phenyl-di-methyl-phosphine forms $(PMe_2Ph)_2C_2H_4Br_2$ [above 300°], S. (alcohol) 2 at 21°, which gives unstable $(PMe_2Ph)_2C_2H_4Br_6$ [171°].

Di-phenyl-methyl-phosphine $PMePh_2$. (284°). S.G. $\frac{15}{}$ 1·08. Formed from $PClPh_2$ and $ZnMe_2$ (Michaelis a. Link, *A.* 207, 210). Liquid. Yields PMe_2Ph_2I [241°], $(PMe_2Ph_2)_2PtCl_6$ [218°], and $PMePh_2O$ [112°] (Michaelis a. La Coste, *B.* 18, 2116; *A.* 229, 316).

PHENYL-DI-METHYL-PHOSPHINE *p*-CARBOXYLIC ACID $C_6H_4(CO_2H).PMe_2$. The methylo-chloride $C_6H_4(CO_2H).PMe_3Cl$, formed by oxidation of the methylo-chloride of *p*-tolyl-di-methyl-phosphine, crystallises in prisms (Michaelis, *B.* 15, 2018). It yields the compounds $B'Me_2PtCl_6$, $C_6H_4(CO_2H).PMe_3OH$ 2aq, and $C_6H_4(CO_2H)PMe_3.SO_4H$.

Oxide $C_6H_4(CO_2H).POMe_2$. [243°]. Formed by oxidation of the ethyleno-bromide of tolyl-di-methyl-phosphine. Colourless prisms.

PHENYL METHYL PROPYLENE DIKETONE $C_6H_5.CO.CHEt.CO.CH_3$. (265°–270°). Formed from benzoyl-acetone, Na, and EtI (Claisen a. Lowman, *B.* 21, 1152). Liquid.

PHENYL-METHYL-PROPYLENE-ψ-THIO-UREA
$\begin{matrix}CHMe.S\\CH_2{-}N\end{matrix}{>}CNPhMe$. (c. 300°). Formed by heating methyl-aniline with allyl thiocarbimide and HClAq at 100° (Prager, *B.* 22, 2996). —$B'_2H_2PtCl_6$. [184°].—$B'C_6H_3N_3O_7$. [125°].

TRI-PHENYL-METHYL-PROPYL-DI-THIO-BIURET $C_2S_2N_3Ph_3MePr$. [110°]. Formed from NPhMeCSCl and di-phenyl-propyl-thio-urea (Billeter a. Strohl, *B.* 21, 109). Small yellow pyramids. An isomeride [111°] is formed from NPhPr.CSCl and di-phenyl-methyl-thio-urea.

DI-PHENYL-METHYL-PROPYL-THIO-UREA NPhMe.CS.NPhPr. [56°]. Formed from $CSCl_2$, propyl-aniline, and MeCl or from $CSCl_2$, methyl-aniline, and PrCl (Billeter a. Strohl, *B.* 21, 103). Colourless prisms.

DI-PHENYL-DI-METHYL-PYRAZINE $CMe<\begin{smallmatrix}N:CPh\\CPh.N\end{smallmatrix}>CMe$. [124°]. Formed when phenyl amido-ethyl ketone is allowed to stand with NH_3Aq (Schmidt, *B.* 22, 3253).—B'HCl: needles.—$B'_2H_2PtCl_6$.

Di-phenyl-methyl-pyrazine dihydride $N<\begin{smallmatrix}CPh.CPh\\CH_2.CHMe\end{smallmatrix}>N$. [112°]. Formed from benzil and propylene-diamine (Strache, *B.* 21, 2363). Needles, v. sol. benzene; m. sol. alcohol.

Di-phenyl-tetra-methyl-pyrazine dihydride $C_{20}H_{22}N_2$ *i.e.* $NPh<\begin{smallmatrix}CMe:CMe\\CMe:CMe\end{smallmatrix}>NPh$. [108°]. (281°). Formed by heating β-bromo-β-acetyl-propionic acid (1 pt.) with aniline (3 pts.) at 95°; the yield being 70 p.c. of the theoretical amount (Wolff, *B.* 20, 429). Satiny plates, v. sol. ether and conc. HClAq.

References.—NITRO- and OXY-DI-PHENYL-METHYL-PYRAZINE.

PHENYL-METHYL-PYRAZOLE $NPh<\begin{smallmatrix}N=CMe\\CH:CH\end{smallmatrix}$. [37°]. (255°). S.G. ^{15} 1·085.

Formation.—1. By heating oxy-phenyl-methyl-pyrazole $NPh<\begin{smallmatrix}N=CMe\\CO.CH_2\end{smallmatrix}$ with zinc-dust (Knorr, *A.* 238, 199).—2. From acetoacetic aldehyde, phenyl-hydrazine, and HOAc (Claisen, *B.* 21, 1147; 24, 1888).—3. By heating its carboxylic acid at 210° (Ach, *A.* 253, 55).—4. From oxy-phenyl-methyl-pyrazole dihydride and P_2S_5 (Knorr a. Duden, *B.* 25, 766).

Properties.—Needles, v. sol. alcohol and ether; volatile with steam. Oxidised by $KMnO_4$ to phenyl-pyrazole carboxylic acids [146°].

Salt.—$B'H_2PtCl_6$: orange needles.

Dihydride $NPh<\begin{smallmatrix}N=CMe\\CH_2.CH_2\end{smallmatrix}$. [75°]. Formed by reducing the base in alcoholic solution with Na. Flat needles, m. sol. alcohol.

Phenyl-methyl-pyrazole $NPh<\begin{smallmatrix}N - CH\\CMe:CH\end{smallmatrix}$. (262°). Formed by distilling its dicarboxylic acid (Knorr a. Laubmann, *B.* 22, 178). Got also from acetone, oxalic acid, and phenyl-hydrazine (Claisen a. Roosen, *B.* 24, 1890). Yields phenyl-pyrazole carboxylic acid [183°] on oxidation by $KMnO_4$.—$B'_2H_2PtCl_6$ 2aq. [147°].

Phenyl-di-methyl-pyrazole $NPh<\begin{smallmatrix}N=CMe\\CMe:CH\end{smallmatrix}$. (273° i.V.). Formed by heating its carboxylic acid (Knorr, *B.* 20, 1103) and by warming acetyl-acetone with phenyl-hydrazine (K.; Combes, *Bl.* [2] 50, 145). Oil, volatile with steam.—$B'_2H_2PtCl_6$ 4aq. Decomposes at 186°.

Methylo-iodide B'MeI. [190°]. Crystals, v. sol. water.—$B'_2Me_2PtCl_6$. Decomposes at 220°.

Dihydride $NPh<\begin{smallmatrix}N=CMe\\CHMe.CH_2\end{smallmatrix}$. (290° i.V.). Formed by adding Na to a boiling alcoholic solution of the base.

Phenyl-tri-methyl-pyrazole. *Dihydride* $NPh<\begin{smallmatrix}N=CMe\\CMe_2.CH_2\end{smallmatrix}$. Formed by heating mesityl oxide with phenyl-hydrazine (Fischer a. Knoevenagel, *A.* 239, 203). Oil, v. e. sol. ether and alcohol, sl. sol. water. Its solution in dilute HCl gives a violet colour with $K_2Cr_2O_7$.—$B'_2H_2PtCl_6$: crystalline pp.

Di-phenyl-methyl-pyrazole $C_{16}H_{14}N_2$ *i.e.* $NPh<\begin{smallmatrix}N - CPh\\CMe:CH\end{smallmatrix}$. [63°]. (335° or 355°). Formed by heating its carboxylic acid at 250°, and also by warming benzoyl-acetone with phenyl-hydrazine (Knorr, *B.* 18, 314; Fischer, *B.* 18, 2185). Insol. water, v. sol. alcohol. Weak base. Yields $C_{16}H_{13}BrO_2$ [75°]. — $B'_2H_2PtCl_6$ aq. — B'MeI. [187°].—$B'_2Me_2PtCl_6$. [241°]. Orange-red needles.

Dihydride $C_{16}H_{16}N_2$. [109°]. Long prisms (from ether). Its acid solution is coloured intensely red by nitrous acid.

Di-phenyl-methyl-pyrazole $C_{16}H_{14}N_2$ *i.e.* $NPh<\begin{smallmatrix}N\ CH\\CPh:CMe\end{smallmatrix}$. [47°]. (365°). Formed by heating its carboxylic acid, and also, together with its dihydride, by distilling the phenyl-hydrazide of benzylidene-acetone (Knorr, *B.* 18, 931; 20, 1100). Weak base.—$B'_2H_2PtCl_6$: red prisms.—B'MeI. [192°].—$B'_2Me_2PtCl_6$. [229°].

Dihydride $C_{16}H_{16}N_2$. [114°]. (c. 350°). Prisms. Its solutions fluoresce blue and give a blue colour with nitrous acid.

Tri-phenyl-methyl-pyrazole. *Tetrahydride* $NPh<\begin{smallmatrix}NMe\ .CHPh\\CHPh.CH_2\end{smallmatrix}$. [110°]. Formed by the action of Na and boiling alcohol on tri-phenyl-pyrazole methylo-iodide (Knorr a. Laubmann, *B.* 21, 1205). Insol. water, v. sol. alcohol. Resinified by conc. HNO_3.

References.—OXY-AMIDO- and OXY-PHENYL-METHYL-PYRAZOLE.

PHENYL-METHYL-PYRAZOLE CARBOXYLIC ACID $NPh<\begin{smallmatrix}N=C.CO_2H\\CMe:CH\end{smallmatrix}$. [106°]. Formed from acetone, oxalic acid, and phenyl hydrazine (Claisen a. Roosen, *B.* 24, 1891).

Methyl ether MeA'. (256° at 109 mm.).

Amide. [146°].

Phenyl-methyl-pyrazole carboxylic acid $NPh<\begin{smallmatrix}N=CMe\\C(CO_2H):CH\end{smallmatrix}$. [166°]. Formed by heating $NPh<\begin{smallmatrix}N\ :CMe\\CO.C(OH)\end{smallmatrix}>CH$ with HClAq at 170° (Ach, *A.* 253, 54). Needles, sol. hot alcohol.

Phenyl-methyl-pyrazole dicarboxylic acid $C_{12}H_{10}N_2O_4$ *i.e.* $NPh<\begin{smallmatrix}N - C.CO_2H\\CMe:C.CO_2H\end{smallmatrix}$. [198°]. Formed by oxidising phenyl-di-methyl-pyrazole carboxylic acid with alkaline $KMnO_4$ (Knorr a. Laubmann, *B.* 22, 177). Needles (from water).

Phenyl-di-methyl-pyrazole carboxylic acid $NPh<\begin{smallmatrix}N=CMe\\CMe:C.CO_2H\end{smallmatrix}$. [197°]. Got by saponifying its ether, which is obtained from ethylidene-acetoacetic ether and phenyl-hydrazine (Knorr, *B.* 20, 1102). Needles, v. sl. sol. water.—KA'.

Ethyl ether EtA'. [68°]. (286° at 260 mm.).

Di-phenyl-methyl-pyrazole carboxylic acid $C_{17}H_{14}N_2O_2$ *i.e.* $NPh<\begin{matrix}N\text{—}CPh\\CMe:C.CO_2H\end{matrix}$ [205°]. Got from its ether, which is obtained by the action of phenyl-hydrazine on benzoyl-aceto-acetic ether (Knorr a. Blank, *B.* 18, 311). Sol. alkalis and conc. HClAq, insol. water.

Ethyl ether EtA'. [122°].

Di-phenyl-methyl-pyrazole carboxylic acid $NPh<\begin{matrix}N{=}C.CO_2H\\CPh:CMe\end{matrix}$. [194°]. Formed from its ether, which is got by mixing benzylidene-aceto-acetic ether with phenyl-hydrazine (Knorr a. Blank, *B.* 18, 931). Crystalline, v. sol. alkalis and acids.

Ethyl ether EtA'. [110°].

References.—Nitro- and Oxy-phenyl-methyl-pyrazole carboxylic acid.

PHENYL-DI-METHYL-PYRIDAZINE. *Dihydride* $NPh<\begin{matrix}NH\ .CMe\\CMe:CH\end{matrix}>CH$. [82°]. (176° at 730 mm.). Formed by heating the dicarboxylic acid at 220° (Knorr, *B.* 18, 304, 1568). Volatile with steam. Insol. water and alkalis, sol. conc. HClAq. Colours pinewood, dipped in HClAq, red. H_2SO_4 added to its solution in HOAc containing phenanthraquinone gives a deep-red colour.

Dicarboxylic acid of the dihydride $C_{14}H_{14}N_2O_4$. Obtained from its ether, which is formed by mixing acetic acid solutions of di-acetyl-succinic ether and phenyl-hydrazine. Needles (from HOAc).—BaA''.

Ethyl ether Et_2A''. [127°]. Prisms.

Reference.—Oxy-phenyl-methyl-pyridazine.

PHENYL-DI-METHYL-PYRIDINE $N\lessdot\begin{matrix}CMe:CH\\CMe.CH\end{matrix}\gtrdot CPh$. [55°]. (287°) at 731 mm. Formed by distilling its dicarboxylic acid with lime (Bally, *B.* 20, 2591). Prisms (from ether). —B'HCl 3aq : needles.—$B'_2H_2PtCl_6$ 4aq : needles. — $B'HNO_3$. [177°]. Needles. — $B'H_2Cr_2O_7$. Needles.—$B'C_6H_3N_3O_7$. [222°]. Needles.

Methylo-iodide B'MeI. Granules, sl. sol. water.—$B'_2Me_2PtCl_6$. [250°].

Hexahydride $C_5NH_8Me_2Ph$. (274°) at 731 mm. Got by adding Na to an alcoholic solution of phenyl-di-methyl-pyridine. Liquid. Does not give a pp. with picric acid.—B'HCl.—$B'HNO_3$. [210°].—$B'_2H_2PtCl_6$. [237°]. Plates.

References.—Nitro- and Oxy-phenyl-di-methyl-pyridine.

PHENYL-METHYL-PYRIDINE DICARBOXYLIC ACID $C_{14}H_{11}NO_4$ *i.e.* $CO_2H.C_6H_4.C\lessdot\begin{matrix}CH.CH\ :CMe\\C(CO_2H):N\end{matrix}$. [201°]. Formed by oxidising methyl-(β)-naphthoquinoline by $KMnO_4$ in acid solution (F. Seitz, *B.* 22, 257). Needles (containing aq) or anhydrous prisms. $FeSO_4$ colours its aqueous solution lemon-yellow. — Na_2A'' 2aq. — ZnA'' 1½aq. — CuA'' 1½aq : minute bluish-green plates.

Phenyl-di-methyl-pyridine carboxylic acid $N\lessdot\begin{matrix}CMe:C(CO_2H)\\CMe\text{——}CH\end{matrix}\gtrdot CPh$. [190°]. Got from its ether, which is formed by heating the mono-ethyl ether of the dicarboxylic acid (Hantzsch, *B.* 17, 2911). Small prisms (containing 2aq), v. sol. hot water.—CuA'_2.—$(HA')_2H_2PtCl_6$ aq.

Ethyl ether EtA'. (316°-320°). Thick liquid. Yields $(EtA')_2H_2PtCl_6$ [196°] and also EtA'MeI [c. 206°], which is converted by alcoholic potash into $C_{15}H_{15}NO_2$ [161°], split up by HClAq at 180° into acetic acid and oxy-phenyl-di-methyl-pyridine [112°].

Phenyl-di-methyl-pyridine dicarboxylic acid $N\lessdot\begin{matrix}CMe:C(CO_2H)\\CMe.C(CO_2H)\end{matrix}\gtrdot CPh$.

Mono-ethyl ether HEtA''. [180°]. Formed by boiling the di-ethyl ether with alcoholic KOH (1 mol.) (H.). Cubes (from alcohol).

Di-ethyl ether Et_2A''. [67°]. Formed by oxidising its dihydride with nitrous acid.

Dihydride of the di-ethyl ether $N\lessdot\begin{matrix}CHMe.CH(CO_2Et)\\CMe\text{——}C(CO_2Et)\end{matrix}\gtrdot CPh$. [157°]. Formed by heating a mixture of benzoic aldehyde, aceto-acetic ether, and alcoholic NH_3 (Schiff a. Puliti, *B.* 16, 1607; Bally, *B.* 20, 2591). Formed also by mixing benzylidene-acetoacetic ether with β-imido-butyric ether (Beyer, *B.* 24, 1666). Colourless crystals, sol. alcohol.

(β)-Phenyl-di-methyl-pyridine dicarboxylic acid $[1:2]CO_2H.C_6H_4.C\lessdot\begin{matrix}CMe\ :\ CH\\C(CO_2H).N\end{matrix}\gtrdot CMe$. Formed by oxidising di-methyl-(β)-naphthoquinoline with $KMnO_4$ (Reed, *J. pr.* [2] 35, 311). Syrup.—AgA'.

Reference.—Oxy-phenyl-di-methyl-pyridine carboxylic acid.

PHENYLTRI-METHYL-PYRIDYL KETONE CARBOXYLIC ETHER $N\lessdot\begin{matrix}CMe.C(CO_2Et)\\CMe:C(CO.Ph)\end{matrix}\gtrdot CMe$. Formed by the action of nitrous acid on its dihydride.—$B'HNO_3$: white plates.—B'HCl. [192°]. Prisms.—$B'_2H_2PtCl_6$: needles.

Dihydride $NH<\begin{matrix}CMe:C(CO_2Et)\\CMe:C(CO.Ph)\end{matrix}>CHMe$. [187°]. Formed from ethylidene-acetoacetic ether and $C_6H_5.CO.CH_2.C(NH).CH_3$ (Beyer, *B.* 24, 1667). Yellowish plates.

Methyl derivative of the dihydride $NMe<\begin{matrix}CMe:C(CO_2Et)\\CMe:C(CO.Ph)\end{matrix}>CHMe$. [87°]. Formed, in like manner, by the action of the methylimide of benzoyl-acetone on ethylidene-acetoacetic ether (B.). Yellowish-white needles.

PHENYL-METHYL-PYRIMIDINE $C_{11}H_{10}N_2$ *i.e.* $CPh\lessdot\begin{matrix}N.CMe\\N:CH\end{matrix}>CH$. [74°-78°]. Formed by distilling the oxy-derivative (from benzamidine and acetoacetic ether) with zinc-dust (Pinner, *B.* 18, 2850). Colourless needles.—$B'_2H_2Cl_2PtCl_4$. [190°].

References.—Oxy- and Oxy-amido-phenyl-methyl pyrimidine.

PHENYL-METHYL-PYRROLE $C_{11}H_{11}N$ *i.e.* $NH<\begin{matrix}CMe:CH\\CPh:CH\end{matrix}$. [101°]. Got by heating acetophenone-acetone $CH_2Bz.CH_2Ac$ with alcoholic NH_3 at 150°; the yield being 70 p.c. of the theoretical (Paal, *B.* 18, 367). Plates, v. sol. alcohol. May be sublimed. Gives a purple-red colour with isatin and H_2SO_4.

Phenyl-di-methyl-pyrrole $C_{12}H_{13}N$ *i.e.* $NPh<\begin{matrix}CMe:CH\\CMe.CH\end{matrix}$. [52°]. (252°). Formed by distilling its dicarboxylic acid at 244° (Knorr, *A.* 236, 306).

DI-PHENYL-METHYL-PYRROLE $C_{17}H_{15}N$ i.e. $\mathrm{NPh}{<}\begin{array}{l}\mathrm{CPh:CH}\\ \mathrm{CMe:CH}\end{array}$. [84°]. Formed by heating the carboxylic acid [226°] to above its melting-point (Lederer a. Paal, *B.* 18, 2596). Large tables.

Tetra-phenyl-methyl-pyrrole $\mathrm{NMe}{<}\begin{array}{l}\mathrm{CPh:CPh}\\ \mathrm{CPh:CPh}\end{array}$. [214°]. Formed by heating bidesyl $C_{28}H_{22}O_2$ [255°] with aqueous methylamine at 150° (Fehrlin, *B.* 22, 554). Groups of minute needles, sol. hot alcohol and ether.

Reference.—Oxy - tri - phenyl - methyl - pyrrole.

PHENYL-METHYL-PYRROLE CARBOXYLIC ACID $\mathrm{NH}{<}\begin{array}{l}\mathrm{CMe:C.CO_2H}\\ \mathrm{CPh:CH}\end{array}$. [c. 190°]. Got by saponification of its ether, which is formed by allowing acetophenone-acetoacetic ether to stand with excess of NH_3Aq (Lederer a. Paal, *B.* 18, 2593). Flat needles (from HOAc).

Ethyl ether EtA'. [120°]. Needles.

Phenyl-di-methyl-pyrrole carboxylic ether $C_{15}H_{17}NO_2$ *i.e.* $\mathrm{NMe}{<}\begin{array}{l}\mathrm{CMe:C.CO_2Et}\\ \mathrm{CPh:CH}\end{array}$. [112°]. Formed from acetophenone acetoacetic ether and $NMeH_2Aq$ (L. a. P.). Plates (from alcohol-ether), v. e. sol. alcohol.

Phenyl-di-methyl-pyrrole ***m*****-carboxylic acid** $\mathrm{CO_2H.C_6H_4.N}{<}\begin{array}{l}\mathrm{CMe:CH}\\ \mathrm{CMe:CH}\end{array}$. [135°]. Formed by heating acetonyl-acetone with *m*-amido-benzoic acid and alcohol (Paal, *B.* 19, 558). Flat crystals, sl. sol. water, v. sol. alcohol.

Phenyl-di-methyl-pyrrole di-carboxylic acid $\mathrm{CO_2H.CH_2.N}{<}\begin{array}{l}\mathrm{CMe:C.CO_2H}\\ \mathrm{CPh:CH}\end{array}$. [152°]. Got by saponifying its ether. Small needles (from alcohol), sl. sol. water.

Ethyl ether Et_2A''. [131°]. Got by allowing acetophenone-acetoacetic ether to stand with glycocoll and HOAc (Paal a. Schneider, *B.* 19, 3160). Needles (from HOAc), sl. sol. water.

Phenyl-di-methyl-pyrrole dicarboxylic acid $\mathrm{NPh}{<}\begin{array}{l}\mathrm{CMe:C.CO_2H}\\ \mathrm{CMe:C.CO_2H}\end{array}$. Got from its ether. Powder, decomposing at 224° into CO_2 and phenyl-di-methyl-pyrrole.—CaA''.—$CaH_2A''_2$: prisms.

Ethyl ether Et_2A''. [38°]. (280°) at 500 mm. Formed by warming di-acetyl-succinic ether with aniline and HOAc (Knorr, *A.* 236, 305). Crystals.

Di-phenyl-methyl-pyrrole carboxylic acid $\mathrm{NPh}{<}\begin{array}{l}\mathrm{CPh:CH}\\ \mathrm{CMe:C.CO_2H}\end{array}$. [226°]. Obtained by saponification of its ether, which is formed by boiling acetophenone-aceto-acetic ether with an acetic acid solution of aniline (Lederer a. Paal, *B.* 18. 2595). Small needles (from acetic acid).

Ethyl ether A'Et: [100°]; prisms.

Di-phenyl-methyl-pyrrole di-*o*-carboxylic acid $\mathrm{NMe}{<}\begin{array}{l}\mathrm{C(C_6H_4.CO_2H):CH}\\ \mathrm{C(C_6H_4.CO_2H):CH}\end{array}$. [231°]. Formed from $C_2H_4(CO.C_6H_4.CO_2H)_2$ and methylamine in alcohol at 100° (Baumann, *B.* 20, 1489). Deep-yellow plates, insol. water, sl. sol. ether.

Di-phenyl-methyl-pyrrole dicarboxylic acid $\mathrm{CO_2H.C_6H_4.N}{<}\begin{array}{l}\mathrm{CMe:C.CO_2H}\\ \mathrm{CPh:CH}\end{array}$. [210°]. Formed by saponifying its ether, which is got from acetophenone-acetoacetic ether, *m*-amido-benzoic acid, and HOAc (Paal a. Schneider, *B.* 19, 3162). Needles (from dilute alcohol).

Ethyl ether EtA'. [160°]. Needles.

Reference.—Oxy - phenyl - methyl - pyrrole carboxylic acid.

PHENYL-METHYL-QUINAZOLINE DIHYDRIDE $C_{15}H_{14}N_2$ *i.e.* $\mathrm{C_6H_4}{<}\begin{array}{l}\mathrm{N\,-CMe}\\ \mathrm{CH_2.NPh}\end{array}$. [60°]. Formed by reduction of the acetyl derivative of *o*-nitro-benzyl-aniline with tin and HClAq (Paal a. Krecke, *B.* 23, 2638). Rosettes of white needles, insol. water, m. sol. ligroïn. The tin double chloride melts at 122°.—B'HCl 2aq. [257°].—$B'_2H_2PtCl_6$. Flat orange needles. Decomposes at 223°.

Reference.—Oxy - phenyl - methyl - quinazoline.

(*Py.* 1,3) - PHENYL-METHYL-QUINOLINE $\mathrm{C_6H_4}{<}\begin{array}{l}\mathrm{CPh:CH}\\ \mathrm{N{=\!=}CMe}\end{array}$. [100°]. Formed by boiling an alcoholic solution of *o*-amido-benzophenone with acetone and KOHAq (Geigy a. Königs, *B.* 18, 2406; 19, 2428). Obtained also from paraldehyde, acetophenone, HCl, and aniline, and by heating benzoyl-acetone-anilide $C_{16}H_{15}NO$ with H_2SO_4 on the water-bath (Beyer, *J. pr.* [2] 33, 420; *B.* 20, 1771). Tables (from ether).—$B'H_2SO_4$. [236°].—$B'_2H_2PtCl_6$ 2aq. [225°]. Its acid solutions fluoresce blue. By heating with phthalic anhydride and $ZnCl_2$ at 150° it is converted into the phthalone $C_{21}H_{15}NO_2$ [270°], which crystallises from alcohol or HOAc in sparingly-soluble orange-red crystals.

(*Py.* 3,1)-Phenyl-methyl-quinoline $C_{16}H_{13}N$ *i.e.* $\mathrm{C_6H_4}{<}\begin{array}{l}\mathrm{CMe:CH}\\ \mathrm{N{=\!=}CPh}\end{array}$. *Flavoline.* [65°]. (374°). V.D. 7·7 (calc. 7·6). Formed by distilling flavenol with zinc-dust. Prepared by adding a little dilute (10 p.c.) NaOHAq to a solution of equimolecular quantities of *o*-amido-acetophenone and acetophenone, and then heating on the water-bath (Fischer, *B.* 15, 1503; 16, 68; 19, 1037). Thick tables. Yields flavaniline on nitration and reduction. Salts.—B'HCl 2aq.—$B'_2H_2PtCl_6$: reddish-yellow needles.—B'MeI. [185°] (Bernthsen a. Hess, *B.* 18, 34). Converted by KOHAq into a strongly alkaline solid 'methyl-flavolinium hydrate.'—$B'_2Me_2PtCl_6$.

(*Py.* 3,2)-Phenyl-methyl-quinoline $\mathrm{C_6H_4}{<}\begin{array}{l}\mathrm{CH:CMe}\\ \mathrm{N{=}CPh}\end{array}$. [53°]. (above 300°). Formed by heating a mixture of CHPh:CMe.CHO, aniline, and conc. HClAq at 200° (Miller a. Kinkelin, *B.* 19, 527). Trimetric prisms, v. sol. alcohol and ether.—$B'_2H_2PtCl_6$: orange plates.—$B'C_6H_3N_3O_7$. [202°]. Large yellow plates.

(*B.* 2)-Phenyl-(*Py.* 4)-methyl-quinoline tetrahydride $C_{16}H_{17}N$ *i.e.* $\begin{array}{l}\mathrm{CPh:CH.C.CH_2\,.CH_2}\\ \mathrm{CH\;:CH.C.NMe.CH_2}\end{array}$. Formed by reducing (*B.* 2)-phenyl-quinoline methylo-chloride with tin and HClAq (La Coste a. Sorger, *A.* 230, 24). Amorphous powder, insol. cold water.—B'HCl.—B'HI.—$B'C_6H_3N_3O_7$. [147°].—B'MeI aq. [195°]. Yellow plates.

(*Py.* 3)-Phenyl-(*B.* 4)-methyl-quinoline $\begin{array}{l}\mathrm{CH:CH\;\,.C.CH:CH}\\ \mathrm{CH:CMe.C.N{=}CPh}\end{array}$. [50°]. Formed by distilling its (*Py.* 1)-carboxylic acid with soda-lime (Doebner a. Giesecke, *A.* 242, 299). Plates (from alcohol).—$B'_2H_2PtCl_6$. Brick-red needles.

(*Py.* 3)-Phenyl-(*B.* 2)-methyl-quinoline  $\begin{array}{l}\text{CMe:CH.C.CH:CH}\\ \text{CH :CH.C.N :CPh}\end{array}$ [68°]. (above 360°). Got by distilling its carboxylic acid with soda-lime (D. a. G.). Small yellow needles (from dilute alcohol).—$B'_2H_2PtCl_6$: golden needles.

References.—NITRO- and OXY-PHENYL-METHYL-QUINOLINE.

(*Py.* 3)-PHENYL-(*B.* 4)-METHYL-QUINOLINE (*Py.* 1)-CARBOXYLIC ACID $C_{17}H_{13}NO_2$. [245°]. Formed by heating equi-molecular proportions of *o*-toluidine, benzoic aldehyde, and pyruvic acid in alcoholic solution on the water-bath (Doebner a. Giesecke, *A.* 242, 298). Small yellow crystals (from alcohol), v. sl. sol. hot water.—CuA'_2aq.—AgA'aq: needles (from Aq).

(*Py.* 3)-Phenyl-(*B.* 2)-methyl-quinoline (*Py.* 1)-carboxylic acid. [228°]. Formed in like manner from *p*-toluidine (D. a. G.). Yellow needles (from alcohol).—CuA'_2.—PbA'_2.—AgA'.—$H_2A'_2H_2PtCl_6$: golden needles, v. sl. sol. hot Aq.

Reference.—OXY-PHENYL-METHYL-QUINOLINE CARBOXYLIC ACID.

PHENYL (*Py.* 3)-METHYL-(*B.* 2)-QUINOLYL KETONE  $C_6H_5.CO.C_6H_3<\begin{array}{l}\text{CH:CH}\\ \text{N=CMe}\end{array}$ [68°]. (above 300°). Formed from amido-benzophenone, paraldehyde, and HClAq at 100° (Hinz, *A.* 242, 323). Needles (from water) or plates (from alcohol).—$B'_2H_2PtCl_6$2aq.—$B'_2H_2Cr_2O_7$.—B'MeI. [220°]. Small dark-green needles; v. sol. water.

Phenyl (*Py.* 3)-methyl-(*B.* 4)-quinolyl ketone. [108°]. Formed by boiling *o*-amido-benzophenone with dilute H_2SO_4 and paraldehyde (Geigy a. Königs, *B.* 18, 2406). Matted needles (from dilute alcohol).

PHENYL-DI-METHYL-QUINOLYL-THIO-UREA $NHPh.CS.NH.C_{11}H_{10}N$. [159°]. Formed by heating phenyl-thiocarbimide with amido-di-methyl-quinoline (Marckwald, *B.* 23, 1025). Prisms, v. sol. hot alcohol.—$B'_2H_2PtCl_6$: pp.

PHENYL-METHYL-QUINOXALINE  $\begin{array}{l}\text{CMe:CH.C.N:CPh}\\ \text{CH :CH.C.N:CH}\end{array}$ [79°]. Formed by reducing $C_6H_3Me(NO_2).NH.CH_2Bz$ with $SnCl_2$ and HCl (Lellmann a. Donner, *B.* 23, 171). Needles, v. sol. alcohol.—$B'HgCl_2$. [223°]. White needles.

Phenyl-methyl-quinoxaline  $\begin{array}{l}\text{CMe:CH.C.N:CH}\\ \text{CH :CH.C.N:CPh}\end{array}$ [135°]. Formed, together with the preceding isomeride, by the action of chloro-acetophenone on tolylene-*o*-diamine (Hinsberg, *A.* 237, 370). Formed also by warming phenyl-glyoxylic aldehyde $C_6H_5.CO.CHO$ with tolylene-*o*-diamine sulphate and NaOAc (Pechmann, *B.* 20, 2905). Needles, v. sol. hot alcohol and ether.

Phenyl-di-methyl-quinoxaline  $C_6H_3Me<\begin{array}{l}\text{N:CMe}\\ \text{N:CPh}\end{array}$ [48°]. Formed by boiling phenyl methyl diketone with tolylene-*o*-diamine in ether (Müller a. Pechmann, *B.* 22, 2130). V. sol. most solvents.

Di-phenyl-methyl-quinoxaline $C_{21}H_{16}N_2$ *i.e.*  $C_6H_3Me<\begin{array}{l}\text{N:CPh}\\ \text{N:CPh}\end{array}$ [111°]. Formed by heating benzil with tolylene-*o*-diamine in alcoholic solution (Hinsberg, *B.* 17, 322). Silvery plates. May be distilled. Weak base. Nearly insol. Aq.

Di-phenyl-*v*-methyl-quinoxaline dihydride  $C_6H_4<\begin{array}{l}\text{NMe.CHPh}\\ \text{N=CPh}\end{array}$ [133°]. Formed by heating phenylene-methyl-*o*-diamine with benzoïn at 165° (Fischer a. Busch, *B.* 24, 2682). Yellow needles, m. sol. alcohol. Its solutions fluoresce greenish-yellow.

Reference.—OXY-PHENYL-METHYL-QUINOXALINE.

PHENYL-METHYL-ROSINDULINE  $C_{10}H_5(NPh)<\begin{array}{l}\text{N}\\ \text{NPh}\end{array}>C_6H_3Me\ \left[\begin{array}{l}1\\ 2\end{array}4\right]$. [232°]. Formed from benzene-azo-*p*-tolyl-(α)-naphthylamine (Fischer a. Hepp, *A.* 256, 243). Reddish-brown bronzed plates. Split up by conc. HClAq at 200° into aniline and methyl-rosindone.

PHENYL-METHYL-SUCCINIC ACID PHENYL-PYROTARTARIC ACID.

Phenyl-tri-methyl-succinic acid $C_{13}H_{16}O_4$ *i.e.* $CH_2Ph.CH(CO_2H).CMe_2.CO_2H$. [140°]. Formed from bromo-isobutyric ether and sodium benzyl-malonic ether, the resulting ether (200°–220°) being saponified (Bischoff, *B.* 24, 1060). Short needles (from water), v. sol. alcohol and ether.

Di-phenyl-di-methyl-succinic acid. *Nitrile* CPhMe(CN).CPhMe.CN. [227°]. Formed from CHPhMe.CN by treatment with NaOEt and I (Chalanay a. Knoevenagel, *B.* 25, 289). Insol. benzene, sl. sol. alcohol.

PHENYL-METHYL-SULPHAMIC ACID $NPhMe.SO_3H$. Formed from $ClSO_3H$ and methyl-aniline in chloroform (Traube, *B.* 24, 362).—NH_4A'. Turns violet in air. Decomposed by boiling HClAq into methyl-aniline and H_2SO_4. The potassium salt is a crystalline powder, sl. sol. alcohol, v. sol. water.

PHENYL-DI-METHYL SULPHAMIDE $SO_2(NMe_2)(NHPh)$. [85°]. Formed from $NMe_2.SO_2Cl$ and aniline (Behrend, *A.* 222, 128). Needles (from ether). Yields $SO_2(NMe_2)(NPhNa)$, crystallising in needles, v. sol. water and alcohol.

PHENYL METHYL SULPHIDE PhSMe. (188°). Formed from $Pb(SPh)_2$ and MeI at 100° (Obermeyer, *B.* 20, 2926). Liquid.

PHENYL METHYL SULPHONE $C_7H_8SO_2$ *i.e.* $C_6H_5.SO_2.CH_3$. [89°]. Formed from benzene sulphinic acid, NaOEt, and MeI at 100°, and also by boiling $C_6H_5.SO_2.CH_2.CO_2H$ with alcoholic potash (Michael a. Palmer, *Am.* 6, 254; 7, 65; Otto a. Rössing, *B.* 18, 156; 21, 652; 22, 1449, 1452; 23, 755). Plates (from hot water), v. e. sol. alcohol and ether.

PHENYL METHYL SULPHONE ω-CARBOXYLIC ACID *v.* PHENYL-SULPHONO-ACETIC ACID.

PHENYL-METHYL-THIAZOLE $C_{10}H_9NS$ *i.e.*  $N\ll\begin{array}{l}\text{CMe:CH}\\ \text{CPh.S}\end{array}$. (279° cor.). Formed from thiobenzamide and chloro-acetone in alcohol (Hubacher, *A.* 259, 236). Oil.

Phenyl-methyl-thiazole  $N\ll\begin{array}{l}\text{CPh:CH}\\ \text{CMe.S}\end{array}$. [68·5°]. (284° cor.). Formed from thioacetamide and ω-bromo-acetophenone (Hantzsch, *B.* 21, 913; *A.* 250, 269). Weak base. Not attacked in boiling alcoholic solution by sodium (Schatzmann, *A.* 261, 7).—B'HCl: sl. sol. Aq.

Phenyl-methyl-thiazole. *Dihydride*  $N\ll\begin{array}{l}\text{CH}_2\text{.CHMe}\\ \text{CPh.S}\end{array}$. Formed by boiling propylene bromide with thiobenzamide (Gabriel a. Heymann, *B.* 24, 785). Yellowish liquid.—*Picrate* $B'C_6H_3N_3O_7$: crystalline.

Di-phenyl-methyl-thiazole  $N\ll\begin{array}{l}\text{CPh:CPh}\\ \text{CMe.S}\end{array}$.

°]. Formed from thioacetamide and bromo-oxybenzoïn in alcohol (Hubacher, *A.* 259, 4). Stellate groups of needles, insol. water. Hydrochloride: [97°]; white crystals from dilute HClAq).

PHENYL-METHYL-THIAZOLE CARBOXYLIC ACID  $N<\begin{smallmatrix}CMe:C.CO_2H\\CPh.S\end{smallmatrix}$. [203°]. Formed by saponifying its ether. Needles, sl. sol. ether.

Ethyl ether EtA′. [43°]. Formed from thiobenzamide and chloro-acetic ether (Hubacher, *A.* 259, 237).

PHENYL (α)-METHYL-THIENYL KETONE $C_6H_5.CO.C_4H_2MeS$. [124°]. Formed by heating $C_4H_2Me(HgCl)S$ with BzCl at 100° (Volhard, *A.* 267, 181; *cf.* Ernst, *B.* 19, 3280). Needles (from ligroïn).

TRI-PHENYL-DI-METHYL-DI-THIO-BIURET $C_{22}H_{21}N_3S_2$ *i.e.* $NPh(CS.NPhMe)_2$ or CS(NPhMe).S.C(NPh)(NPhMe). [202°]. Formed from Cl.CS.NPhMe and aniline (Billeter a. Strohl, *B.* 21, 108). Needles, v. sl. sol. cold alcohol.

PHENYL-METHYL-DI-THIO-CARBAMIC ACID NPhMe.CS.SMe. [88°]. Formed by heating NPhMe.C(NMe).SMe. or NPhMe.C(NH).SMe with CS_2 at 160° (Bertram, *B.* 25, 51). Plates.

PHENYL-METHYL-THIOCARBAMIC CHLORIDE NPhMe.CS.Cl. [35°]. Formed from methyl-aniline and $CSCl_2$ (Billeter, *B.* 20, 1631). Yellowish crystals. Converted by alcohol into $(NPhMe.CS)_2O$ [116·5°].

PHENYL-METHYL-THIO-SEMI-CARBAZIDE NHPh.NH.CS.NHMe. [89°]. Formed from methyl-thiocarbimide and phenyl-hydrazine (Dixon, *C. J.* 57, 262). Trimetric prisms, v. sl. sol. cold water. H_2SO_4 forms an azure-blue solution. $CuSO_4$ gives a deep-blue colour, and $FeCl_3$ a greenish-blue.

Phenyl-methyl-thio-semi-carbazide NHPh.CS.NH.NHMe. [143°]. Formed from methyl-hydrazine and phenyl-thiocarbimide (Brüning, *A.* 253, 11). Prisms (from alcohol).

Di-phenyl-methyl-thio-semi-carbazide NPhMe.NH.CS.NHPh. [154°]. Formed from phenyl-methyl-hydrazine and phenyl-thiocarbimide (Fischer, *A.* 190, 166). V. sol. hot alcohol.

PHENYL-METHYL-THIOCARBIZINE  $CS<\begin{smallmatrix}NPh\\NMe\end{smallmatrix}$. [123°]. Formed from phenyl-thiocarbizine and MeI at 100° (Fischer, *A.* 212, 330). Tables (from water). Not attacked by nitrous acid.

PHENYL-METHYL-THIOHYDANTOÏC ACID $NHPh.CS.NH.CHMe.CO_2H$. Formed from alanine and phenyl-thiocarbimide in alcohol (Marckwald, *B.* 24, 3280; *cf.* Aschan, *B.* 17, 421).—KA′: minute needles.

PHENYL-METHYL-THIOHYDANTOÏN  $CS<\begin{smallmatrix}NPh.CO\\NH-CHMe\end{smallmatrix}$. [184°]. Formed by treating phenyl-methyl-thiohydantoïc acid (*v. supra*) with HCl. Small prisms (from alcohol). Split up by HClAq at 150° into aniline, alanine, CO_2, and CS_2.

Phenyl-di-methyl-thiohydantoïn  $CS<\begin{smallmatrix}NPh.CO\\NH.CMe_2\end{smallmatrix}$. [67°]. Formed from phenyl-thiocarbimide and α-amido-isobutyric acid (Marckwald, *B.* 24, 3282). Crystals, sl. sol. Aq.

PHENYL-METHYL-THIOPHENE $C_{11}H_{10}S$ *i.e.*  $S<\begin{smallmatrix}CMe:CH\\CPh:CH\end{smallmatrix}$. [51°]. (271° uncor.). Got by heating acetophenone-acetone with P_2S_3 at 125°, the yield being 70 p.c. of the theoretical amount (Paal, *B.* 18, 367). Needles, volatile with steam. Gives the indophenine reaction.

Phenyl-methyl-thiophene  $S<\begin{smallmatrix}CMe:CH\\CH:CPh\end{smallmatrix}$. [73°]. Formed by heating $CH_2Ac.CHPh.CO_2Na$ with P_2S_3 or P_2S_5 (Paal a. Püschel, *B.* 20, 2558). Plates, v. sol. hot alcohol. Gives the indophenine reaction on warming. Br forms $C_{11}H_6Br_4S$ [137°].

***s*-PHENYL-METHYL-THIO-UREA** $C_8H_{10}N_2S$ *i.e.* CS(NHPh)(NHMe). [1[illegible]3°]. Formed from methyl-thiocarbimide and aniline (Gebhardt, *B.* 17, 3038). Six-sided tables. Yields NH_2Me and $CS(NHPh)_2$ on boiling with aniline.

***u*-Phenyl-methyl-thio-urea** $CS(NH_2)(NPhMe)$. [107°]. Formed from methyl-aniline hydrochloride and potassium sulphocyanide (Gebhardt, *B.* 17, 2094). Tables (from alcohol) or prisms (from hot water).

Phenyl-methyl-ψ-thio-urea MeS.C(NH)(NHPh). [71°]. Formed by warming phenyl-thio-urea with MeI and alcohol (Bertram, *B.* 25, 49). Colourless crystals, sl. sol. hot water. Converted by dilute H_2SO_4 at 160° into MeS.CO.NHPh.—B′HI. [147°].—$B'H_2SO_4$. [171°].—$B'_2H_2SO_4$. [171°].—$B'HNO_3$. [113°].—B′HOAc. [115°].—$B'_2H_2PtCl_6$. [184°].—$B'C_6H_2(NO_2)_3OH$. [175°]. Yellow plates.

Phenyl-di-methyl-thio-urea CS(NHMe)(NPhMe). [114°]. Formed from methyl-thiocarbimide and methyl-aniline (G.).

Phenyl-di-methyl-ψ-thio-urea MeS.C(NH)(NPhMe). Formed from phenyl-methyl-ψ-thio-urea and methyl iodide (B.). Oil. Converted by dilute H_2SO_4 at 160° into MeS.CO.NPhMe [54°].—B′HI. [184°].—$B'C_6H_3N_3O_7$. Small prisms.

Phenyl-tri-methyl-ψ-thio-urea $C_{10}H_{14}N_2S$ *i.e.* MeS.C(NMe)(NPhMe). *Methyl-imido-methyl-phenyl-carbamic thiic methyl ether.* Formed by methylation of phenyl-di-methyl-ψ-thio-urea (B.).—B′HI. [c. 184°].—$B'_2H_2PtCl_6$. [c. 174°].—$B'C_6H_3N_3O_7$. [126°]. Lemon-yellow crystals.

Di-phenyl-methyl-thio-urea CS(NHPh)(NPhMe). [87°]. (205°). Formed from phenyl-thiocarbimide and methyl-aniline (G.). Prisms, v. sol. hot alcohol. Decomposed into the parent substances by distillation with steam. Boiling aniline yields $CS(NHPh)_2$ and methyl-aniline.

Di-phenyl-methyl-ψ-thio-urea MeS.C(NPh)(NHPh). [110°]. Formed from $CS(NHPh)_2$ and MeI. Conc. HClAq at 150° yields aniline and methyl-mercaptan.—B′HI.

Di-phenyl-di-methyl-thio-urea $CS(NPhMe)_2$. [72·5°]. Formed from NPhMe.CS.Cl and methyl-aniline (Billeter, *B.* 20, 1631). Prisms (from ligroïn).

Di-phenyl-di-methyl-ψ-thio-urea MeS.C(NPh)(NPhMe). (above 300°). Formed from CS(NHPh)(NPhMe) and MeI (Bertram, *B.* 25, 57). CS_2 at 160° forms $NPhMe.CS_2Me$.—B′HI. Crystalline meal, sl. sol. hot water.

Reference.—OXY-DI-PHENYL-METHYL-ψ-THIO-UREA.

PHENYL-METHYL-UREA $C_8H_{10}N_2O$ *i.e.* $CO(NH_2)(NPhMe)$. [82°]. Formed from methyl-aniline hydrochloride and potassium cyanate (Gebhardt, *B.* 17, 2095). Thin crystals.

Phenyl-di-methyl-urea $CO(NMe_2)(NPhMe)$. Formed from $NMe_2.COCl$ and aniline (Michler a. Escherich, *B.* 12, 1163). Crystals (from alcohol).

Di-phenyl-methyl-urea $CO(NPhMe)(NHPh)$. [104°]. (204°). Formed from phenyl cyanate and methyl-aniline (G.). Small needles.

Di-phenyl-di-methyl-urea $CO(NPhMe)_2$. [121°]. (c. 350°). Formed from $NPhMe.COCl$ and methyl-aniline (Michler a. Zimmermann, *B.* 12, 1165). Tables (from alcohol).

PHENYL-(β)-NAPHTHACRIDINE

$C_{10}H_6<\begin{matrix}CPh\\N\end{matrix}>C_{10}H_6$. [297°]. **S.** (alcohol) ·04 at 15°; **S.** (benzene) ·29 at 18°. Formed by heating a mixture of di-(β)-naphthylamine with BzCl or with benzoic acid and P_2O_5 or $ZnCl_2$ (Claus a. Richter, *B.* 17, 1595; Ris, *B.* 17, 2029; Klopsch, *B.* 18, 1586). Needles, v. sol. hot benzene.—B'HCl.—$B'_2H_2PtCl_6$: yellow needles.

Dihydride $C_{10}H_6<\begin{matrix}CHPh\\NH\end{matrix}>C_{10}H_6$. Got from benzoic aldehyde (1 mol.) and (β)-naphthylamine (2 mols.) in presence of condensing agents (Claisen, *A.* 237, 273). Oxidised to phenyl-naphthacridine.

(β)-**PHENYL-NAPHTHALENE** $C_{16}H_{12}$ *i.e.* $C_{10}H_7.C_6H_5$. [102°]. V.D. 7·12 (calc. 7·05). Formed by passing a mixture of naphthalene and bromo-benzene through a red-hot tube (Watson Smith, *B.* 12, 2049; *C. J.* 39, 546; *C. J. Proc.* 5, 70). Formed also by the action of H_2SO_4 (80 g.) diluted with water (44 g.) on $CHPh(OH).CH_2OH$ (Zincke a. Breuer, *A.* 226, 23; 240, 137). Fluorescent plates. May be sublimed. Gives rise on oxidation to a quinone $C_{16}H_{10}O_2$ [110°].

A **hydrocarbon** $C_{16}H_{12}$ [104°] got by distilling chrysoquinone with soda-lime is perhaps identical with the above (Graebe, *B.* 6, 66; 7, 792; Schmidt, ***J. pr.*** [2] 9, 285).

(α)-**Phenyl-naphthalene dihydride** *v.* ATRONENE.

Reference.—OXY-AMIDO-PHENYL-NAPHTHALENE.

DI-PHENYL-NAPHTHAMIDINE $C_{23}H_{18}N_2$ *i.e.* $C_{10}H_7.C(NPh).NHPh$. [183·5°]. Formed from (α)-naphthoic acid, aniline, and PCl_3 (Bössneck, *B.* 16, 642). Needles (from alcohol).

PHENYL-(β)-NAPHTHINDOLE $C_{18}H_{13}N$ *i.e.* $C_{10}H_6<\begin{matrix}CH\\NH\end{matrix}>CPh$. [130°]. Formed by heating the (β)-naphthyl-hydrazide of acetophenone with $ZnCl_2$ at 170° (Ince, *A.* 253, 42). Crystals, v. sol. alcohol and ether. Colours pinewood green.—$B'C_6H_3N_3O_7$. [166°]. Brown needles.

Phenyl-(β)-naphthindole $C_{10}H_6<\begin{matrix}CPh\\NH\end{matrix}>CH$. [211°]. Formed by the action of alcoholic HCl on the (β)-naphthyl-hydrazide of phenyl-acetic aldehyde (I.). Needles, suddenly decomposed on fusion. Colours pinewood green. $ZnCl_2$ at 170° converts it into the preceding isomeride.—$B'C_6H_3N_3O_7$. [120°]. Reddish-brown needles.

PHENYL-NAPHTHOTRIAZINE. *Dihydride* $C_{17}H_{13}N_3$ *i.e.* $C_{10}H_6<\begin{matrix}N.CH_2\\N.NPh\end{matrix}$. [184°]. Formed by heating benzene-azo-(β)-naphthylamine with formic paraldehyde at 140° (Goldschmidt a. Poltzer, *B.* 24, 1002). Plates (containing $\frac{2}{3}$ aq).—B'HCl. [254°].—$B'_2H_2PtCl_6$.

Di-phenyl-(αβ)-naphthotriazine $C_{23}H_{17}N_3$ *i.e.* $C_{10}H_6<\begin{matrix}N.CHPh\\N.NPh\end{matrix}$? [194°]. Got by heating a solution of $CHPh{:}N.C_{10}H_6.N_2Ph$ in HOAc (Meldola, *C. J.* 57, 330). White flattened needles.

PHENYL-NAPHTHOPHENANTHRAZINE

$\begin{matrix}C_6H_4.CH.N\\C_6H_4.CH.N\end{matrix}>C_{10}H_6$. The *phenylo-nitrate* $B'PhNO_3$, formed by boiling phenanthraquinone with phenyl-naphthylene-diamine in HOAc and then adding HNO_3 crystallises in dichroic needles or prisms (Witt, *B.* 20, 1185).

(*Py.* 3)-**PHENYL-(α)-NAPHTHOQUINOLINE** $C_{19}H_{13}N$ *i.e.* $C_{10}H_6<\begin{matrix}CH{:}CH\\N{=}CPh\end{matrix}$. [68°]. Formed by heating its (*Py.* 1)-carboxylic acid with soda-lime (Döbner, *A.* 249, 114). Yellow needles (from alcohol-ether). Yields a syrupy tetrahydride. *Salts.*—$B'_2H_2PtCl_6$ 2aq.—$B'H_2Cr_2O_7$.—$B'C_6H_3N_3O_7$. [167°]. Thin needles (from alcohol).

(*Py.* 3)-**Phenyl-(β)-naphthoquinoline.** [188°]. Formed by heating its carboxylic acid with soda-lime (D.). Needles or plates, insol. water, v. sol. alcohol.—$B'_2H_2PtCl_6$ aq.—$B'C_6H_3N_3O_7$. [250°]. Yellow plates, sl. sol. ether.—$B'_2H_2Cr_2O_7$.

Ethylo-iodide. [233°]. Plates, insol. ether.

(*Py.* 3)-**PHENYL-(α)-NAPHTHOQUINOLINE** (*Py.* 1)-**CARBOXYLIC ACID** $C_{20}H_{13}NO_2$ *i.e.* $C_{10}H_6<\begin{matrix}C(CO_2H){:}CH\\N{=\!=\!=}CPh\end{matrix}$. [300°]. Formed by heating (α)-naphthylamine with pyruvic acid and benzoic aldehyde in alcoholic solution (D.). Yellow needles (from alcohol-acetone). May be reduced to a tetrahydride. Produces, on oxidation, di-phenyl-pyridine tri-carboxylic acid and $CO_2H.C_5NHPh<\begin{matrix}C_6H_4\\CO\end{matrix}$.—NaA' $\frac{1}{2}$aq.—CaA'_2 4aq.—ZnA'_2.—PbA'_2.—AgA': insoluble powder.

Ethyl ether EtA'. [103°]. Needles.

(*Py.* 3)-**Phenyl-(β)-naphthoquinoline** (*Py.* 1)-**carboxylic acid** $C_{20}H_{13}NO_2$. [296°]. Formed in like manner from (β)-naphthylamine (D.). Needles, v. sl. sol. alcohol.—KA' 5aq.—NaA' 5aq.—CaA'_2 6aq.—ZnA'_2 2aq.—$Cu_2A'_3$ aq (?).—AgA'.

PHENYL-NAPHTHOQUINOXALINE

$C_{10}H_6<\begin{matrix}N{:}CH\\N{:}CPh\end{matrix}$. The *phenylo-bromide* B'PhBr, formed from phenyl-naphthylene-diamine and bromo-acetophenone, crystallises in yellow plates, and is converted by NaOH into B'PhOH [148°], which crystallises in prisms, and yields $B'PhNO_3$ (Fischer a. Busch, *B.* 24, 1873).

Di-phenyl-naphthoquinoxaline

$C_{10}H_6<\begin{matrix}N{:}CPh\\N{:}CPh\end{matrix}$. [147°]. Formed by heating naphthylene-(1,2)-diamine hydrochloride with benzil in alcohol (Lawson, *B.* 18, 2426). Light-brown plates, v. sol. alcohol and ether.

Phenylo-hydroxide

$C_{10}H_6<\begin{matrix}N{=\!=\!=\!=}CPh\\NPh(OH){:}CPh\end{matrix}$. [167°]. Formed by oxidation of $C_{10}H_6<\begin{matrix}N{=\!=}CPh\\NPh.CHPh\end{matrix}$ [164°], which is got by heating phenyl-naphthylene-*o*-diamine with benzoïn at 200° (Fischer, *B.* 24, 722, 1871). Formed also from naphthylene-phenyl-diamine and benzil (Fischer, *B.* 24, 2679). Yellow prisms, insol. water, v. sol. ether.—$B'HNO_3$.—$B'HCl$: dark-yellow needles, v. sol. alcohol.

Di-phenyl-naphthoquinoxaline dihydride  $C_{10}H_6<\begin{matrix}NPh.CH_2\\ N \text{ — } CPh\end{matrix}$. [165°]. Formed, together with a compound melting at 195°, from naphthylene-phenyl-diamine and benzoyl-carbinol at 155° (Fischer a. Busch, *B.* 24, 2680). Orange needles, v. sol. benzene, v. sl. sol. alcohol.

PHENYL-NAPHTHOROSINDULINE  $C_6H_4<\begin{matrix}\text{————}C{:}N\text{—}C{:}CH\\ C(NPh).CH{:}C.NPh.C{:}CH\end{matrix}>C_6H_4$. [2[illegible]°]. Formed, together with naphthyl-rosinduline, from benzene-azo-di-(α)-naphthylamine, hydrochloride, aniline, and alcohol at 165° (Fischer a. Hepp, *A.* 256, 247). Deep-red bronzed plates. Conc. HClAq forms aniline and naphthorosindone [295°].

DI-PHENYL-(α)-NAPHTHYL-ACETAMIDINE $C_{10}H_7.CH_2.C(NPh).NHPh$. [130°]. Formed from (α)-naphthyl-acetic acid (3 mols.), aniline (6 mols.), and PCl_3 (Boessneck, *B.* 16, 642). Needles, sol. ether and benzene.

PHENYL-(α)-NAPHTHYL-AMINE $C_{16}H_{13}N$ *i.e.* $C_6H_5.NH.C_{10}H_7$. [60°]. Forms by heating (α)-naphthylamine hydrochloride with aniline at 250° (Girard a. Vogt, *Bl.* [2] 18, 67; Streiff, *B.* 13, 1852). Prepared by heating a mixture of (α)-naphthol (15 pts.), aniline (19·4 pts.) and $CaCl_2$ (11·6 pts.) under pressure for 9 hours at 280°; the yield being 26 p.c. of the theoretical (Friedländer, *B.* 16, 2077). White plates or prisms, v. sol. alcohol. Its solutions show blue fluorescence. Yields a tri-bromo- derivative [137°] and a di-nitro- derivative [77°]. H_2SO_4 at 100° forms a tetra-sulphonic acid.—$B'HCl$: prisms, decomposed by water.—$B'C_6H_3N_3O_7$.

Acetyl derivative $C_{18}H_{15}NO$. [115°].

Benzoyl derivative. [152°].

Nitrosamine. $C_{10}H_7.NPh.NO$. [92°]. Reddish-yellow crystals (Fischer a. Hepp, *B.* 20, 1247).

Phenyl-(β)-naphthylamine $C_{16}H_{13}N$. [108°]. (395°). Formed by heating (β)-naphthol with aniline and $ZnCl_2$ at 190° (Merz a. Weith, *B.* 13, 1300), or with aniline hydrochloride (Merz a. Weith, *B.* 13, 1850).

Preparation.—A mixture of (β)-naphthol (15 pts.), aniline (19·4 pts.), and $CaCl_2$ (11·6 pts.) is heated under pressure at 280° for 9 hours; the yield is 98 p.c. of the theoretical (Friedländer, *B.* 16, 2075).

Properties.—White needles, sol. MeOH. Yields a tetra-bromo- derivative [198°] and a nitro- derivative [87°]. With nitroso-di-methyl-aniline hydrochloride and HOAc it yields lustrous black crystals, which form a violet solution in H_2SO_4 (Witt, *B.* 21, 723). Sulphur at 240° forms  $S<\begin{matrix}C_{10}H_6\\ C_6H_4\end{matrix}>NH$ [178°] (Kym, *B.* 23, 2466). H_2SO_4 at 100° forms a trisulphonic acid

Salts.—$B'HCl$: unstable crystalline powder. —$B'C_6H_3N_3O_7$. Brownish needles, v. sol. $CHCl_3$.

Acetyl derivative. [93°]. Crystals.

Benzoyl derivative. [136°] (Streiff, *A.* 209, 151); [148°] (Claus a. Richter, *B.* 17, 1591).

Nitrosamine $C_{10}H_7.NPh.NO$. [93°].

Di-phenyl-naphthylamine $C_{10}H_7NPh_2$. [142°]. (335°–340° at 85 mm.). Formed by adding α-bromo-naphthalene (20 g.) to a boiling solution of potassium (3·3 g.) in diphenylamine (20 g.) mixed with aniline (15 c.c.) (Herz, *B.* 23, 2541). Silky needles (from dilute alcohol), insol. water.

References.—Nitro-amido-, Di-nitro-, and Nitroso- Phenyl-naphthyl-amine.

PHENYL-(α)-NAPHTHYLAMINE BLUE *v.* Tri-naphthyl-tri-amido-tri-phenyl-carbinyl chloride.

PHENYL-(β)-NAPHTHYL-CARBAMIC ACID.

Ethyl ether $C_{10}H_7NPh.CO_2Et$. [93°]. Formed by the action of NaOEt on the chloride (Paschkowezky, *B.* 24, 2919). Satiny needles.

Phenyl ether $C_{10}H_7NPh.CO_2Ph$. [149°]. S. (96 p.c. alcohol) ·36 at 17°; S. (benzene) 2·3 at 17°. Formed from the chloride and NaOPh. Needles, v. sl. sol. cold alcohol.

Chloride $C_{10}H_7NPh.COCl$. [102°]. Formed from phenyl-(β)-naphthylamine and $COCl_2$ in toluene (Kym, *B.* 23, 425). White plates.

PHENYL-(α)-NAPHTHYL CARBINOL $Ph.CH(OH).C_{10}H_7$. [86·5°]. (above 360°). Formed from the ketone, zinc-dust, and KOH (Elbs, *J. pr.* [2] 35, 504; *cf.* Lehne, *B.* 13, 359; Beckmann, *B.* 22, 915). Crystals, v. sol. alcohol. Gives a violet colour with H_2SO_4.

Phenyl-di-(α)-naphthyl carbinol $C_{27}H_{20}O$ *i.e.* $Ph.C(C_{10}H_7)_2OH$. [160°–170°]. Formed, together with benzoic aldehyde, by boiling phenyl-(α)-naphthyl-(β)-pinacolin $(C_{10}H_7)_2CPhBz$ (got by reducing phenyl (α)-naphthyl ketone with zinc and alcoholic HCl) with alcoholic KOH (Elbs, *J. pr.* [2] 35, 507). Grey crystalline crusts (from ether-alcohol), m. sol. alcohol, v. sol. ether.

PHENYL-(β)-NAPHTHYL-CARBINYL-THIO-UREA. *Tetrahydride* $C_{18}H_{20}N_2S$ *i.e.* $NHPh.CS.NH.CH_2C_{10}H_{11}$. [140°]. Formed from $C_{10}H_{11}.CH_2NH_2$ and phenyl thiocarbimide (Bamberger a. Helwig, *B.* 22, 1913). Vitreous rosettes.

PHENYL-NAPHTHYL-CARBINYL-UREA. *Tetrahydride* $NHPh.CO.NH.CH_2C_{10}H_{11}$. Formed from naphthyl-carbinylamine and phenyl cyanate (Bamberger, *B.* 22, 1913). The (α)-compound melts at 126·5°, the (β)-isomeride at 141°. Both crystallise in needles.

PHENYL-(α)-NAPHTHYLENE-DIAMINE $C_{16}H_{14}N_2$ *i.e.* $C_{10}H_6(NH_2)(NHPh)$ [1:4]. [148°]. Formed by reducing nitroso-phenyl-(α)-naphthylamine (Wacker, *A.* 243, 305). Needles (from alcohol) or plates (from benzene).

Phenyl-*o*-naphthylene-diamine $C_{10}H_6(NH_2)(NHC_6H_5)$ [1:2]. *Amido-(β)-naphthyl-phenyl-amine.* [140°]. Formed, together with aniline, by reduction of benzene-azo-(β) naphthyl-phenyl-amine with $SnCl_2$ (Zincke a. Lawson, *B.* 20, 1170; Witt, *B.* 20, 1184). Broad needles or plates. Nitrous acid passed into HOAc (11 pts.) containing the hydrochloride in suspension forms $C_{16}H_8N_4O_2$ or $C_{16}H_{10}N_4O_2$ [208°], whence $SnCl_2$ forms $C_{16}H_{12}N_4$ [194°], which yields $B'HCl$, $C_{16}H_{11}AcN_4$ [261°] and $C_{16}H_{10}Ac_2N_4$ [177°], and gives with benzoic aldehyde a compound $C_{23}H_{16}N_4$ [15[illegible]°] (Zincke a. Campbell, *A.* 255, 349).

Salts.—$B'HCl$: long colourless glistening needles, v. sl. sol. water, more readily in alcohol. —$^{\times}B'H_2SO_4$: needles, similar solubility.

Phenyl-dinaphthylene-amine $C_{26}H_{17}N$ *i.e.*  $\begin{matrix}C_{10}H_6\\ C_{10}H_6\end{matrix}>NPh$. [c. 144°]. Formed by heating (ββ)-di-oxy-dinaphthyl with aniline-zinc-chloride.

at 300° (Walder, *B.* 15, 2175). Prisms or needles, sol. alcohol.—$B'2C_6H_3N_3O_7$. [169°].

Di-phenyl-naphthylene-diamine [2:2′] $C_{10}H_6(NHPh)_2$. [168°]. Formed, together with $C_{10}H_6(OH)(NHPh)$ [163°], by heating dioxy-naphthalene with aniline and $CaCl_2$ (Annaheim, *B.* 20, 1372; Clausius, *B.* 23, 528). Silvery plates (from hot benzene).

Acetyl derivative $C_{26}H_{22}N_2O_3$. [198°].

Di-phenyl-naphthylene-*p*-diamine [1:4] $C_{10}H_6(NHPh)_2$. [144°]. Formed by reducing the di-anilide of (*α*)-naphthoquinone with zinc, HOAc, and alcohol (Fischer a. Hepp, *A.* 256, 255). Colourless prisms.

DI-PHENYL-NAPHTHYLENE-DI-THIO-UREA $C_{10}H_6(NH.CS.NHPh)_2$. [355°–360°]. Formed from naphthylene (1,2)-diamine and phenyl-thio-carbimide (Bamberger a. Schieffelin, *B.* 22, 1376). Needles.

DI-PHENYL-NAPHTHYLENE-UREA $C_{10}H_6(NH.CO.NHPh)_2$. [335°]. Formed from naphthylene (1,2)-diamine and phenyl cyanate (Bamberger a. Schieffelin, *B.* 22, 1376). Crystalline granules, v. sl. sol. benzene.

PHENYL-NAPHTHYL-ETHANE $C_{18}H_{16}$ *i.e.* $C_{10}H_7.CH_2.CH_2Ph$. Formed by heating naphthyl benzyl ketone with HI and P at 155° (Graebe a. Bungener, *B.* 12, 1078). Yields chrysene on passing through a red-hot tube.

***s*-PHENYL-(*β*)-NAPHTHYL-ETHYLENE** $C_6H_5.C_2H_2.C_{10}H_7$. [145°]. Formed by distilling (*β*)-naphthyl cinnamate, CO_2 being split off (Anschütz, *B.* 18, 1946). Silvery plates.

Di-bromide. [192°].

PHENYL-NAPHTHYL-ETHYLENE-*ψ*-THIO-UREA $NPh:C<\begin{matrix}N(C_{10}H_7)\\S.CH_2\end{matrix}>CH_2$. [185°]. Formed from phenyl-(*α*)-naphthyl-urea and ethylene bromide (Foerster, *B.* 21, 1870).

DI-PHENYL-NAPHTHYL-GUANIDINE $C_{23}H_{19}N_3$ i.e. $CN_3H_2Ph_2(C_{10}H_7)$. [155°]. Formed by heating di-phenyl-thio-urea with (*α*)-naphthylamine, alcohol, and PbO (Tiemann, *B.* 3, 6; *Z.* [2] 6, 309). Crystalline, sol. alcohol.

PHENYL-(*β*)-NAPHTHYL-GUANIDINE CARBOXYLIC ACID $C_{10}H_7NH.C(NH).NH.C_6H_4.CO_2H$. Formed by heating cyan-carbimidamido-benzoic acid with (*β*)-naphthylamine (Griess, *B.* 16, 338). Crystals sl. sol. hot alcohol.—B′HCl. Six-sided plates.

PHENYL (*α*)-NAPHTHYL-KETONE $C_{17}H_{12}O$ *i.e.* $C_6H_5.CO.C_{10}H_7$. Mol. w. 232. [75·5°]. (385°) (Schweizer, *A.* 261, 196). V.D. 119 (calc. 116). S. (alcohol) 2·5 at 12°.

Formation. — 1. Together with the (*β*)-isomeride, by heating naphthalene with HOBz and P_2O_5 at 210° (Merz, *B.* 6, 541, 966, 1238).—2. By heating (*α*)-naphthoic acid with benzene and P_2O_5 (M.).—3. Together with a smaller quantity of the (*β*)- isomeride, by the action of $AlCl_3$ on a mixture of naphthalene, CS_2, and BzCl. The two ketones are separated by crystallisation from alcohol-ether (Elbs, *J. pr.* [2] 35, 503; *B.* 19, 1965; Rospendowski, *C. R.* 102, 872).—4. By heating naphthalene with BzCl and $ZnCl_2$, or Zn (Roux, *A. Ch.* [6] 12, 338; Kegel, *A.* 247, 178).

Properties.—Trimetric prisms, very slightly volatile with steam.

Reactions.—1. Br forms $C_{17}H_{11}BrO$ [98°] (E.); [100·5°] (Rospendowski), whence HNO_3 gives $C_{17}H_9Br(NO_2)_2O$ decomposing at 90°.—2. Conc. H_2SO_4 with a few drops of water forms at 100°–150° benzoic acid and naphthalene (*β*)-sulphonic acid.—3. *Soda-lime* at 350° forms naphthalene and NaOBz.—4. *Chromic acid mixture* forms $C_6H_5.CO.C_6H_3(CO_2H)_2$[1:2:3]. [155°].—5. *Sodium* acting on its ethereal solution forms a greenish-yellow compound $(C_{10}H_7.CPh)_2O_2Na_2$, whence water produces $CPh(C_{10}H_7)_2.CO.C_6H_5$ and other bodies, while CO_2 acting on the Na compound forms a yellow powder, split up by water into ketone and $C_6H_5.C(C_{10}H_7)(OH).CO_2H$ [148°] (Beckmann a. Paul, *A.* 266, 10).

Oxim $C_6H_5.C(NOH).C_{10}H_7$. [142°]. Groups of white needles (from dilute alcohol) (Kegel, *A.* 247, 181). Oxidised by CrO_3 in HOAc to $C_6H_5.CO.C_6H_3<\begin{matrix}CO.CH\\CO.CH\end{matrix}$ [152°], which yields an anilide $C_6H_3Bz<\begin{matrix}CO.C.NHPh\\CO.CH\end{matrix}$ [200°] and a *p*-toluide [197°] both converted by boiling NaOHAq into $C_6H_3Bz<\begin{matrix}CO.C.OH\\CO.CH\end{matrix}$ [222°].

Phenyl (*β*)-naphthyl ketone [82°]. S. 2 at 12°. Formed, at the same time as the (*α*)- isomeride, from naphthalene (*v. supra*). Formed also by heating (*β*)-naphthoic acid with benzene and P_2O_5 (Merz). Needles, v. sol. hot alcohol.

Oxim. [176°]. Needles. Oxidised by CrO_3 in HOAc to yellow $C_6H_3Bz<\begin{matrix}CO.CH\\CO.CH\end{matrix}$ [132°], which is converted by heating with aniline into dark-red plates of $C_6H_3Bz<\begin{matrix}CO.C.NHPh\\CO.CH\end{matrix}$ [210°].

Reference. — DI-OXY-PHENYL-NAPHTHYL-KETONE.

PHENYL NAPHTHYL KETONE *o*-CARBOXYLIC ACID $C_{10}H_7.CO.C_6H_4.CO_2H$. [174°]. The chloride is formed from naphthalene, phthalic anhydride, and $AlCl_3$ (Ador a. Crafts, *Bl.* [2] 31, 531). Prisms (from dilute alcohol).

PHENYL-NAPHTHYL-METHANE *v.* BENZYL-NAPHTHALENE.

Phenyl-di-(*α*)-naphthyl-methane $C_{27}H_{20}$ *i.e.* $C_6H_5CH(C_{10}H_7)_2$. [c. 180°]. Formed from phenyl-(*α*) naphthyl-(*β*)-pinacolin by distilling with zinc-dust. Got also by heating phenyl-di-(*α*)-naphthyl-carbinol with zinc-dust (Elbs, *J. pr.* [2] 35, 508). Grey powder; cakes together at 100°.

Di-phenyl-naphthyl-methane $C_{10}H_7.CHPh_2$. [134° and 149°]. Formed by heating di-phenyl-carbinol with naphthalene and P_2O_5 at 140° (Lehne, *B.* 13, 358; Hemilian, *Bl.* [2] 34, 326). Needles, sol. benzene and ether, sl. sol. alcohol.

PHENYL-(*α*)-NAPHTHYL-METHYL-PYRROLE $\begin{matrix}CH:CPh\\CH:CMe\end{matrix}>NC_{10}H_7$. [74°]. (above 360°). Formed by heating the carboxylic acid [244°] (Lederer a. Paal, *B.* 18, 2598). Plates. V. e. sol. alcohol, benzene, and ligroin.

Phenyl-(*β*)-naphthyl-methyl-pyrrole $\begin{matrix}CH:CPh\\CH:CMe\end{matrix}>NC_{10}H_7$. [52°]. Formed by heating the carboxylic acid [249°] (L. a. P.). Small white concentric needles. V. sol. alcohol.

PHENYL-(*α*)-NAPHTHYL-METHYL-PYRROLE CARBOXYLIC ACID $\begin{matrix}CH:CPh\\CO_2H.C{=}CMe\end{matrix}>NC_{10}H_7$. [244°]. Formed by

heating acetophenoneacetoacetic ether with (α)-naphthylamine at 130°, and saponification of the product (Lederer a. Paal, *B.* 18, 2598). Needles. V. sol. alcohol, benzene, and acetic acid.

Phenyl-β-naphthyl-methyl-pyrrole carboxylic acid. [249°]. Formed in like manner, using (β)-naphthylamine (L. a. P.). Small white needles, sol. alcohol and HOAc.

Ethyl ether EtA′. [115°]. Plates.

PHENYL-(β)-NAPHTHYL-METHYL-THIO-UREA $C_{10}H_7NH.CS.NPhMe$. [127°]. Got from (β)-naphthyl-thiocarbimide and methyl-aniline (Gebhardt, *B.* 17, 2091). Long yellow needles.

Phenyl-(α)-naphthyl-methyl-ψ-thio-urea $C_{10}H_7N{:}C(SMe).NHPh$. [96°]. Formed from phenyl (α)-naphthyl-thio-urea and MeI (Foerster, *B.* 21, 1870). Small white needles. Yields (α)-naphthyl-thiocarbimide on heating with CS_2.

PHENYL-(α)-NAPHTHYL-(β)-PINACOLIN $C_6H_5.C(C_{10}H_7)_2.CO.C_6H_5$. [c. 130°]. From phenyl-(α)-naphthyl ketone by boiling with zinc and HCl (Elbs, *J. pr.* [2] 35, 505). Pale greenish-yellow crystalline crusts, v. sol. ether, sl. sol. alcohol, insol. water. Cakes together at 100°–110°. Boiling alcoholic KOH forms benzoic aldehyde and phenyl-di-naphthyl-carbinol.

PHENYL-(α)-NAPHTHYL-PINACONE $C_{10}H_7CPh(OH).CPh(OH).C_{10}H_7$. [61°]. A product of the action of sodium-amalgam on an alcoholic solution of phenyl-(α)-naphthyl ketone (Lehne, *B.* 13, 1360). Needles (from ether).

DI-PHENYL-(α)-NAPHTHYL-PYRROLE  $\begin{matrix}CH{:}CPh\\CH{:}CPh\end{matrix}{>}NC_{10}H_7$. [149°]. Formed by heating its carboxylic acid with lime (Paal a. Braikoff, *B.* 22, 3092). Needles, v. sol. hot alcohol.

Di-phenyl-(β)-naphthyl-pyrrole. [208°]. Formed in like manner (P. a. B.). Needles.

DI-PHENYL-(α)-NAPHTHYL-PYRROLE CARBOXYLIC ACID  $\begin{matrix}CO_2H.C{=}CPh\\CH{:}CPh\end{matrix}{>}NC_{10}H_7$. [272°]. Got by saponifying its ether, which is obtained from phenacyl-benzoyl-acetic ether and (α)-naphthylamine (Paal a. Braikoff, *B.* 22, 3091). Small white plates, sl. sol. hot alcohol.—KA′. Sl. sol. hot water.

Ethyl ether EtA′. [182°]. Needles.

Di-phenyl-(β)-naphthyl-pyrrole carboxylic acid. [above 350°]. Got in like manner, using (β)-naphthylamine. Plates.—KA′. Sl. sol. water.

Ethyl ether EtA′. [182°]. Needles.

PHENYL-(α)-NAPHTHYL SULPHIDE $C_{10}H_7.SPh$. [42°] (K. a. B.); [49°]. (c. 215° at 15 mm.). Formed from $Pb(SPh)_2$ and $C_{10}H_7Br$ (Krafft a. Bourgeois, *B.* 23, 3047). Formed also from (α)-diazonaphthalene chloride and NaSPh (Ziegler, *B.* 23, 2471). Prisms (from dil. alcohol).

Phenyl (β)-naphthyl sulphide. [52°]. (c. 221° at 14 mm.). Formed in like manner. Needles.

PHENYL (α)-NAPHTHYL SULPHONE $C_6H_5.SO_2.C_{10}H_7$. [100°]. Formed by oxidising phenyl (α)-naphthyl sulphide with CrO_3 and HOAc (Krafft a. Bourgeois, *B.* 23, 3047). Formed also, together with the (β)-isomeride, by heating benzene sulphonic acid with naphthalene and P_2O_5 at 175° (Michael a. Adair, *B.* 10, 585). Crystals (from alcohol).

Phenyl (β)-naphthyl sulphone. [116°]. Formed in like manner, and also by heating naphthalene (β)-sulphonic acid with benzene and P_2O_5 (M. a. A.), and by the action of zinc-dust or $AlCl_3$ on a mixture of naphthalene and benzene sulphonic chloride (Crustschoff, *B.* 7, 1167; Otto a. Beckurts, *B.* 11, 2069). Needles.

PHENYL-(α)-NAPHTHYL-THIO-SEMICARBAZIDE $NHPh.CS.NH.NHC_{10}H_7$. [135°]. Formed from (α)-naphthyl-hydrazine and phenyl-thio-carbimide (Freund, *B.* 24, 4191). Needles.

Phenyl-(β)-naphthyl-thio-semicarbazide. [202°]. Formed in like manner from (β)-naphthyl-hydrazine (F.). White plates.

PHENYL-(α)-NAPHTHYL-THIO-UREA $NHPh.CS.NHC_{10}H_7$. [163°]. Formed from (α)-naphthylamine and phenyl-thiocarbimide (Hofmann, *Pr.* 9, 274), and also from aniline and (α)-naphthyl-thiocarbimide (Mainzer, *B.* 15, 1414). Plates, v. sl. sol. alcohol. With ethylene bromide it gives two bases [185°] and [130°].

Tetrahydride $NHPh.CS.NHC_{10}H_{11}$. [153°]. Formed from phenyl-thiocarbimide and (α)-naphthylamine tetrahydride (Bamberger, *B.* 21, 1794). Prisms, v. sol. benzene-alcohol.

Phenyl-(β)-naphthyl-thio-urea $NHPh.CS.NHC_{10}H_7$. [165°]. Formed from (β)-naphthylamine and phenyl thiocarbimide (M.; Freund a. Wolf, *B.* 25, 1468). Plates. Split up by HClAq at 150° into aniline, (β)-naphthylamine, and phenyl and (β)-naphthyl thiocarbimides. $COCl_2$ in toluene forms $NPh{:}C{<}\begin{matrix}NC_{10}H_6\\S\end{matrix}{>}CO$ [117°].

Tetrahydride $NHPh.CS.NHC_{10}H_{11}$. [161°]. Formed from phenyl thiocarbimide and (β)-naphthylamine tetrahydride (Bamberger a. Müller, *B.* 21, 858). Prisms (from alcohol).

PHENYL-(α)-NAPHTHYL-UREA. *Tetrahydride* $NHPh.CO.NHC_{10}H_{11}$. [193°]. Formed from (α)-naphthylamine tetrahydride and phenyl cyanate (Bamberger, *B.* 21, 1794). Needles.

u-Phenyl-(β)-naphthyl-urea $NH_2.CO.NPh.C_{10}H_7$. [190°]. Formed by heating $NPh(C_{10}H_7).COCl$ and alcoholic NH_3 at 130° (Kym, *B.* 23, 426). Needles, sl. sol. cold alcohol.

Phenyl-(β)-naphthyl-urea $NHPh.CO.NHC_{10}H_7$. [221°]. Formed from phenyl cyanate and (β)-naphthylamine (Goldschmidt, *B.* 21, 2567). Prisms (from alcohol).

Tetrahydride $NHPh.CO.NHC_{10}H_{11}$. [166°]. Formed from phenyl cyanate and the tetrahydride of (β)-naphthylamine (Bamberger a. Müller, *B.* 21, 859). Needles, v. e. sol. alcohol.

Phenyl-di-(β)-naphthyl-urea $C_{27}H_{20}N_2O$ *i.e.* $NHPh.CO.N(C_{10}H_7)_2$. [182°]. Formed from phenyl cyanate and di-(β)-naphthylamine (Gebhardt, *B.* 17, 3039). Formed also by heating $N(C_{10}H_7)_2.COCl$ with aniline in $CHCl_3$ at 130° (Kym, *B.* 23, 429; Kühn a. Landau, *B.* 23, 811). Needles (from alcohol). By heating with aniline it is converted into $CO(NHPh)_2$ and di-(β)-naphthylamine.

Phenyl-tri-(β)-naphthyl-urea $CO(NPhC_{10}H_7).N(C_{10}H_7)_2$. [168°]. S. (alcohol) ·9 at 16°; S. (benzene) 4·54 at 16°. Formed from $(C_{10}H_7)_2N.COCl$ and phenyl-(β)-naphthylamine at 260° (Paschkowezky, *B.* 24, 2924). Granular crystals, sl. sol. cold alcohol.

Di-phenyl-(β)-naphthyl-urea $NHPh.CO.NPhC_{10}H_7$. [133°]. Formed from $NPh(C_{10}H_7).COCl$ and aniline (Kym, *B.* 23, 426). White plates, sl. sol. cold alcohol.

u-Di-phenyl-di-(β)-naphthyl-urea $NPh_2.CO.N(C_{10}H_7)_2$. [104°]. Formed by heating $NPh_2.COCl$ with $(C_{10}H_7)_2NH$ at 220° or by heating $(C_{10}H_7)_2N.COCl$ with NPh_2H at 260° (Paschkowezky, *B.* 24, 2923). Crystalline powder, m. sol. cold alcohol.

s-Di-phenyl-di-(β)-naphthyl-urea $CO(NPh.C_{10}H_7)_2$. [186°]. S. (alcohol) 1 at 18·5°. S. (benzene) 59 at 18·5°. Formed by heating $C_{10}H_7NPh.COCl$ with $C_{10}H_7NPh.COCl$ at 250° (P.). Polyhedral granules. Converted by HClAq at 250° into aniline, (β)-naphthol, and CO_2.

Tri-phenyl-(β)-naphthyl-urea $NPh_2.CO.NPh.(C_{10}H_7)$. [128°]. Formed from $C_{10}H_7NPh.COCl$ and NPh_2H at 240° (P.). Crystalline powder, v. sol. alcohol.

PHENYL *o*-NITRO-BENZYL KETONE $C_6H_5.CO.CH_2.C_6H_4NO_2$. *Nitro-deoxybenzoïn.* Formed, together with the *p*-isomeride, by nitrating phenyl benzyl ketone (Ney, *B.* 21, 2448). Sol. ether (difference from *p*-isomeride). The *p*-isomeride yields a crystalline oxim [107°].

PHENYL *p*-NITRO-BENZYL OXIDE $C_6H_5.O.CH_2.C_6H_4NO_2$. [91°]. Formed from *p*-nitro-benzyl chloride and KOPh (Kumpf, *B.* 17, 1076). Plates (from alcohol).

Reference.—NITRO-PHENYL-NITRO-BENZYL OXIDE.

PHENYL NITRODIPHENYLETHYL KETONE $C_6H_5.CO.CHPh.CH_2.C_6H_4NO_2$. Formed from nitro-benzyl chloride, deoxybenzoïn, and NaOEt (Buddeberg, *B.* 23, 2071). The *o*-compound melts at 102° and yields diphenylquinoline [96°] (420°) on reduction. The *p*-isomeride melts at 112° and yields an amido-compound [141°] on reduction.

DI-PHENYL-DINITROSACYL. So-called. $C_{16}H_{10}N_2O_4$. [87°]. The chief product of the action of HNO_3 (S. G. 1·4) on acetophenone (Hollemann, *B.* 21, 860, 2835). It is accompanied by an isomeride [179°]. Crystals (from ether). Converted by acids and alkalis into benzoic and oxalic acids, NH_3, and hydroxylamine. Ac_2O yields $C_{16}H_{10}Ac_2N_2O_5$ [149°]. Aniline and benzanilide form compounds melting at 205° and 160° respectively.

DI-PHENYL-NITROSAMINE *v. Nitrosamine* of DI-PHENYL-AMINE.

PHENYL-NITRO-TOLYL-THIO-UREA *v.* NITRO-PHENYL-TOLYL-THIO-UREA.

DI-PHENYL-NITRO-*p*-TOLYL-UREA $NPh_2.CO.NHC_6H_3Me(NO_2)$ [1:4:3]. [139·5°]. Formed from nitro-*p*-toluidine and $NPh_2.COCl$ at 125° (Lellmann a. Bonhöffer, *B.* 20, 2121). Yellow needles, v. sol. chloroform and benzene.

PHENYL-OCTINOIC ACID $C_{14}H_{16}O_2$ *i.e.* $PhC(C_2H_3)(C_2H_2Et).CO_2H$ (310°–320°). This appears to be one of the products of the action of CO at 170° on a mixture of NaOEt and $PhCH_2.CO_2Na$ (M. Schroeder, *A.* 221, 46).

PHENYL-OCTOIC ACID. *Nitrile.* $C_6H_{13}.CHPh.CN$. (287°). Formed from phenyl-acetonitrile, hexyl iodide, and NaOH (Rossolymo, *B.* 22, 1237). Oil.

DI-PHENYL-*n*-OCTYL TRICYANIDE $C_8H_{17}.C_3N_3Ph_2$. [43°]. (285° at 15 mm.). Formed from $C_8H_{17}.COCl$, benzonitrile, and $AlCl_3$ (Krafft a. Koenig, *B.* 23, 2384).

PHENYL-OCTYL-THIO-UREA $C_{15}H_{24}N_2S$ *i.e.* $C_8H_{17}NH.CS.NHPh$. [53°]. Formed from aniline and *sec*-octyl-thiocarbimide (Jahn, *B.* 8, 804).

ν-PHENYL-OSOTRIAZOLE $C_8H_7N_3$ *i.e.*  $\left.\begin{array}{l}CH{:}N\\CH{:}N\end{array}\right>NPh$. [224°]. Formed by warming the osotetrazone of glyoxal with $FeCl_3$ and HClAq (Pechmann, *A.* 262, 291). Sl. sol. water, v. sol. alcohol. HNO_3 yields  $\left.\begin{array}{l}C(NO_2){:}N\\CH{=\!=}N\end{array}\right>NPh$ [184°].

Tri-phenyl-osotriazole  $\left.\begin{array}{l}CPh{:}N\\CPh{:}N\end{array}\right>NPh$. [122°]. Formed by heating the diphenyl-dihydrazide of benzil with alcohol at 210° (Auwers a. V. Meyer, *B.* 21, 2806). White plates.

PHENYL-OSOTRIAZOLE CARBOXYLIC ACID  $\left.\begin{array}{r}CO_2H.C{=}N\\CH{:}N\end{array}\right>NPh$. [192°]. Formed by oxidising phenyl-methyl-osotriazole with $KMnO_4$ (Von Pechmann, *B.* 21, 2760). Formed also by boiling the phenyl-hydrazide of di-nitroso-acetone with NaOHAq (Pechmann, *A.* 262, 283). White needles, sol. alcohol, not volatile with steam. Yields a nitro-compound [236°] which may be reduced to an amido-compound [252°].

Salts.—KA' aq.—BaA'_2 4aq.—CdA'_2 4aq.

Methyl ether MeA'. [90°]. (286°).

Ethyl ether EtA'. [59°]. (306°).

Amide $C_2N_3HPh.CONH_2$. [143·5°]. Formed by boiling the phenyl-hydrazide of acetyl-di-nitroso-acetone with Na_2CO_3Aq (P.). Needles.

Nitrile $C_2HN_3Ph.CN$. [94·5°]. (191° at 60 mm.). Formed by the action of NaOH on the phenyl-hydrazide of di-nitroso-acetone (Pechmann, *A.* 262, 297). Plates, v. sol. ether. H_2S and alcoholic NH_3 convert it into the thio-amide $C_2HN_3Ph.CS.NH_2$ [132°].

Phenyl-osotriazole dicarboxylic acid  $\left.\begin{array}{l}C(CO_2H){:}N\\C(CO_2H){:}N\end{array}\right>NPh$. [256°]. Formed by oxidising phenyl-di-methyl-osotriazole with $KMnO_4$ (Pechmann, *A.* 262, 311). Crystalline powder. After fusion it melts at 184°.—CaA'': needles.—Ag_2A''.

PHENYL-OSOTRIAZOLE CARBOXYLIC ALDEHYDE  $\left.\begin{array}{l}C(CHO){:}N\\CH\;-\;-\;N\end{array}\right>NPh$. [70°]. Formed by boiling its oxim with dilute H_2SO_4 (Pechmann, *A.* 262, 294). Insol. cold water.

Oxim $C_2HPhN_3.CH{:}NOH$. [115°]. A product of the action of alkalis on the compound $CH(NOH).C(N_2HPh).CH(NOAc)$.

Phenyl-hydrazide $C_2HPhN_3.CH{:}N_2HPh$. [118°–140°]. Plates, v. sol. alcohol.

PHENYL-OSOTRIAZYL ALCOHOL  $\left.\begin{array}{r}CH_2(OH).C{=}N\\CH{:}N\end{array}\right>NPh$. [67°]. Formed, together with the carboxylic acid, by warming the aldehyde with conc. NaOHAq (Pechmann, *A.* 262, 296). Prisms, v. e. sol. alcohol, sl. sol. cold Aq.

PHENYL-OSOTRIAZYL-AMINE $C_9H_{10}N_4$ *i.e.*  $\left.\begin{array}{r}CH_2(NH_2).C{=}N\\CH{:}N\end{array}\right>NPh$. (233° at 100 mm.). Formed from $C_2HPhN_3.CS.NH_2$ by treatment in alcoholic solution with Zn and HCl (Pechmann, *A.* 262, 300).—$B'HCl$. [229°]. Tables.—$B'_2H_2PtCl_6$. Prisms.—**Di-thio-carbamate.** [123°]. Tables.

PHENYL-OXALACETIC ETHER $C_{14}H_{16}O_5$ *i.e.* $CO_2Et.CO.CHPh.CO_2Et$. Formed by the action of Na on a mixture of oxalic ether and phenyl-acetic ether (Wislicenus, *B.* 20, 591; *A.* 246, 339). Oil, decomposed by distillation, v. sol. alkalis. $FeCl_3$ colours its alcoholic solution red. Boiling dilute H_2SO_4 gives CO_2 and phenyl-pyruvic acid [155°].

Phenyl-hydrazide $CO_2Et.C(N_2HPh).CHPh.CO_2Et$. [70°]. Needles (from dilute alcohol), v. sol. ether.

Ethyl ether of the semi-nitrile $CN.CHPh.CO.CO_2Et$. [130°]. Formed from phenylacetonitrile, oxalic ether, and Na or NaOEt (Erlenmeyer, jun., *B.* 22, 1483). Plates. $FeCl_3$ colours its alcoholic solution green.

PHENYL-OXAMIC ACID *v.* Oxalic acid.

PHENYL-OXAMIDE *v.* Oxalic acid.

PHENYL-OXAMIDE CARBOXYLIC ACID *v.* Oxalic acid.

PHENYL-OXANTHRANOL $C_{20}H_{14}O_2$ *i.e.*

$C_6H_4\left<\begin{matrix}CPh(OH)\\CO\end{matrix}\right>C_6H_4$. [208°]. Formed by oxidation of phenyl-anthranol with $K_2Cr_2O_7$ and HOAc (Baeyer, *A.* 202, 58). Colourless tables, insol. water, sol. alcohol. Conc. H_2SO_4 forms a purple solution. Reduced by zinc-dust and HOAc to phenyl-anthranol. Benzene and H_2SO_4 form crystalline $C_{26}H_{18}O$.

Acetyl derivative $C_{20}H_{13}AcO_2$. [196°].

Reference.—Di-chloro- and Oxy-phenyl-oxanthranol.

PHENYL-OXAZOLE C_9H_7NO *i.e.*

$CPh\left<\begin{matrix}CH.O\\N:CH\end{matrix}\right.$ [6°]. (221°). Formed by heating bromo-acetophenone with formamide at 140° (Lewy, *B.* 20, 2578; Blümlein, *B.* 17, 2580).—B'HCl. [80°].—$B'_2H_2PtCl_6$ 2aq: yellow needles.

Di-phenyl-oxazole

$CPh\left<\begin{matrix}CH.O\\N:CPh\end{matrix}\right.$ [103°]. (339°). Formed by heating ω-bromo-acetophenone with benzamide at 145° (B.; L.). Plates (from alcohol).—B'HCl. Needles.

Phenyl-iso-oxazole

$CH\left<\begin{matrix}CPh.O\\CH:N\end{matrix}\right.$ [23°]. Formed from the oxim of benzoyl-acetic aldehyde and AcCl (Claisen a. Stock, *B.* 24, 134).

PHENYL-OXAZOLE DIHYDRIDE C_9H_9NO *i.e.*

$CH_2\left<\begin{matrix}CH_2.O\\N=CPh\end{matrix}\right.$ (243°). Formed by warming bromo-ethyl-benzamide with alkalis (Gabriel a. Heymann, *B.* 23, 2495). Liquid, smelling like phenyl-thiazole dihydride. Miscible with alcohol and ether, sl. sol. water. HBrAq forms bromo-ethyl-benzamide and $CH_2(OBz).CH_2NH_2$.—$B'_2H_2PtCl_6$.—$B'_2H_2Cr_2O_7$.—$B'C_6H_3N_3O_7$. [177°].

DI-PHENYL OXIDE $C_{12}H_{10}O$ *i.e.* Ph_2O. Mol. w. 170. [28°]. (253°). $\mu_A = 1{\cdot}5675$ at 25°.

Formation.—1. By distilling cupric benzoate (List a. Limpricht, *A.* 90, 190).—2. By warming diazobenzene sulphate or chloride with phenol (Hofmeister, *B.* 3, 747; *A.* 159, 204; Hirsch, *B.* 23, 3709).—3. By heating phenol with $ZnCl_2$ at 350°, the yield being 6 p.c. (Merz a. Weith, *B.* 14, 187).—4. By heating phenol with $AlCl_3$ (M. a. W.).—5. Together with diphenylene ketone oxide and a body melting at 111°, by distilling sodium salicylate with phenyl phosphate (R. Richter, *J. pr.* [2] 28, 273).

Preparation.—By distilling $Al(OPh)_3$ (Gladstone a. Tribe, *C. J.* 41, 6).

Properties.—Prisms (from cold alcohol), smelling like geraniums, almost insol. water and KOHAq. Conc. H_2SO_4 forms $O(C_6H_4.SO_3H)_2$, which forms $Na_2A''x$aq, BaA'', and Ag_2A''.

References.—Di-amido-, Di-bromo-, and Di-nitro- and Di-oxy- Di-phenyl oxide.

PHENYL-OXY-ACETAMIDINE *v.* Mandel-amidine.

PHENYL-OXY-ACETIC ACID *v.* Mandelic acid.

DI-PHENYL-OXY-ANGELIC ACID *v.* *Di-hydro*-corniculario acid.

PHENYL *p*-OXY-BENZYL KETONE $C_6H_5.CO.CH_2.C_6H_4OH$. [129°]. Formed from $CH_2Bz.C_6H_4NH_2$ by the diazo- reaction (Ney, *B.* 21, 2449). White spangles (from water).

Acetyl derivative. [87°]. Plates.

Isomeride *v.* Benzoïn.

PHENYL-OXY-BENZYL-UREA $C_{14}H_{14}N_2O_2$ *i.e.* [1:2] $C_6H_4(OH).CH_2.NH.CO.NHPh$. Formed by warming $C_6H_4(OH).CH_2NH_2$ with phenyl cyanate and benzene. Needles, sol. alcohol and ether.

Methyl derivative [1:2] $C_6H_4(OMe).CH_2.NH.CO.NHPh$. [145°]. Formed from $C_6H_4(OMe).CH_2NH_2$ and phenyl cyanate (Goldschmidt a. Ernst, *B.* 23, 2743).

PHENYL-OXY-BROMO-PROPIONIC ACID *v.* Bromo-oxy-phenyl-propionic acid.

PHENYL OXYBUTYL KETONE $C_{11}H_{14}O_2$ *i.e.* $C_6H_5.CO.CH_2.CH_2.CH_2.CH_2OH$. [41°]. Formed by boiling the anhydride of its carboxylic acid with water (Perkin, jun., *C. J.* 51, 733; 57, 310). Iridescent plates, v. sol. alcohol. If left to stand over H_2SO_4 it is converted into the anhydride.

Oxim $C_6H_5.C(NOH).C_4H_8OH$. [57°]. Minute plates, sl. sol. ligroin.

Anhydride $C_{11}H_{12}O$ *i.e.*

$CH_2\left<\begin{matrix}CH:CPh\\CH_2.CH_2\end{matrix}\right>O$. (250° at 720 mm.). Formed by heating its carboxylic acid at 200° (Perkin, *B.* 16, 1792; 19, 2559; *C. J.* 51, 730). Oil. Converted by HBrAq into phenyl bromo-butyl ketone.

PHENYL OXY-BUTYL KETONE CARBOXYLIC ACID. *Anhydride* $C_{12}H_{12}O_3$ *i.e.*

$CH_2\left<\begin{matrix}C(CO_2H):CPh\\CH_2\text{——}CH_2\end{matrix}\right>O$. *Benzoyl-tetramethylene carboxylic acid. Phenyl dehydrohexone carboxylic acid.* [144°]. Formed by saponification of its ether, which is made by the action of trimethylene bromide on sodium benzoyl-acetic ether (Perkin, jun., *C. J.* 51, 726; *B.* 19, 2557). Monoclinic crystals, $a:b:c = 2{\cdot}638:1:3{\cdot}398$; $\beta = 74°41'$. V. sol. alcohol and ether. Converted by conc. HBrAq in the cold into $C_6H_5.CO.C_4H_8Br$.—CaA''.—PbA'': white pp.—AgA': white pp.

Ethyl ether EtA'. [60°]. Monoclinic prisms; $a:b:c = 1{\cdot}002:1:{\cdot}591$; $\beta = 68°\,34'$.

Reference.—Nitro-phenyl oxy-butyl ketone anhydride carboxylic acid.

PHENYL-OXY-BUTYRIC ACID *v.* Oxy-phenyl-butyric acid.

PHENYL OXY-ψ-CUMYL KETONE $C_6H_5.CO.C_6HMe_3OH$. [187°]. Formed by the action of nitrous acid on phenyl amido-ψ-cumyl ketone (Fröhlich, *B.* 17, 1806). Plates, v. sol. alcohol, sol. alkalis.

PHENYL OXYETHYL SULPHONE $C_6H_5.SO_2.C_2H_4OH$. Formed by heating glycollic chlorhydrin with sodium-benzene sulphinate and a little water at 120° (Otto, *J. pr.* [2] 30, 186). Prepared by boiling $C_2H_4(SO_2C_6H_5)_2$ with KOHAq. Liquid, sl. sol. water, miscible with alcohol and ether. *Reactions.* — 1. Conc. H_2SO_4 forms $C_6H_5.SO_2.C_2H_4.O.SO_3H$, which yields $3\frac{1}{2}BaA'_2$ aq, crystallising from water in needles.—2. *Sodium-amalgam* reduces it to alcohol and $Ph.SO_2H$ or PhSH.—3. PCl_5 forms $PhSO_2.C_2H_4Cl$, crystallising from benzene in six-sided tablets [56°].—4. PCl_3 forms the sparingly soluble **anhydride** $(Ph.SO_2.C_2H_4)_2O$ [70°].—5. Aqueous NH_3 at 120° forms $(Ph.SO_2.C_2H_4)_2NH$.—6. *Chromic acid* oxidises it to $Ph.SO_2.CH_2.CO_2H$

Acetyl derivative $C_{10}H_{12}SO_4$. Oil.

Benzoyl derivative $Ph.SO_2.C_2H_4.OBz$ [125°].

PHENYL OXY-METHYL KETONE *v.* BENZOYL-CARBINOL.

PHENYL-OXY-NAPHTHYL KETONE. *Ethyl derivative* $C_{10}H_6(OEt).CO.C_6H_5$. [75°]. Formed from $C_{10}H_7.OEt$, BzCl, and $AlCl_3$ (Gattermann, *B.* 23, 1209). Needles.

Phenyl-di-oxy-naphthyl ketone

$C_6H_5.CO.C_6H_3<\begin{matrix}C(OH):CH\\C(OH):CH\end{matrix}$ [191°]. Formed by boiling (a)-benzoyl-naphthoquinone with $SnCl_2$ and alcohol (Kegel, *A.* 247, 183). White plates.

Acetyl derivative. [155°]. Plates.

Isomeride *v.* DI-OXY-PHENYL-NAPHTHYL-KETONE.

PHENYL-OXYPHENYLBIAZYL-HYDRAZINE

$\begin{matrix}NPh.N\\CO\ .O\end{matrix}>C.NH.NHPh.$ [181°]. Formed by heating di-phenyl-carbazide with $COCl_2$ at 100° (Freund a. Kuh, *B.* 23, 2831). White crystals, insol. benzene. Oxidised by $FeCl_3$ to $C_2N_2PhO_2.N:NPh$ [200°].

PHENYL-OXY-PHENYLTHIOBIAZYL-HYDRAZINE

$\begin{matrix}NPh.N\\CO-S\end{matrix}>C.NH.NHPh.$ [124°]. Formed by the action of $COCl_2$ on di-phenyl-thiocarbazide, the resulting $C_2N_2PhSO.N:NPh$ [140°] being reduced by alcoholic ammonium sulphide (Freund a. Kuh, *B.* 23, 2827). Needles.

DI-PHENYL-DIOXYPHENYLENE DI-KETONE *v.* DIOXYPHENYLENE DIPHENYL DI-KETONE.

PHENYL-OXY-PIVALIC ACID *v.* β-OXY-PHENYL-VALERIC ACID.

PHENYL-OXY-PROPIONIC ACID *v.* OXY-PHENYL-PROPIONIC ACID.

DI-PHENYL OXYPROPYLENE DISULPHONE $CH(OH)(CH_2.SO_2.C_6H_5)_2$. Formed by oxidation of the product of the action of NaSPh on dichlorhydrin (Otto a. Rössing, *B.* 23, 758). Oil, v. sol. alcohol.

Benzoyl derivative. [150°]. Needles.

DI-PHENYL OXY-PROPYL SULPHONE. *Anhydride* $(C_6H_5.SO_2.CH_2.CH_2.CH_2)_2O$. [85°]. Formed by heating di-phenyl trimethylene di-sulphone with alcoholic potash at 120° (Otto, *B.* 24, 1833). Hexagonal tables, insol. water.

PHENYL OXYTOLYL KETONE. *Methyl derivative.* $C_6H_5.CO.C_6H_3Me.OMe$. [80°]. Formed from $C_6H_4Me(OMe)$, BzCl, and $AlCl_3$ (Koenigs a. Carl, *B.* 24, 3897). Crystals.

PHENYL-OXY-VALERIC ACID *v.* OXY-PHENYL-VALERIC ACID.

Di-phenyl-oxy-valeric acid *v.* *Tetrahydro-*CORNICULARIC ACID.

PHENYL-PARABAMIC ACID *v.* PARABAMIC ACID.

PHENYL-PARACONIC ACID *v.* *Anhydride* of OXY-BENZYL-SUCCINIC ACID and NITRO-PHENYL-PARACONIC ACID.

DI-PHENYL-PENTADECYL TRICYANIDE $C_3N_3Ph_2(CH_2)_{14}CH_3$. [64°]. (328° at 13 mm.). Formed by heating benzonitrile with palmityl chloride and $AlCl_3$ from 40° to 100° (Krafft a. Hansen, *B.* 22, 809). Globular groups of needles (from isobutyl alcohol), v. sol. ether.

PHENYL PENTADECYL KETONE $C_6H_5.CO.C_{15}H_{31}$. [59°]. (251° at 15 mm.). Formed from palmityl chloride, benzene, and $AlCl_3$ (Krafft, *B.* 19, 2982; 21, 2266). Plates (from alcohol), sol. ether. Yields benzoic and pentadecoic acids on oxidation.

Reference.—OXY-PHENYL PENTADECYL KETONE.

PHENYL-PENTANE *v.* AMYL-BENZENE.

PHENYL-PENTANE DICARBOXYLIC ACID $CO_2H.C_6H_4.CEt_2.CO_2H$. [198°]. Formed by the action of KOHAq upon its **anhydride**

$C_6H_4<\begin{matrix}CEt_2.CO\\CO\ \ .O\end{matrix}$ [53°], which is got by the action of alcoholic potash and EtI on di-oxy-ethyl-isoquinoline (Pulvermacher, *B.* 20, 2494). Crystalline.—BaA″.—Ag_2A''; yellow powder.

Phenyl-pentane tricarboxylic ether $CHEt(CO_2Et).C(CH_2Ph)(CO_2Et)_2$. (336° cor.). S.G. $\frac{20}{4}$ 1·0899. μ_D = 1·4867 at 20°. Formed from sodium butane tricarboxylic ether and benzyl chloride (Bischoff a. Mintz, *B.* 23, 654). Yields, on saponification, two benzyl-ethyl-succinic acids [157·5°] and [123·5°].

Phenyl-pentane tricarboxylic acid $CMe_2(CO_2H).C(CH_2Ph)(CO_2H)_2$. [178°]. *Ethyl ether* Et_3A'''. (337° cor.). S.G. $\frac{20}{4}$ 1·0950. μ_D = 1·4831 at 20°. Formed in like manner from isobutane tricarboxylic ether (B. a. M.). Yields, on saponification, the acid and also benzyl-di-methyl-succinic acid [155°].

Phenyl-pentane tri-carboxylic acid $CHMe(CO_2H).CH_2.C(CH_2Ph)(CO_2H)_2$. [130°]. One of the acids got by saponifying the product of the action of benzyl chloride on sodium isobutane tricarboxylic ether (Bischoff, *B.* 23, 1947). Plates (from water).

Di-phenyl-pentane tetra-carboxylic ether $CH_2(C(CO_2Et)_2.CH_2Ph)_2$. (c. 280° at 20 mm.). Formed from disodium propane tetra-carboxylic ether and benzyl chloride (Dressel, *A.* 256, 191). Thick oil.

PHENYL-PENTENOIC ACID $C_{11}H_{12}O_2$ *i.e.* $C_6H_5.C_4H_6.CO_2H$. *Hydrocinnamenylacrylic acid.* [31°]. Formed by reduction of phenyl-pentinoic acid by sodium-amalgam (Baeyer a. Jackson, *B.* 13, 122). Plates. Yields di-oxy-phenyl-valeric acid on oxidation by alkaline $KMnO_4$ (Fittig a. Mayer, *A.* 268, 51).

Dibromide. [109°]. Prisms.

PHENYL-PENTINOIC ACID $C_{11}H_{10}O_2$ *i.e.* $C_6H_5.CH:CH.CH:CH.CO_2H$. *Styryl-acrylic acid.* [166°]. Formed from cinnamic aldehyde, Ac_2O, and NaOAc (Perkin, *C. J.* 31, 403; Fittig, *A.* 268, 50). Prisms (from water). On oxidation by alkaline $KMnO_4$ it yields benzoic aldehyde and racemic and oxalic acids (Doebner, *B.* 23, 2374).—SrA'_2 2aq.—Ag_2A''.

Chloride $C_{12}H_{13}OCl$. [25°].

Amide. [186°]. Tables (from alcohol).

Di-phenyl-pentinoic acid $C_6H_5CH:CH.CH:CPh.CN$. [119°]. Formed from cinnamic aldehyde, phenyl-acetonitrile, and NaOEt (Freund a. Immerwahr, *B.* 23, 2856). Needles, v. sol. alcohol and ether.

Reference.—NITRO- and OXY-PHENYL PENTINOIC ACID.

PHENYL-PHENTRIAZINE. *Dihydride.*

$C_6H_4<\begin{matrix}N=N\\CH_2.NPh\end{matrix}$ [128°]. Formed by adding

$NaNO_2$ to a solution of *o*-amido-benzyl-phenyl-hydrazine or *o*-amido-benzyl-aniline in HClAq at 0° (Busch, *B.* 25, 448). Plates, v. sol. alcohol. Salts.—$B'HCl$.—$B'_2H_2PtCl_6$. [130°].—$B'C_6H_3N_3O_7$. [111°]. Orange-red needles.

PHENYL-PHENTRIAZOLE $C_{12}H_9N_3$ *i.e.* $C_6H_4\lessdot\substack{N\\N}>NPh$. [109°]. Occurs as a by-product in the manufacture of amido-azo-benzene (Gattermann, *B.* 21, 1633). Formed by the action of phenyl-hydrazine on bromo-di-nitro-benzene, the resulting nitro-phenyl-phentriazole $[1:4:5]C_6H_3(NO_2):N_3Ph$ being reduced to amido-phenyl-phentriazole [183°] and NH_2 then eliminated (Kehrmann a. Messinger, *B.* 25, 899).

Isomeride $C_6H_4<\substack{NPh\\N}>N$. *Phenyl-phenylene-azimide.* [90°]. Formed from *o*-amido-diphenylamine and nitrous acid (Schöpff, *B.* 23, 1843). Needles, sol. alcohol.

PHENYL-PHEN-(β)-NAPHTHACRIDINE $C_6H_4<\substack{N\\CPh}>C_{10}H_6$. [198° uncor.]. Formed by heating a mixture of phenyl-(β)-naphthylamine and benzoic acid with P_2O_5 or $ZnCl_2$ (Claus a. Richter, *B.* 17, 1595). Sublimes in white needles.—$B'_2H_2PtCl_6$: glittering yellow needles.

DI-PHENYL PHENYL-ACETYLENE DI-KETONE *v.* DEHYDRO-ACETOPHENONE-BENZIL, vol. i. p. 37.

Di-phenyl-diphenylacetylene diketone *v.* OXYLEPIDEN, vol. iii. p. 137.

PHENYL-PHENYL-AMIDO-ACETIC ACID $C_6H_4Ph.NH.CH_2.CO_2H$. Formed from *p*-amido-diphenyl and chloro-acetic acid (Zimmermann, *B.* 13, 1966). Plates (from hot water).—EtA'. [95°]. Needles (from dilute alcohol).

PHENYL PHENYL-AMIDO-ETHYL KETONE $C_6H_5.CO.C_2H_4NHPh$. [38°]. Formed from $C_6H_5.CO.C_2H_4Br$ and aniline (Pampel a. Schmidt, *B.* 19, 2896). Yellow crystals.

Acetyl derivative. [103°]. Needles.

PHENYL PHENYL-AMYL KETONE $C_{18}H_{20}O$ *i.e.* $C_6H_5.CO.CHPh.CH_2Pr$. [78°]. (330° cor.). Formed from phenyl benzyl ketone, NaOEt, and isobutyl bromide (V. Meyer a. Oelkers, *B.* 21, 1295). Needles. Yields an oxim [118°] crystallising in prisms.

PHENYL-PHENYL-BENZAMIDINE $C_{19}H_{14}N_2$ *i.e.* $CPh\lessdot\substack{NH\\N}>C_6H_3Ph$. [198°]. Formed from $C_6H_3Ph(NO_2).NHBz$, tin, and HOAc (Hübner, *A.* 209, 347). Plates (from alcohol).—$B'HCl$.—$B'_2H_2PtCl_6$.—$B'_2H_2SO_4$: needles, sl. sol. water.

PHENYL-PHENYL BENZYL KETONE $C_{20}H_{16}O$ *i.e.* $C_6H_4Ph.CO.CH_2Ph$. [150°]. (above 360°). Formed from diphenyl, phenyl-acetic chloride, and $AlCl_3$ (Päpcke, *B.* 21, 1339). Plates (from alcohol). Converted by NaOEt and $CSCl_2$ into $C_6H_4Ph.CO.CPh:CS$ [above 320°].

PHENYL PHENYL-BUTYL KETONE $C_6H_5.CO.CHPhPr$. [33°]. (330°). Formed from sodium deoxybenzoïn and *n*-propyl bromide (Bischoff, *B.* 22, 346). Thread-like needles (from alcohol). Yields an **oxim** [100°].

Phenyl phenyl-isobutyl ketone $C_6H_5.CO.CHPhPr$. [48°]. (325°). Yields an **oxim** [70°] and a phenyl-hydrazide [72°].

DI-PHENYL-DI-PHENYL-CARBINOL $(C_6H_4Ph)_2CH.OH$. [151°]. S. (alcohol) 1·25; (ether) 9; (ligroïn) ·5 at 15°. Got by reducing the corresponding ketone with sodium-amalgam (Adam, *A. Ch.* [6] 15, 260; *cf.* Weiler, *B.* 7, 1189). Plates.

PHENYL-DI-PHENYL-CARBINYLAMINE $C_6H_5.C_6H_4.CHPh.NH_2$. [77°]. Got by reducing the oxim $C_6H_5.C_6H_4.C(NOH).C_6H_5$ by sodium amalgam (Koller, *M.* 12, 508). Needles (from ether), insol. water. Conc. H_2SO_4 forms a deep-violet colour, becoming claret-red on warming.—$B'HOAc$. [161°]. White needles (from water).—$B'HCl$. [252°]. White needles.—$B'HNO_3$. [211°].—$B'_2H_2PtCl_6$4aq. [191°]. Yellow needles.

Phenyl-triphenylcarbinyl-amine $NHPh.CPh_3$. [146°]. Formed from aniline and CPh_3Br (Elbs, *B.* 17, 703; Hemilian a. Silberstein, *B.* 17, 746). Hexagonal prisms, v. sol. CS_2. Yields a nitrosamine [c. 156°] and a tetra-sulphonic acid $C_{25}H_{17}(SO_3H)_4N$ which yields easily soluble Ba_2A^{iv} and Cu_2A^{iv}.

PHENYL TRI-PHENYL-CARBINYL KETONE *v.* (β)-BENZPINACOLIN.

DI-PHENYL-DIPHENYLENE-DI-UREA. $NHPh.CO.NH.C_6H_4.C_6H_4.NH.CO.NHPh$. [above 300°]. Concentric needles (from aniline). Formed by adding phenyl cyanate (2 mols.) to an ethereal solution of benzidine (Kuhn, *B.* 18, 1478).

PHENYL PHENYL-ENNYL KETONE $C_6H_5.CO.CHPh.C_8H_{17}$. [61°]. (350°-355°). Formed from deoxybenzoïn (E. Bischoff, *B.* 22, 348). Yields an oxim [101°] crystallising in long needles.

PHENYLPHENYL-ETHYL ALCOHOL $[1:3]C_6H_4Ph.CHMe.OH$. [86°]. Formed by reducing $C_6H_4Ph.CO.CH_3$ with sodium-amalgam (Adam, *A. Ch.* [6] 15, 257). Crystalline mass. Cannot be distilled.

DI-PHENYL DIPHENYLETHYLENE DI-KETONE $CHPhBz.CHPhBz$. *Bidesyl. Hydro-oxylepiden.* [255°]. Formed as described in vol. iii. p. 139. Needles (from benzene), insol alcohol. On boiling for two hours with alcohol it changes to an isomeride [261°], sol. alcohol (Fehrlin, *B.* 22, 553).

Isomeride. [161°]. *Isobidesyl.* Accompanies bidesyl when prepared from deoxybenzoïn, NaOEt, and I, or from BzCHBrPh, NaOEt, and deoxybenzoïn (Knövenagel, *B.* 21, 1356). Prisms (from alcohol). Reacts with hydroxylamine forming $C_{56}H_{47}N_3O_4$ [110°-120°]. Conc. H_2SO_4 forms with bidesyl and isobidesyl a green solution, turning brown. NH_3 forms tetra-phenyl-pyrrole.

PHENYL PHENYL-ETHYL KETONE $C_6H_5.CO.CHMe.C_6H_5$. [53°]. (318° cor.). Formed from $C_6H_5.CO.CHNa.C_6H_5$ and MeI (V. Meyer a. Oelkers, *B.* 21, 1297). Needles (from alcohol). Forms an oxim [120°].

Phenyl phenyl-ethyl ketone $C_6H_5.CO.CH_2.CH_2.C_6H_5$. [73°]. (above 360°). Formed by reducing phenyl styryl ketone with zinc-dust and HOAc (Schneidewind, *B.* 21, 1325). Plates (from alcohol). Yields an oxim [87°]. Isoamyl nitrite and NaOEt form $C_{15}H_{13}NO_2$ [126°].

Phenyl diphenyl-ethyl ketone $C_6H_5.CO.CHPh.CH_2Ph$. [120°]. Formed from phenyl benzyl ketone, NaOEt, and benzyl chloride (V. Meyer a. Oelkers, *B.* 21, 1300). Needles (from alcohol). Yields an oxim [208°].

PHENYL PHENYL-ETHYL KETONE CARBOXYLIC ACID $C_6H_5.CO.CHPh.CH_2.CO_2H$. [152°] (J. a. M.); [161°] (M. a. O.). Formed by oxidising dehydro-acetone-benzil with CrO_3 and HOAc (Japp a. Miller, *B.* 18, 184). Needles.—BaA'_2 2aq.—AgA'.

Ethyl ether EtA'. Formed from Ph.CO.CHNaPh and $ClCH_2CO_2Et$ (V. Meyer a. Oelkers, *B.* 21, 1305). When heated it yields an anhydride  $\mathrm{O}<\begin{array}{l}\mathrm{CO\ .CH_2}\\ \mathrm{CPh{:}CPh}\end{array}$ [152°], whence ammonia forms  $\mathrm{NH}<\begin{array}{l}\mathrm{CO\ .CH_2}\\ \mathrm{CPh{:}CPh}\end{array}$ [189°]. Phenyl-hydrazine acting on desylacetic acid forms $C_{22}H_{18}N_2O$ [110°] and $(C_{22}H_{17}N_2O)_2$ [243°]. The former,  $\mathrm{NHPh.N}<\begin{array}{l}\mathrm{CO\ .CH_2}\\ \mathrm{CPh{:}CPh}\end{array}$? may be reduced by Na and isoamyl alcohol to  $\mathrm{NH}<\begin{array}{l}\mathrm{CO—CH_2}\\ \mathrm{CHPh.CHPh}\end{array}$ [207°]. Aniline converts the acid into  $\mathrm{NPh}<\begin{array}{l}\mathrm{CO\ .CH_2}\\ \mathrm{CPh{:}CPh}\end{array}$ [190°] and  $\mathrm{NPh}<\begin{array}{l}\mathrm{CO\ .CH\ .CH\ .CO}\\ \mathrm{CPh\ CPh.CPh{:}CPh}\end{array}>\mathrm{NPh}$ not melted at 300°.

Phenyl phenyl-ethyl ketone carboxylic acid. *Methyl ether* $C_6H_5.CO.CH(CO_2Me).CH_2Ph$. (c. 253° at 50 mm.). Formed from methyl benzoyl-acetate, NaOEt, and benzyl chloride (Perkin a. Calman, *C. J.* 49, 155).

Phenyl di-phenyl-ethyl-ketone carboxylic acid $C_{22}H_{18}O_3$ *i.e.* $C_6H_5.CO.CH_2.CPh_2.CO_2H$. [183°]. Formed by heating the lactone of oxy-tri-phenyl-crotonic acid with alcoholic potash (Japp a. Klingemann, *C. J.* 57, 681). Plates. Reduced by boiling HIAq to tri-phenyl-butyro-lactone. Phenyl-hydrazine in alcoholic solution yields $C_{28}H_{22}N_2O$, which is reduced by Na and isoamyl alcohol to oxy-tri-phenyl-pyrrole di-hydride $C_{22}H_{19}NO$.—NH_4A'.—AgA'. On heating with alcohol and hydroxylamine hydrochloride it forms $C_{22}H_{17}NO_2$ [152°] and $C_{22}H_{17}NO$ [143°].

Methylamide $C_{23}H_{21}NO_2$. [156°]. Formed from tri-phenyl-crotolactone and methylamine.

Ethylamide. [130°]. Needles.

Phenyl tri-phenyl-ethyl ketone carboxylic acid. *Methylamide* $C_6H_5.CO.CHPh.CPh_2.CONHMe$. [260°]. Formed by heating the lactone of oxy-tetra-phenyl-crotonic acid with alcoholic NH_2Me at 100° to 200° (Klingemann a. Laycock, *B.* 24, 514). Plates, sl. sol. alcohol. Yields, on distillation,  $\mathrm{NMe}<\begin{array}{l}\mathrm{CPh{:}CPh}\\ \mathrm{CO\ .CPh_2}\end{array}$ [158°].

PHENYL PHENYL-HEPTYL KETONE $C_6H_5.CO.CHPh.C_6H_{13}$. [59°]. (345°). Needles or plates (from alcohol). Yields an oxim [89°] (Bischoff, *B.* 22, 347).

PHENYL-DI-PHENYL-HYDRAZINE $NHPh.NHC_6H_4Ph$. [127°]. Formed by reducing $C_6H_5.N_2.C_6H_4Ph$ with ammonium sulphide (Locher, *B.* 21, 911). Needles or plates (from dilute alcohol). Yields a di-acetyl derivative [203°].

PHENYL-DI-PHENYL KETONE *v.* PHENYL-BENZOPHENONE.

PHENYL-PHENYL MERCAPTAN $C_{12}H_{10}S$ *i.e.* $C_6H_4Ph.SH$. [111°]. Formed by educing $C_6H_4Ph.SO_2Cl$ with tin and HCl (Gabriel a. Deutsch, *B.* 13, 386).—$Pb(S.C_6H_4Ph)_2$. Reddish-brown pp.—$C_{12}H_9SMe$. [108°]. Needles (*Obermayer, B. 20, 2927*).

DI-PHENYL-DI-PHENYL-METHANE $(C_6H_4Ph)_2CH_2$. [161°]. (360°). Formed from diphenyl, methylal, HOAc, and H_2SO_4 (Weiler, *B.* 7, 1188). Formed also from diphenyl, CH_2Cl_2, and $AlCl_3$; the yield being bad (Adam, *A. Ch.* [6] 15, 254).

DI-PHENYL DI-PHENYL-METHYLENE DISULPHIDE $CPh_2(SPh)_2$. [139°]. Formed by passing dry HCl into a hot mixture of benzophenone, phenyl mercaptan, and $ZnCl_2$ (Baumann, *B.* 18, 889). Prisms (from ether).

PHENYL-PHENYL DI-PHENYL-ETHYL KETONE $C_6H_4Ph.CO.CHPh.CH_2Ph$. [158°]. Formed from $C_6H_4Ph.CO.CH_2Ph$, NaOEt, and benzyl chloride (Päpcke, *B.* 21, 1339). Needles (from alcohol). Yields an oxim [175°].

PHENYL PHENYL-PROPINYL KETONE CARBOXYLIC ACID CPh⋮C.CHBz.CO_2H. [135°]. (c. 275° at 40 mm.). Formed from di-benzoyl-propionic ether and alcoholic potash (Kapf a. Paal, *B.* 21, 1488). Yellow needles or plates, insol. water. Phenyl-hydrazine forms $C_{29}H_{24}N_4O$ [100°]. Boiling with alcohol and HClAq forms di-phenyl-furfurane carboxylic acid [217°]. Alcoholic NH_3 yields di-phenyl-pyrrole carboxylic ether.—KA'2aq: yellow needles (from alcohol).

PHENYL α-PHENYL-PROPYL KETONE $C_6H_5.CO.CHEtPh$. [58°]. (324° cor.). Formed from phenyl benzyl ketone, NaOEt, and EtI (V. Meyer a. Oelkers, *B.* 21, 1299). Needles. Yields an oxim [130°].

Phenyl phenyl-propyl ketone $C_6H_5.CO.CH_2.CHPh.CH_3$ or $C_6H_5.CO.CMe_2Ph$ [70°]. (340°–345° i.V.). Formed by heating acetophenone with HI and P at 140° (Graebe, *B.* 7, 1625). Plates (from alcohol), v. e. sol. ether.

PHENYL DI-PHENYL-PROPYL THIO-UREA $NHPh.CS.NH.CH_2.CHPh.CH_2Ph$. [129°]. Formed from di-phenyl-propyl-amine and phenyl thiocarbimide (Freund a. Remse, *B.* 23, 2862).

PHENYL PHENYL-PYRAZYL KETONE $C_3H_2PhN_2.CO.C_6H_5$. [123°]. Formed by heating phenyl-pyrazole with BzCl at 245° (Balbiano, *G.* 19, 139). Needles (from dilute alcohol). Yields an oxim [154°] and a phenyl-hydrazide [140°].

DI-PHENYL-DI-PHENYL SULPHIDE $C_{24}H_{18}S$ *i.e.* $(C_6H_4Ph)_2S$. [172°]. Formed by distilling $Pb(S.C_6H_4Ph)_2$ (Gabriel a. Deutsch, *B.* 13, 386). Plates, sol. alcohol and ether.

Di-phenyl di-phenyl disulphide $(C_6H_4Ph)_2S_2$. [150°]. Formed by atmospheric oxidation of $C_6H_4Ph.SH$ (G. a. D.). Needles, sol. alcohol and CS_2.

PHENYL-PHENYL SULPHOCYANIDE $C_6H_4Ph.SCN$. [84°]. Formed from $Pb(SC_6H_4Ph)_2$ and ICy (Gabriel a. Deutsch, *B.* 13, 389). White crystals.

DI-PHENYL-DI-PHENYL SULPHONE $(C_6H_4Ph)_2SO_2$. [216°]. Made by oxidising $(C_6H_4Ph)_2S$ with $KMnO_4$ (Gabriel a. Deutsch, *B.* 13, 387). Plates, sl. sol. ether.

PHENYL-PHENYL-SULPHONO-BENZAMIDINE $PhC(NPhH){:}NSO_2Ph$. [139°]. Formed by the action of aniline on the imido-chloride obtained from the anilide of benzene sulphonic acid by the action of PCl_5 (Wallach a. Gossmann, *A.* 214, 214). Narrow plates (from alcohol). Appears not to combine with HCl. On dry distillation it gives di-phenylamine, benzonitrile, SO_2, and phenyl sulphides.

PHENYL-PHENYL-THIOCARBIMIDE $C_6H_4Ph.N:CS$. [58°]. Formed by distilling $(C_6H_4Ph.NH)_2CS$ with P_2O_5 (Zimmermann, *B.* 13, 1964). Needles.

PHENYL PHENYL-THIO-GLYCOLLIC ACID $C_6H_4Ph.S.CH_2.CO_2H$. [170°]. Formed from chloro-acetic acid and $C_6H_4Ph.SNa$ (Gabriel a. Deutsch, *B.* 13, 389). Colourless crystals, sl. sol. water.

Phenyl-phenyl-di-thio-di-glycollic acid $C_{12}H_8(S.CH_2.CO_2H)_2$. [252°]. Formed from $C_{12}H_8S_2Pb$ and $ClCH_2.CO_2H$. Crystals.

DI-PHENYL-DI-PHENYL-THIO-UREA $CS(NH.C_6H_4Ph)_2$ [228°]. Formed from *p*-amido-diphenyl and CS_2 (Zimmermann, *B.* 13, 1963). Plates.

PHENYL PHENYL DI-TOLYL-CARBINYL KETONE *v.* PHENYL-TOLYL-PINACOLIN.

PHENYL-PHENYL-*p*-TOLYL-CARBINYL-UREA $NHPh.CO.NH.CHPh.C_6H_4Me$. [206°]. Formed from $C_6H_4Me.CHPh.NH_2$ and phenyl cyanate (Goldschmidt a. Stöker, *B.* 24, 2802).

PHENYL PHENYL-DI-XYLYL-CARBINYL KETONE *v.* PHENYL-XYLYL-PINACOLIN.

PHENYL PHOSPHATES.

Mono-phenyl di-hydrogen phosphate $C_6H_5O.PO(OH)_2$. *Phenyl-phosphoric acid.* [98°]. A product of the action of P_2O_5 on phenol (Rembold, *Z.* 1866, 652; Jacobsen, *B.* 8, 1519; Rapp, *A.* 224, 157). Deliquescent needles. Partially decomposed by boiling water into phenol and phosphoric acid. Yields phenol and HPO_3 on distillation.—CaA″.—BaA″: prisms.

Chloride $C_6H_5O.POCl_2$. (242°). A product of the action of $POCl_3$ on phenol. Formed also from $C_6H_5O.PCl_4$ and SO_2 (Anschütz a. Emery, *A.* 253, 110).

Di-phenyl hydrogen phosphate $(C_6H_5O)_2PO.OH$. [56°] (R.). A product of the action of P_2O_5 on phenol. Formed also by boiling $(PhO)_3PO$ (1 mol.) with aqueous KOH (1 mol.) (Glutz, *A.* 143, 193), and by decomposing the chloride with water.—BaA'_2.—AgA′.—NH_3PhA'. [c. 160°] (Wallach, *B.* 8, 1235).

Chloride $(C_6H_5O)_2POCl$. (315° at 272 mm.). Formed from phenol and $POCl_3$. Oil, slowly decomposed by water.

Anilide $(C_6H_5O)_2PO.NHPh$. [129°]. Six-sided tables, v. sl. sol. water (W.).

Tri-phenyl phosphate $(C_6H_5O)_3PO$. [45°] (J.). (245° at 11 mm.) (A. a. E.) Formed, together with chloro-benzene, by the action of PCl_5 on phenol (Williamson a. Scrugham, *C. J.* 7, 240). Formed also from phenol and $POCl_3$ (Jacobsen), or PCl_5 (Glutz), followed by water. It is also a product of the action of water on $C_6H_5O.PCl_4$ (Anschütz a. Emery, *A.* 253, 110).

Preparation.—A mixture of phenol (280 pts.) and phosphorus oxychloride (150 pts.) is heated to boiling with an inverted condenser for 16 hours, the excess of phenol is removed by distillation or by shaking with dilute NaOH; the yield is 90 p.c. of the theoretical (Heim, *B.* 16, 1763).

Properties.—Needles, insol. water, sl. sol. alcohol, v. sol. ether.

Reactions.—By distillation with sodium acetate or benzoate it gives phenylacetate or benzoate. Heated with potassium sulphide it yields tri-phenyl-thio-phosphate $PS(OC_6H_5)_3$, together with phenol and some diphenyl and di-phenyl oxide. On distilling with MgO, PbO, ZnO, or CaO the chief product is phenyl, together with some diphenylene-oxide (Kreysler, *B.* 18, 1716). Chlorine passed into its cold ethereal solution forms $(C_6H_5O)_3PCl_2$ (A. a. E.).

Reference.—NITRO-PHENYL-PHOSPHATES.

PHENYL-PHOSPHINE $C_6H_5PH_2$. Mol. w. 110. (161°). S.G. $\frac{15}{15}$ 1·001. A product of the action of alcohol on $C_6H_5PI_3H$ and on $C_6H_5PCl_2$ (Michaelis, *B.* 7, 6; 10, 807; 12, 338; *A.* 181, 303). Pungent liquid.

Reactions.—1. Absorbs oxygen, forming $C_6H_5PHO.OH$ [70°].—2. Sulphur at 100° forms liquid $C_6H_5PH_2S$ and solid $(C_6H_5P)_3S$ [138°].—3. CS_2 at 150° forms $C_{14}H_{12}P_2S_3$.

Salts.—$C_6H_5PH_3I$. Needles.—$B'_2H_2PtCl_6$.

Phenyl-di-chloro-phosphine $C_6H_5PCl_2$. *Phosphenyl chloride.* Mol. w. 179. (225° cor.). S.G. $\frac{0}{4}$ 1·3428 (Thorpe, *C. J.* 37, 347). Formed by passing benzene and PCl_3 through a red-hot tube. Formed also by heating $HgPh_2$ with PCl_3 at 180°, and by the action of $AlCl_3$ on a mixture of benzene and PCl_3 (Michaelis, *B.* 12, 1009; *A.* 181, 280). Pungent fuming liquid, decomposed by water into HCl and $C_6H_5PHO.OH$ [70°]. Chlorine forms $C_6H_5PCl_4$ [73°], which is split up at 180° into C_6H_5Cl and PCl_3, and is converted by water into $C_6H_5PO(OH)_2$. $SbCl_5$ forms $C_6H_5PCl_4SbCl_5$, an unstable yellow crystalline powder. Br yields $C_6H_5PCl_2Br_2$ [208°] and $C_6H_5PCl_2Br_4$. HI forms $C_6H_5PHI_3$. H_2S yields oily $(C_6H_5PS)_2$ and crystalline $C_{24}H_{20}N_2S_3$ [193°]. S forms liquid $C_6H_5PSCl_2$ (270°) (Köhler, *B.* 13, 464).

Phenyl-di-bromo-phosphine $C_6H_5PBr_2$. [257°]. Got from $HgPh_2$ and PBr_3 (Michaelis, *B.* 9, 519). Liquid. Br yields $C_6H_5PBr_4$ [207°] and $C_6H_5PBr_6$.

Di-phenyl-phosphine $(C_6H_5)_2PH$. (c. 280°). S.G. $\frac{12}{12}$ 1·07. Formed, together with the acid $(C_6H_5)_2PO.OH$ by the action of dilute NaOHAq on $(C_6H_5)_2PCl$ (Michaelis a. Gleichmann, *B.* 15, 801; Dörken, *B.* 21, 1508). Oil, v. sol. alcohol. Weak base. Yields $(C_6H_5)_2PO.OH$ on oxidation. CS_2 forms $(C_6H_5)_4P_2H_2CS_2$ [157°].—B′HCl. Crystalline.—$B'_2H_2PtCl_6$.—B′HI.

Di-phenyl-chloro-phosphine $(C_6H_5)_2PCl$. (320°). S.G. $\frac{15}{15}$ 1·229. Formed from $HgPh_2$ and $C_6H_5PCl_2$ at 225° (Michaelis, *B.* 10, 627; 18, 2109; *A.* 207, 208). Formed also by heating $C_6H_5PCl_2$ in a sealed tube for 120 hours at 300° (Dörken, *B.* 21, 1505). Thick liquid, decomposed by water or Na_2CO_3Aq into $(C_6H_5)_2PH$ and $(C_6H_5)_2PO.OH$. Absorbs oxygen from the air forming $(C_6H_5)_2POCl$.

Tri-phenyl-phosphine $P(C_6H_5)_3$. [79°]. (above 360°) (Michaelis, *B.* 15, 802, 1610; *A.* 229, 297). Formed from $C_6H_5PCl_2$, bromo-benzene and Na. Prepared by adding sodium to a mixture of PCl_3 (1 mol.) and C_6H_5Br (3 mols.) diluted with 4 volumes of dry ether and kept cool. The reaction is completed by boiling for 12 hours, and the ether is filtered off and evaporated to crystallisation.

Properties.—Large prisms or tables, sol. alcohol, ether, and benzene, insol. water. Very weak base. Does not combine with CS_2.

Salts.—B′HI. [215°]. Prisms, sol. alcohol, insol. water.—$B'_2H_2PtCl_6$.—$B'HgCl_2$.

Alkylo-halides.—B'MeI. [183°].—B'MeCl aq. [213°]. Crystals, v. e. sol. water and alcohol, insol. ether.—$B'_2Me_2PtCl_6$. [238°]. B'EtI. [165°].—B'PrI. [201·5°].—B'PrI 2aq. [191°].—$B'CH_2PrI$. [177°].—$B'C_5H_{11}I$. [174°].—$B'CH_2PhCl$ aq. [288°].—$B'CH_2PhBr$. [275°].—$B'CH_2PhI$. [253°].—$B'_2CH_2I_2$. [231°].—$B'_2C_2H_4Br_2$. [above 300°].

Benzylo-nitrate $B'C_7H_7NO_3$. [203°]. S. ·338 at 15°. Needles (from water).

Benzylo-picrate $B'C_7H_7C_6H_2N_3O_7$. [248°].

Benzylo-bichromate $(B'C_7H_7)_2Cr_2O_7$.

Benzylo-sulphocyanide $B'C_7H_7SCN$. [189°]. Prisms, v. sol. alcohol, sl. sol. water.

Tri-phenyl-phosphine oxide $(C_6H_5)_3PO$. [153·5°]. (c. 360°). Formed by oxidising tri-phenyl-phosphine with Br_2 and NaOHAq or with conc. HClAq and $KClO_3$. Prisms (containing aq), sl. sol. water, v. e. sol. alcohol. Yields two tri-nitro- compounds [68°] and [242°], the latter of which yields a tri-amido-compound [258°], whence bromine water forms $OP(C_6H_2Br_2(NH_2))_3$ [206°].—$B'HNO_3$. [75°]. Yellow needles, decomposed by water.

Tri-phenyl-phosphine sulphide $(C_6H_5)_3PS$. [157·5°]. Formed from Ph_3P and S in CS_2. Colourless needles, v. sol. alcohol, insol. water.

Tri-phenyl-phosphine selenide $(C_6H_5)_3PSe$. [184°]. Formed from Ph_3P and Se. Needles.

Tetra-phenyl-diphosphine $P_2(C_6H_5)_4$. [67°]. (400°). Formed from $(C_6H_5)_2PCl$ and $(C_6H_5)_2PH$ (Dörken, *B.* 21, 1509). With CS_2 at 138° it forms $Ph_2P.CS.SPH_2Ph_2$ [157°], insol. ether.

PHENYL-PHOSPHINIC ACID *v.* PHENYL-PHOSPHITES.

Di-phenyl-phosphinic acid $(C_6H_5)_2PO.OH$. [190°] (Michaelis, *B.* 8, 922; 11, 885; 15, 802; 18, 2113). Formed by oxidation of $(C_6H_5)_2PCl$ or of di-phenyl-phosphine. Needles, sl. sol. cold alcohol.—CaA'_2 3aq.—AgA': bulky pp.

Ethyl ether EtA'. [165°]. Needles.

Phenyl ether $(C_6H_5)_2PO.OC_6H_5$. [186°]. Formed by oxidising $(C_6H_5)_2POC_6H_5$ (265°–270°), which is got by warming $(C_6H_5)_2PCl$ with phenol. Small needles, sol. hot alcohol, insol. water.

PHENYL PHOSPHITES.

Mono-phenyl dihydrogen phosphite $C_6H_5O.P(OH)_2$. Formed by adding water to $C_6H_5O.PCl_2$ (216°) which is got by the action of PCl_3 on phenol (Noack, *A.* 218, 90; Anschütz, *A.* 239, 310). Uncrystallisable syrup, decomposed by addition of more water into phenol and H_3PO_3.

Isomeride $C_6H_5PO(OH)_2$. *Phenyl phosphinic acid. Phosphenylic acid. Benzene phosphonic acid.* [158°]. S. 23·5 at 15°. Formed by the action of water on $C_6H_5PCl_4$ (Michaelis, *A.* 181, 321). Plates, sol. alcohol and ether. Yields, on nitration, $C_6H_4(NO_2)PO(OH)_2$ [132°], which may be reduced to crystalline $C_6H_4(NH_2).PO(OH)_2$.—NaHA″*x*aq.—Na_2A'' 12aq.—$CaH_2A''_2$.—CaA″ 2aq.—$SrH_2A''_2$aq.—CuA″.—$Fe_2A''_3$ 2½aq.

Ethers.—Me_2A''. (247°).—Et_2A''. (267°).—EtHA″.—EtAgA″.—PhHA″. [57°]. Formed from $C_6H_5POCl_2$ by successive treatment with phenol and boiling water. Needles, sl. sol. water.—Ph_2A''. [63·5°]. Formed from phenol and $C_6H_5PCl_4$.

Chloride $C_6H_5POCl_2$. (258°). Formed from $C_6H_5PCl_4$ and water, and also from $C_6H_5PCl_2$ and O. Thick liquid.

Di-phenyl hydrogen phosphite $(C_6H_5O)_2POH$. Formed by adding a little water to the compound $(C_6H_5O)_2PCl$ (295° at 731 mm.) which is got from phenol and PCl_3 (N.). Uncrystallisable. Decomposed by more water into H_3PO_3 and phenol.

Tri-phenyl phosphite $(C_6H_5O)_3P$. (220° at 11 mm.). S.G. $\frac{15}{15}$ 1·184. Formed by heating phenol (3 mols.) with PCl_3 (1 mol.) at 230° in a current of dry CO_2 (Noack, *A.* 218, 91; Anschütz a. Emery, *A.* 239, 311). Neutral liquid, v. sol. alcohol. Decomposed by water into phenol and H_3PO_3. Dry bromine forms $(C_6H_5O)_3PBr_2$, which is converted by water into $(C_6H_5O)_3PO$.

PHENYL-PHTHALIDE *v. Anhydride* of OXY-BENZYL-BENZOIC ACID.

Di-phenyl-phthalide *i.e.* $C_6H_4<\begin{smallmatrix}CPh_2\\CO\end{smallmatrix}>O$. *Phthalophenone. Tri-phenyl-carbinol carboxylic anhydride.* [115°]. Formed by the action of $AlCl_3$ on a mixture of benzene and phthalyl chloride (Friedel a. Crafts, *A. Ch.* [6] 1, 523, Baeyer, *B.* 12, 612; *A.* 202, 50) or of benzene with [1:2] $C_6H_4Bz.CO.OAc$ (Von Pechmann, *B.* 14, 1866). Got also by heating phthalyl chloride with $HgPh_2$ (Noelting, *B.* 17, 387). Plates (from alcohol). Insol. KOHAq, sol. boiling alcoholic potash, but reppd. by acids.

Reference.—DI-AMIDO-DI-PHENYL-PHTHALIDE.

DI-PHENYL-PHTHALIDE CARBOXYLIC ACID *v. Anhydride* of TRI-PHENYL-CARBINOL DI-CARBOXYLIC ACID.

PHENYL-PHTHALIMIDE *v. Phenyl-imide* of PHTHALIC ACID.

PHENYL-PHTHALIMIDINE $C_{14}H_{11}NO$ *i.e.* $C_6H_4<\begin{smallmatrix}CH_2\\CO\end{smallmatrix}>NPh$. [160°]. Got by heating phthalide with aniline at 210° (Hessert, *B.* 10, 1450; 11, 239; Racine, *A.* 239, 88). Formed also by reducing the phenylimide of phthalic acid with tin and HClAq (Graebe, *A.* 217, 305). Plates (from alcohol), v. sl. sol. hot water.

PHENYL-PIPERAZINE *v.* PHENYL-PYRAZINE HEXAHYDRIDE.

PHENYL-PIPERIDINE *v.* PHENYL-PYRIDINE HEXAHYDRIDE.

PHENYL-PROPANE *v.* CUMENE.

Di-phenyl-propane $CH_2(CH_2Ph)_2$. *Di-benzyl-methane.* (290°–300°). Formed by heating di-benzyl ketone with HIAq and P at 180° (Graebe, *B.* 7, 1623). Got also from $CH_2Cl.CHCl.CH_2Cl$, benzene, and $AlCl_3$ (Claus, *B.* 18, 2935). Liquid.

Di-phenyl-propane $CH_2Ph.CHPh.CH_3$. (291°–295°). S.G. $\frac{0}{0}$ ·996. Formed from benzene, $AlCl_3$, and propylene chloride or allyl chloride (Silva, *C. R.* 89, 606). Formed also by adding H_2SO_4 to a cooled mixture of toluene and styrene (Kraemer, Spilker, a. Ebenhardt, *B.* 23, 3274). Oil, sol. alcohol and ether.

Di-phenyl-propane CMe_2Ph_2. (282°). Formed by the action of benzene and $AlCl_3$ on CCl_2Me_2 or $CH_2{:}CCl.CH_3$ (Silva, *Bl.* [2] 34, 674; 35, 289).

Tri-phenyl-propane $C_3H_5(C_6H_5)_3$. (340°). Formed by the action of $AlCl_3$ upon a mixture of benzene and glyceryl tri-bromide or tri-chloride (Claus a. Mercklin, *B.* 18, 2935). Oil.

PHENYL-PROPANE TRICARBOXYLIC ACID $CH_2Ph.C(CO_2H)_2.CH_2.CO_2H$. [168·5°]. Formed from benzyl-malonic ether, NaOEt, and chloro-acetic ether (Fittig, *A.* 256, 92).

Small prisms, m. sol. warm water. Yields benzyl-succinic acid [161°] when boiled with water.—$Ca_3A'''_2$ 6½aq.—$Ba_3A'''_2$ 2½aq.—Ag_3A'''.

Ethyl ether Et_3A'''. (336° cor.). S.G. $\frac{20}{4}$ 1·1079. $\mu_D = 1{\cdot}484$ at 20°. Formed from sodium ethane tricarboxylic ether and benzyl chloride (Bischoff a. Mintz, *B.* 23, 653).

Di-phenyl-propane tetra-carboxylic acid. *Di-nitrile of the di-ethyl ether* $(CO_2Et)_2C(CH_2.C_6H_4.CN)_2$. [86°]. Formed from sodium malonic ether and $[1:2]C_6H_4(CN).CH_2Cl$ (Hausmann, *B.* 22, 2019). Prisms.

Tri-phenyl-propane dicarboxylic acid.

Imide $C_6H_4{<}\begin{matrix}C(C_7H_7)_2\\CO.NH\end{matrix}{>}CO$. [174°]. Formed from $C_6H_4{<}\begin{matrix}CH_2.CO\\CO\ .NH\end{matrix}$, benzyl chloride, and NaOEt (Pulvermacher, *B.* 20, 2193). Yellow plates (from alcohol).

Benzyl-imide $C_{30}H_{25}NO_2$. [109°].

PHENYL PROPARGYL OXIDE C_9H_8O *i.e.* $C_6H_5.O.C_3H_3$. (210°). S.G. $\frac{0}{0}$ 1·216. Formed by the action of alcoholic potash on the bromo-allyl derivative of phenol (Henry, *C. R.* 96, 1233). Liquid.

PHENYL-PROPARGYL-UREA $C_{10}H_{10}N_2O$ *i.e.* $CH{:}C.CH_2.NH.CO.NHPh$. [133°]. Formed from propargylamine oxalate, phenyl cyanate, and K_2CO_3Aq (Paal a. Hempel, *B.* 24, 3012). Needles.

PHENYL-PROPENYL-AMIDINE $C_9H_{12}N_2$. [98°]. Formed from propionitrile, HCl, and aniline (Michael a. Wing, *Am.* 7, 72). Hexagonal plates, sol. alcohol and ether.—$B'_2H_2PtCl_6$.

PHENYL PROPENYL METHYL KETONE CARBOXYLIC ACID $C_{12}H_{12}O_3$ *i.e.* $CH_3.CO.C(CH_2.CO_2H){:}CHPh$. [125°]. S. 3 at 100°; ·5 at 15°. Formed by boiling benzoic aldehyde with acetyl-propionic acid and NaOAc (Erdmann, *A.* 254, 187).—$BaA'_2$5aq.—$CdA'_2$2aq.—MgA'_2.—$CaA'_2$3½aq: groups of needles.

Methyl ether MeA'. (c. 215° at 38 mm.).

PHENYL PROPENYL SULPHIDE $C_6H_5.S.CMe{:}CH_2$. (208°). Formed by heating phenyl-sulphydro-crotonic acid (Autenrieth, *A.* 254, 232). Yellowish oil, volatile with steam.

TRI-PHENYL PROPENYL TRISULPHONE $C_3H_5(SO_2Ph)_3$. [226°]. Got from $CHBr(CH_2Br)_2$ and sodium benzene sulphinate (Stuffer, *B.* 23, 1413). Needles, m. sol. hot alcohol.

DI-PHENYL-PROPENYL-DI-UREA

$CEt{\lessgtr}\begin{matrix}N\ .CO.NHPh\\NH.CO.NHPh\end{matrix}$. [170°]. Formed from propionamidine and phenyl cyanate (Pinner, *B.* 23, 2924). Needles, m. sol. alcohol. Yields di-phenyl-urea [234°] when boiled for a long time with alcohol. Boiling dilute HOAc forms $NHPh.CO.NH.CO.C_2H_5$ [137°].

PHENYL-PROPIOLIC ACID $C_9H_6O_2$ *i.e.* $C_6H_5.C{:}C.CO_2H$. Mol. w. 146. [137°].

Formation.—1. By the action of Na and CO_2 on ω-bromo-styrene (Glaser, *Z.* [2] 4, 328; *A.* 154, 140).—2. By boiling αβ-di-bromo-phenyl-propionic acid or its ether with alcoholic potash (G.; Perkin, jun., *C. J.* 45, 173; Weger, *A.* 221, 70; Roser, *A.* 247, 138).—3. By boiling α-bromo-cinnamic acid with alcoholic potash (G.; Bairisch, *J. pr.* [2] 20, 181).

Properties.—Trimetric twin crystals. Reduced by zinc and HOAc to cinnamic acid (Aronstein a. Hollemann, *B.* 22, 1181) and by sodium-amalgam to phenyl-propionic acid. Dry HCl passed through its solution in HOAc forms two chloro-cinnamic acids [142°] and [132°] (Michael, *J. pr.* [2] 40, 63).

Salts.—KA'.—BaA'_2aq: square tables.—$BaA'_2$2aq: needles.—$BaA'_2$3aq.—$CuA'_2$4aq.—AgA': sparingly soluble pp.

Ethyl ether EtA'. (260°-270°).

References.—AMIDO- and NITRO- PHENYL-PROPIOLIC ACID.

α-PHENYL-PROPIONIC ACID $C_9H_{10}O_2$ *i.e.* $CH_3.CHPh.CO_2H$. *Hydratropic acid.* (268°). Formed by reducing atropic acid (15 g.) with (5 p.c.) sodium-amalgam (90 g.) (Trinius, *A.* 227, 262; *cf.* Kraut, *A.* 148, 244; Fittig, *A.* 195, 165). Got also from acetophenone by treatment with HCy, the resulting $CH_3.CPh(OH).CN$ being saponified and the oxy-phenyl-propionic acid reduced by HI and P (Janssen, *A.* 250, 135). Oil, with characteristic odour. Yields atrolactic acid $CH_3.CPh(OH).CO_2H$ on oxidation by alkaline $KMnO_4$.—$BaA'_2$2aq.—$CaA'_2$3aq.—$CaA'_2$2aq.—AgA': plates (from hot water).

Methyl ether MeA'. (221°).

Ethyl ether EtA'. (230°). S.G. $\frac{20}{4}$ 1·0147. R_∞ = 83·3 (Brühl).

Amide $CHMePh.CONH_2$. [92°]. Plates.

Nitrile CHMePh.CN. (232°). Formed by the action of PCl_5 on the amide, and from sodium phenyl-acetonitrile and MeI (Oliveri, *G.* 18, 572).

β-Phenyl-propionic acid $CH_2Ph.CH_2.CO_2H$. *Hydrocinnamic acid.* Mol. w. 150. [48·7°]. (280° i.V.). H.C.v. 1,084,600. H.C.p. 1,085,500. H.F. 105,500 (Stohmann, *J. pr.* [2] 40, 135). S. ·6 at 20°. A product of the putrefaction of albumen, 20 g. being got from 5 kilos of ox-brain (Stöckly, *J. pr.* [2] 24, 17).

Formation.—1. By reduction of cinnamic acid by sodium-amalgam or HI (Erlenmeyer, *A.* 121, 375; 137, 327; Popoff, *Bl.* [2] 4, 375; Giacosa, *H.* 8, 108).—2. By reducing αβ-di-bromo-phenyl-propionic acid (Schmitt, *A.* 127, 319).—3. From ethyl-benzene *viâ* $CH_2Ph.CH_2Cl$ and $CH_2Ph.CH_2.CN$ (Fittig, *Z.* 1869, 166; *A.* 156, 249).—4. By oxidising phenyl-propyl alcohol (W. von Miller, *B.* 9, 274).—5. By heating benzyl-malonic acid (Conrad, *A.* 204, 176).

Properties.—Needles (from water), sol. alcohol and ether; volatile with steam. When taken internally it is secreted as hippuric acid (E. a. H. Salkowski, *B.* 12, 653).

Salts.—NH_4A'. Plates, v. e. sol. water.—CaA'_2 1½aq.—$CaA'_2$2aq.—$BaA'_2$2aq.—PbA'_2aq. ZnA'_2.—AgA'. Phenyl-hydrazine salt: [57°]; silky needles (Liebermann, *B.* 24, 1107).

Methyl ether MeA'. (239° cor.). S.G. $\frac{0}{0}$ 1·0455. S.V. 196·0. Liquid, with peculiar odour.

Ethyl ether EtA'. (248° cor.). S.G. $\frac{0}{0}$ 1·0343. S.V. 221·5 (Lossen, *A.* 254, 63).

n-Propyl ether PrA'. (262° cor.). S.G. $\frac{0}{0}$ 1·0152 (Weger, *A.* 221, 79). S.V. 246.

Isoamyl ether $C_5H_{11}A'$. (292°). S.G. $\frac{0}{0}$ ·981; ^{49} ·952 (E.).

Benzyl ether C_7H_7A'. (c. 300°). S.G. $\frac{21}{17{\cdot}5}$ 1·074. Formed by warming benzyl acetate with sodium (Conrad a. Hodgkinson, *B.* 10, 254; *A.* 193. 300).

Amide $C_9H_{11}NO$. [105°]. Formed by heating the ammonium salt at 230° (Hofmann, *B.* 18, 2740). Small needles.

Nitrile C_9H_9N. (261° cor.). S.G. $\frac{15}{15}$ 1·0014.

Occurs in the oil of *Nasturtium officinale* (Hofmann, *B.* 7, 520).

Di-α-phenyl-propionic acid $CH_3.CPh_2.CO_2H$. [178°]. (above 300°). Made by oxidation of the (β)-pinacolin of acetophenone $CPh_2Me.CO.CH_3$ [41°] with chromic acid mixture (Thörner a. Zincke, *B.* 11, 1993). Formed also by dissolving pyruvic acid and benzene in H_2SO_4 at 0° (Böttinger, *B.* 14, 1595). White leaflets, sol. ether, alcohol, and hot water.—KA′—CaA′$_2$ 1½aq.—BaA′ 2aq.—AgA′: white pp.

αβ-Di-phenyl-propionic acid $CH_2Ph.CHPh.CO_2H$. [84°]. Formed by the action of sodium-amalgam on a mixture of benzyl chloride and $ClCO_2Et$ (Wurtz, *C. R.* 70, 350). Got also by reducing phenyl-cinnamic acid (Oglialoro, *J.* 1878, 821). Needles, sl. sol. boiling water.—CaA′$_2$.—PbA′$_2$. [146°].—AgA′.

Nitrile $CH_2Ph.CHPh.CN$. [58°]. (c. 335°) (Janssen, *A.* 250, 133).

Di-β-phenyl-propionic acid $CHPh_2.CH_2.CO_2H$. [145°]. Formed from allo-cinnamic acid, benzene, and H_2SO_4 (Liebermann a. Hartmann, *B.* 25, 960). Needles.—CaA′$_2$.

ααβ-Tri-phenyl-propionic acid $CH_2Ph.CPh_2.CO_2H$. [162°]. Formed by saponifying the nitrile with HOAc and fuming HClAq at 220° (Neure, *A.* 250, 147). White needles, v. sl. sol. water.—AgA′: white insoluble powder.

Nitrile $CH_2Ph.CPh_2.CN$. [126°]. Formed from $CHPh_2.CN$, benzyl chloride, and NaOEt.

Tri-β-phenyl propionic acid $Ph_3C.CH_2.CO_2H$. [177°]. Formed from $Ph_3C.CH(CO_2Et)_2$ by boiling with alcoholic potash (Henderson, *C. J.* 51, 226; *B.* 20, 1014). Prisms (from alcohol), v. sl. sol. water.—KA′aq.—NaA′aq.—BaA′$_2$aq.—AgA′. Minute needles.

Ethyl ether EtA′. [81°].

References.—AMIDO-, AMIDO-SULPHO-, BROMO-, BROMO-SULPHO-, BROMO-AMIDO-, BROMO-NITRO-, CHLORO-, IODO-, IODO-OXY-, NITRO-AMIDO-, NITRO-OXY-, NITRO-, OXY-AMIDO- and OXY- PHENYL-PROPIONIC ACID.

PHENYL-PROPIONIC ALDEHYDE $C_6H_5.CH_2.CH_2.CHO$. [208°]. Formed from *n*-cumene by successive treatment with CrO_2Cl_2 and water (Étard, *A. Ch.* [5] 22, 254). Oil. Forms a crystalline compound with $NaHSO_3$.

Oxim. Oil. Yields a solid hydrochloride. Ac_2O rapidly forms phenyl-propionitrile; hence it is a *syn-* oxim (Dollfus, *B.* 25, 1918).

PHENYL-PROPYL ALCOHOL $C_9H_{12}O$ *i.e.* $CHPhEt.OH$. Mol. w. 136. (216°). S.G. ^{0} 1·016. Formed by reducing phenyl ethyl ketone with sodium-amalgam (Errera, *G.* 16, 322; *cf.* Barry, *B.* 6, 1007. Got also from benzoic aldehyde by successive treatment with $ZnEt_2$ and water (Wagner, *Bl.* [2] 42, 330). Yields $CHPhEt.OAc$ (228° i.V.) and oily $CHPhEtCl$.

Phenyl-propyl alcohol $CH_2Ph.CH_2.CH_2OH$. (235° uncor.) (213° at 360 mm.). S.G. $\frac{20}{4}$ 1·0079. μ_β 1·5478. $R_\infty = 68·79$ (Brühl, *A.* 200, 191). Occurs in storax as phenyl-propyl cinnamate (Miller, *A.* 188, 202). Prepared by reducing cinnamyl alcohol with sodium-amalgam (Rügheimer, *B.* 6, 214; *A.* 172, 123; Hatton a. Hodgkinson, *C. J.* 39, 319; Errera, *G.* 16, 310). Viscid oil. Heating with conc. HClAq yields $CH_2Ph.CH_2.CH_2Cl$ (219°), whence NaOEt forms $CH_2Ph.CH_2.CH_2OEt$ (220°).

Acetyl derivative $C_3H_6Ph.OAc$. (245°).

Phenyl-isopropyl alcohol $CH_2Ph.CH(OH).CH_3$. *Methyl-benzyl-carbinol.* (215°). Got by reducing benzyl methyl ketone (E.). Liquid, with pleasant odour.

Di-phenyl-propyl alcohol $CH_2Ph.CHPh.CH_2OH$. (301°). Formed by warming di-phenyl-propylamine nitrite (Freund a. Remse, *B.* 23, 2863). Oil, sol. alcohol.

PHENYL-PROPYL-AMINE $C_9H_{13}N$ *i.e.* $CH_2Ph.CH_2.CH_2NH_2$. (222° i.V.). Formed by reducing the phenyl-hydrazide (20 g.) of cinnamic aldehyde dissolved in alcohol (300 g.) by (2½ p.c.) sodium-amalgam (700 g.) and HOAc (70 g.) at about 30°, the yield being 30 p.c. of the theoretical (Tafel, *B.* 19, 1930; 22, 1857). Liquid, m. sol. water, miscible with alcohol and ether. Absorbs CO_2 from air, forming a crystalline mass. The aqueous solution is strongly alkaline.—B′HCl. [218°]. Plates.—B′H_2SO_4.—B′$_2H_2C_2O_4$. [156°]. Needles.—B′$H_2C_2O_4$.—B′$_2H_2PtCl_6$. Plates, sol. hot water.

Phenyl-isopropyl-amine $CH_2Ph.CHMe.NH_2$. (203°). Formed by the action of Br and KOHAq on the amide of phenyl-isobutyric acid (Edeleano, *B.* 20, 618). Liquid.—B′$_2H_2PtCl_6$. Needles.

Isomeride *v.* CUMIDINE.

Di-phenyl-propyl-amine $CH_2Ph.CHPh.CH_2NH_2$. (316°). Formed by reducing the nitrile (30 g.) of phenyl-cinnamic acid dissolved in alcohol by treatment with Na (75 g.) (Freund a. Remse, *B.* 23, 2860). Liquid, sol. alcohol. Forms with $HgCl_2$ a crystalline compound [107°].—B′HCl. [190°]. Needles.—Aurochloride [145°].

Di-acetyl derivative. [85°]. Needles.

PHENYL-*n*-PROPYL-TRIAZOLE CARBOXYLIC ACID

$\left.\begin{array}{l}\text{N.NPh}\\ \text{CPr.N}\end{array}\right\rangle\text{C.CO}_2\text{H}$. [161°].

Formed by saponifying the nitrile which is made from phenyl-hydrazine dicyanide and butyric anhydride (Bladin, *B.* 25, 179). Cubes (from alcohol) or prisms (from benzene).—CuA′$_2$ ½aq.—AgA′. Bulky white pp.

Amide $C_2N_3PhPr.CO.NH_2$. [122·5°]. The thio-amide $C_2N_3PhPr.CS.NH_2$ [130·5°] is got by the action of alcoholic ammonium sulphide on the nitrile.

Phenyl-isopropyl-triazole carboxylic acid

$\left.\begin{array}{l}\text{N.NPh}\\ \text{CPr.N}\end{array}\right\rangle\text{C.CO}_2\text{H}$. [155°]. Formed in like manner (B.). Prisms.—HA′HCl. Needles.—CuA′$_2$ 2½aq.—AgA: minute tables.

Methyl ether MeA′. [76°].

Amide. [128°]. Needles. The thio-amide $C_2N_3PhPr.CS.NH_2$ [148°], formed by the action of alcoholic NH_3 and H_2S on the crude nitrile, crystallises in yellow needles.

DI-PHENYL-DI-ISOPROPYL-TETRAZONE $NPhPr.N{:}N.NPhPr$. [79°]. Formed by oxidising phenyl-isopropyl-hydrazine with HgO (Michaelis a. Philips, *A.* 252, 281). Octahedra.

DI-PHENYL-PROPYL TRICYANIDE

$\text{CPh}\left\langle\begin{array}{l}\text{N.CPr}\\ \text{N:CPh}\end{array}\right\rangle\text{N}$. [78·5°]. (239° at 15 mm.).

Formed from benzonitrile, butyryl chloride, and $AlCl_3$ at 75° (Krafft a. Von Hansen, *B.* 22, 807). Decomposed by dilute H_2SO_4 into NH_3, butyric acid, and HOBz.—B′$_2H_2PtCl_6$. Needles.

PHENYL-PROPYLENE *v.* ALLYL-BENZENE.

PHENYL PROPYLENE - ψ - THIO - UREA $C_{10}H_{12}N_2S$ *i.e.*  $\left.\begin{matrix}\mathrm{CHMe.S}\\ \mathrm{CH_2.N}\end{matrix}\right>\mathrm{C.NHPh}$. [117°]. Formed from the isomeric phenyl-allyl-thio-urea [95°] and HClAq at 100° (Prager, *B.* 22, 2992). Oxidised by potassium chlorate and HClAq to  $\left.\begin{matrix}\mathrm{CHMe.SO_3}\\ \mathrm{CH_2{-}{-}{-}N}\end{matrix}\right>\mathrm{C.NHPh}$ [192°]. — $B'_2H_2PtCl_6$. — $B'C_6H_3N_3O_7$. [154°]. Yellow needles.

DI - PHENYL - ISOPROPYL - GLYOXALINE TETRA - HYDRIDE  $\mathrm{CHPr}\left<\begin{matrix}\mathrm{NPh.CH_2}\\ \mathrm{NPh.CH_2}\end{matrix}\right.$. [95°]. Formed from di-phenyl-ethylene-diamine and isobutyric aldehyde (Moos, *B.* 20, 734). Crystalline groups (from alcohol), sl. sol. water.

PHENYL-PROPYL-HYDRAZINE $C_9H_{14}N_2$ *i.e.* $C_6H_5NH.NHPr$. [158°]. Formed by heating propionamide with phenyl-hydrazine (Freund, *B.* 21, 2461). Plates (from chloroform).

Phenyl-isopropyl-hydrazine $C_6H_5NPr.NH_2$. (233°). Formed from sodium phenyl-hydrazine and isopropyl bromide (Michaelis a. Philips, *B.* 20, 2485; *A.* 252, 278). – B'HCl. [135°]. Crystalline. Yields a tetrazone [85°]. Phenyl-thio-carbimide forms NPhPr.NH.CS.NHPh. [116°].

Acetyl derivative. [102°]. Needles.

DI-PHENYL-PROPYLIDENE DISULPHIDE $Me_2C(SPh)_2$. [56°]. Formed from phenyl-mercaptan and acetone (E. Baumann, *B.* 19, 2804). Crystals, insol. water, v. sol. alcohol.

DI-PHENYL-PROPYLIDENE DISULPHONE $Me_2C(SO_2Ph)_2$. [97°] (B.); [182°] (F.). Formed by oxidising $Me_2C(SPh)_2$ (Baumann, *B.* 19, 2810), and also by treating $CH_2(SPh)_2$ with NaOH and MeI (Fromm, *A.* 253, 162). Crystals, almost insol. cold water.

PHENYL PROPYL KETONE $C_{10}H_{12}O$ *i.e.* Ph.CO.Pr. Mol. w. 148. (221°). S.G. ^{15} ·992.

Formation. – 1. By distilling calcium butyrate with calcium benzoate (Schmidt a. Fieberg, *B.* 6, 498).—2. By the action of $AlCl_3$ on a mixture of benzene and butyryl chloride (Burcker, *Bl.* [2] 37, 4).—3. By boiling benzoyl-acetic acid with dilute alcoholic potash (Baeyer a. Perkin, *B.* 16, 2131; *C. J.* 45, 181).

Properties. — Oil. Does not unite with $NaHSO_3$. Oxidised by CrO_3 and H_2SO_4 to benzoic and propionic acids (Popoff, *B.* 6, 560). CrO_2Cl_2 forms $C_{10}H_{12}O2CrO_2Cl_2$, a brown powder.

Phenyl isopropyl ketone Ph.CO.Pr. (209°–217°). Formed by distilling calcium isobutyrate with calcium benzoate (Popoff, *B.* 6, 1255). Liquid. Yields benzoic acid, CO_2, and HOAc on oxidation.

Oxim.—Ph.C(NOH)Pr. [58°]. Plates (from ligroïn) (Rattner, *B.* 20, 506).

PHENYL PROPYL KETONE CARBOXYLIC ACID *v. Ethyl-benzoyl-acetic acid*, vol. i. p. 482.

Phenyl isopropyl ketone *o*-**carboxylic acid** $C_{11}H_{12}O_3$ *i.e.* $Pr.CO.C_6H_4.CO_2H$. [121°]. Formed by boiling isopropylidene-phthalide with alcohol and KOHAq (Roser, *B.* 17, 2777). Crystals.

PHENYL - PROPYL METHYL KETONE CARBOXYLIC ACID $CH_2Ph.CHAc.CH_2.CO_2H$. [99°]. (235° at 40 mm.). Formed by reducing benzylidene-β-acetyl-propionic acid with sodium-amalgam in presence of H_2SO_4 (Erdmann, *A.* 254, 203). Needles. It yields on oxidation $\mathrm{CHMe}\left<\begin{matrix}\mathrm{CH(C_3H_7)}\\ \mathrm{O\ .\ CO}\end{matrix}\right>\mathrm{CH_2}$ [86°]. — CaA'_2 3aq. — AgA'.

PHENYL METHYLENE PROPYL DI-KETONE *v.* BUTYRYL-ACETOPHENONE.

PHENYL-PROPYL METHYL KETONE $CH_3.CO.CHMe.CH_2Ph$. (239°). Formed by distilling calcium acetate with calcium phenyl-isobutyrate (Von Miller, *B.* 23, 1884). Oil.

PHENYL - PROPYL METHYL KETONE CARBOXYLIC ACID *v.* BENZYL-METHYL-ACETO-ACETIC ACID, vol. i. p. 25.

Di-phenyl-isopropyl methyl ketone tricarboxylic acid. *Ethyl ether of the dinitrile* $CO_2Et.C(CH_2.C_6H_4.CN)_2.CO.CH_3$. [120°]. Formed from sodium acetoacetic ether and the nitrile [1:2] $CH_2Cl.C_6H_4.CN$ (Gabriel a. Hausmann, *B.* 22, 2018). Prisms (from alcohol).

Hexa-phenyl-isopropyl methyl ketone carboxylic acid $C_{42}H_{19}O_4$ *i.e.* $(CPh_3)_2C(CO_2H).CO.CH_3$. [160°]. Formed from sodium acetoacetic ether and $BrCPh_3$ (Allen a. Kölliker, *A.* 227, 111). Crystals (from ether).

PHENYL-PROPYL-PYRAZOLE $C_{12}H_{14}N_2$ *i.e.*  $\mathrm{NPh}\left<\begin{matrix}\mathrm{C(C_3H_7){:}CH}\\ \mathrm{N{=}{=}{=}{=}CH}\end{matrix}\right.$ (280°). S.G. ^{15} 1·0435. Formed from butyryl-acetic aldehyde and phenyl-hydrazine (Claisen a. Stylos, *B.* 21, 1148). Liquid.

PHENYL PROPYL SULPHONE $Ph.SO_2.Pr$. [44°]. Formed by the action of KOHAq at 100° on $Ph.SO_2.CHEt.CO_2H$ [124°], which is made from α-bromo-butyric acid and sodium benzene sulphinate (Michael a. Palmer, *Am.* 7, 67; *cf.* Otto, *B.* 21, 998). Pearly plates, v. sol. alcohol.

TRI - PHENYL - DI - PROPYL - DI - THIO - BIURET $C_2S_2N_3Ph_3Pr_2$. [154°]. Formed by the action of aniline (1 mol.) on NPhPr.CSCl (2 mols.) (Billeter a. Strohl, *B.* 21, 109). Yellow needles.

PHENYL - PROPYL - THIO - CARBAMIC CHLORIDE NPhPr.CS.Cl. [36°]. Formed from propyl-aniline and $CSCl_2$ (Billeter a. Strohl, *B* 21, 102). Prisms (from ligroïn).

DI - PHENYL - ISOPROPYL - THIO - SEMI - CARBAZIDE NHPh.CS.NH.NPhPr. [116°]. Formed from phenyl-thiocarbimide and phenyl-isopropyl-hydrazine (Michaelis a. Philips, *A.* 252, 280). Crystalline.

PHENYL-PROPYL-THIO-UREA $C_{10}H_{14}N_2S$ *i.e.* $NHPh.CS.NHC_3H_7$. [63°]. Formed from aniline and propyl-thio-carbimide and also from propyl-amine and phenyl thiocarbimide (O. Hecht, *B.* 23, 286). Pearly plates (from dilute alcohol).

Di-phenyl-propyl-thio-urea CSN_2HPh_2Pr. [104°]. Formed by heating propyl-aniline with phenyl-thio-carbimide on the water-bath (Billeter a. Strohl, *B.* 21, 109). Needles.

Di-phenyl-di-propyl-thio-urea $CS(NPhPr)_2$. [103°]. Formed from propyl-aniline and $CSCl_2$ (B. a. S.). Large plates.

DI-PHENYL-PROPYL-UREA $C_{16}H_{18}N_2O$ *i.e.* $NH_2.CO.NH.CH_2.CHPh.CH_2Ph$. [112°]. Formed from di-phenyl-propylamine hydrochloride and potassium cyanate solution (Freund a. Remse, *B.* 23, 2861). Needles, sol. alcohol and ether.

PHENYL-PYRAZINE. *Hexahydride*  $\mathrm{NPh}\left<\begin{matrix}\mathrm{CH_2.CH_2}\\ \mathrm{CH_2.CH_2}\end{matrix}\right>\mathrm{NH}$. Formed by heating bromo-benzene (8 pts.) with pyrazine hexahydride (8 pts.) at 270° (Schmidt a. Wichmann, *B.* 24, 3239). Thick liquid, v. sol. water.

Di-phenyl-pyrazine $C_{16}H_{12}N_2$, *i.e.* $\mathrm{N}\!<\!\begin{matrix}\mathrm{CH{:}CPh}\\\mathrm{CPh.CH}\end{matrix}\!>\!\mathrm{N}$. *Iso-indole.* [196° cor.]. V.D. 7·95 (Treadwell a. Meyer, *B.* 16, 342). Formed by the action of cold alcoholic NH_3 on ω-bromo-acetophenone or on amido-acetophenone (Staedel a. Kleinschmidt, *B.* 11, 1744; 13, 837; Möhlau, *B.* 18, 163; Wolff a. Röders, *B.* 20, 432; Goedeckemeyer, *B.* 21, 2687). Broad yellow needles (from alcohol). — $B'_2H_2PtCl_6$. Bronzed plates (from HClAq) quickly decomposed by water.

Hexahydride $C_{16}H_{18}N_2$. [109°] and [123°]. Formed by reducing di-phenyl-pyrazine with Na and isoamyl alcohol. Occurs in two forms. The (α)-variety [123°] crystallises from ligroïn in white needles, and yields $B''2HCl$ [c. 310°], $B''H_2PtCl_6\frac{1}{2}aq$, and a nitrosamine $C_{16}H_{16}N_6O_4$ [143°]. The (β)-variety [109°] crystallises from alcohol in white needles and yields $B''2HCl$ [c. 295°] and $B''H_2PtCl_6 2aq$.

Di-phenyl-pyrazine $\mathrm{N}\!<\!\begin{matrix}\mathrm{CPh.CPh}\\\mathrm{CH:CH}\end{matrix}\!>\!\mathrm{N}$. [119°]. (c. 340°). Formed by distilling the dihydride (M.). Needles (from ligroïn), ppd. by adding water to its solution in HClAq.—$B'_2H_2PtCl_6$.

Dihydride $\mathrm{N}\!<\!\begin{matrix}\mathrm{CPh.CPh}\\\mathrm{CH_2.CH_2}\end{matrix}\!>\!\mathrm{N}$. [181°]. Formed by boiling benzil with ethylene-diamine and alcohol (Mason, *B.* 20, 268; *C. J.* 55, 97). Prisms (from alcohol), insol. water. Split up by HClAq into the parent substances.

Di-phenyl-pyrazine. *Hexahydride v.* DI-PHENYL-DI-ETHYLENE-DIAMINE.

Tetra-phenyl-pyrazine $\mathrm{N}\!<\!\begin{matrix}\mathrm{CPh{:}CPh}\\\mathrm{CPh.CPh}\end{matrix}\!>\!\mathrm{N}$. *Di-tolane-azotide.* [241°] (P.); [247°] (G.). Formed by heating benzoïn with ammonium acetate (vol. i. p. 477). Formed also by reducing the di-oxim of di-phenyl-glyoxal in alcoholic solution by sodium-amalgam (Polonowska, *B.* 21, 489), and by heating benzoic aldehyde with $CPhH(NH_2).CPhH(NH_2)$ (Grossmann, *B.* 22, 2302). White needles (from HOAc), v. sl. sol. alcohol. Conc. H_2SO_4 gives a blood-red colour.

PHENYL-PYRAZOLE $C_9H_8N_2$ *i.e.* $\begin{matrix}\mathrm{NPh.CH}\\\mathrm{N{=}{=}CH}\end{matrix}\!>\!\mathrm{CH}$. [11°]. (247° cor.). S.G. $\frac{18}{0}$ 1·113. Formed by boiling epichlorhydrin with phenyl-hydrazine and benzene (Balbiano, *G.* 17, 176; 18, 354). Got also by distilling its tricarboxylic acid (Knorr a. Laubmann, *B.* 22, 180). Oil, sol. alcohol and ether. — $B'_2H_2PtCl_6 2aq$: needles, decomposing at 175°.

Ethylo-iodide B'EtI. [117°]. Prisms.

Dihydride $\begin{matrix}\mathrm{NPh.CH_2}\\\mathrm{N{=}{=}CH}\end{matrix}\!>\!\mathrm{CH_2}$. [52°]. (274° at 754 mm.). Formed from phenyl-hydrazine (120 g.) dissolved in ether (600 g.) by addition of arcoleïn (50 g.) in ether (100 g.) (Fischer a. Knoevenagel, *A.* 239, 196). Sl. sol. hot water, v. sol. alcohol, ether, and benzene. Sl. sol. dilute acids, sol. conc. HCl. May be distilled with steam. $K_2Cr_2O_7$ colours its solution in dilute H_2SO_4 reddish-violet, or, in very dilute solutions, blue. Gives no indole derivative when fused with $ZnCl_2$.

Reference. — DI-BROMO-PHENYL-PYRAZOLE DIHYDRIDE.

Tetra-hydride $\begin{matrix}\mathrm{NPh.CH_2}\\\mathrm{NH.CH_2}\end{matrix}\!>\!\mathrm{CH_2}$. (210° at 165 mm.). Formed from tri-methylene bromide, sodium phenyl-hydrazine, and benzene (Michaelis a. Lampe, *B.* 24, 3738). Liquid. — $B'C_6H_3N_3O_7$. Short yellow needles.

Di-phenyl-pyrazole $C_{15}H_{12}N_2$ *i.e.* $\begin{matrix}\mathrm{CH{:}CH}\\\mathrm{CPh{:}N}\end{matrix}\!>\!\mathrm{NPh}$ or $\begin{matrix}\mathrm{CH{:}CPh}\\\mathrm{CH{:}N}\end{matrix}\!>\!\mathrm{NPh}$. [56°]. (336°). Formed by distilling its carboxylic acids (Beyer a. Claisen, *B.* 20, 2187; Knorr a. Laubmann, *B.* 21, 1212; 22, 176). White crystals.

Dihydride $C_{15}H_{14}N_2$. [136°]. Formed by reducing the base. Small needles. An isomeric or identical body [138°], got by distilling the phenyl-hydrazide of cinnamic aldehyde; differs by fluorescing slightly in alcoholic solution.

Tri-phenyl-pyrazole $C_{21}H_{16}N_2$. [206°]. A product of the action of phenyl-hydrazine on anhydro-acetophenone-benzil (Japp a. Klingemann, *C. J.* 57, 709). Stellate groups of needles.

Tri-phenyl-pyrazole $\begin{matrix}\mathrm{CH{:}CPh}\\\mathrm{CPh{:}N}\end{matrix}\!>\!\mathrm{NPh}$. [138°]. Got by warming CH_2Bz_2 with phenyl-hydrazine (Knorr a. Laubmann, *B.* 21, 1205). Plates (from ether). Weak base.

Methylo-iodide B'MeI. [176°].

Dihydride $\begin{matrix}\mathrm{CH_2.CHPh}\\\mathrm{CPh{-}{-}N}\end{matrix}\!>\!\mathrm{NPh}$. [135°]. Got by reduction or by warming benzylidene-acetophene with phenyl-hydrazine and alcohol. Yields $C_{21}H_{15}Br_4N_2$ [179°].

PHENYL-PYRAZOLE CARBOXYLIC ACID $C_{10}H_8N_2O_2$. [220°]. Formed by distilling the tricarboxylic acid (Knorr a. Laubmann, *B.* 22, 180). Needles (from Aq), v. sol. alcohol, sl. sol. ether. May be sublimed. AgA': amorphous pp.

Phenyl-pyrazole dicarboxylic acid $\begin{matrix}\mathrm{C(CO_2H){:}N}\\\mathrm{CH{:}C(CO_2H)}\end{matrix}\!>\!\mathrm{NPh}$. [256°] (B.); [266°] (C. a. R.). Formed by oxidising phenyl-di-methyl-pyrazole or phenyl-methyl-pyrazole carboxylic acid with alkaline $KMnO_4$ (Balbiano, *B.* 23, 1449; Claisen a. Roosen, *B.* 24, 1892). Small white plates in spherical groups (from alcohol). — $(NH_4)_2A''$. [212°].—PbA''.—Ag_2A''.

Methyl ether MeA''. [128°].

Amide $C_3N_2HPh(CO.NH_2)_2$. [190°].

Phenyl-pyrazole tri-carboxylic acid $\begin{matrix}\mathrm{CO_2H.C{=}{=}N}\\\mathrm{CO_2H.C{:}C(CO_2H)}\end{matrix}\!>\!\mathrm{NPh}$. [184°]. Formed by oxidising phenyl-methyl-pyrazole dicarboxylic acid with alkaline $KMnO_4$ (K. a. L.). White needles (containing aq) (from ether), sol. water and alcohol.—$BaHA'''\frac{1}{2}aq$: plates.

Di-phenyl-pyrazole carboxylic acid $C_{16}H_{12}N_2O_2$ *i.e.* $\begin{matrix}\mathrm{CPh{=}{=}N}\\\mathrm{CH{:}C(CO_2H)}\end{matrix}\!>\!\mathrm{NPh}$ or $\begin{matrix}\mathrm{CO_2H.C{=}{=}N}\\\mathrm{CH{:}CPh}\end{matrix}\!>\!\mathrm{NPh}$. Got by saponification of its ether, which is obtained by boiling benzoyl-pyruvic ether $CH_2Bz.CO.CO_2Et$ (20 pts.) with HOAc (100 pts.) and phenyl-hydrazine (10 pts.) (Beyer a. Claisen, *B.* 20, 2185). Crystals (containing EtOH), which melt at 185°, v. sol. acetone.

Ethyl ether EtA'. [90°]. (c. 400°).

Di-phenyl-pyrazole dicarboxylic acid $C_{17}H_{12}N_2O_4$ *i.e.* $\begin{matrix}\mathrm{CPh{=}N}\\\mathrm{CO_2H.C.C(CO_2H)}\end{matrix}\!>\!\mathrm{NPh}$. [218°]. Got by oxidation of di-phenyl-methyl-pyrazole carboxylic acid (Knorr a. Laubmann, *B.* 22, 175). Satiny needles (containing $\frac{1}{2}$ aq) (from HOAc).—NH_4HA''. [c. 270°].—BaA'' aq.—CaA'' 2aq.

References.—OXY- and OXY-AMIDO- PHENYL-PYRAZOLE CARBOXYLIC ACID.

DI-PHENYL-PYRAZOLONE *v.* OXY-DI-PHENYL-PYRAZOLE.

PHENYL-PYRAZYL METHYL KETONE $C_3N_2H_2Ph.CO.CH_3$. [122° cor.]. Formed by heating ν-phenyl-pyrazole with AcCl at 150° (Balbiano, *G.* 19, 136). Small needles. Yields an oxim [131°] and a phenyl-hydrazide [144°].

TETRA-PHENYL-PYRIDAZINE DIHYDRIDE $C_{28}H_{22}N_2$ *i.e.*

$\begin{matrix}\mathrm{CH_2.CPh{:}N}\\ \mathrm{CPh{:}CPh.NPh}\end{matrix}$

? [149°]. Formed from desyl-acetophenone, phenyl-hydrazine, and HOAc (Smith, *C. J.* 57, 649). Yellow needles (from alcohol), v. sol. hot HOAc. According to Klingemann (*A.* 269, 106), this body is probably phenyl-amido-tri-phenyl-pyrrole, since on boiling with HOAc it yields tetra-phenyl-pyrrole.

(α)-PHENYL-PYRIDINE

$\mathrm{N}\left<\begin{matrix}\mathrm{CPh.CH}\\ \mathrm{CH{:}CH}\end{matrix}\right>\mathrm{CH}$.

(270°). A product of the distillation of its di-carboxylic acid with lime (Skraup a. Cobenzl, *M.* 4, 472). Heavy oil. Yields picolinic acid on oxidation.—$B'_2H_2PtCl_6$ 2aq.—Picrate [c. 170°].

(β)-Phenyl-pyridine

$\mathrm{N}\left<\begin{matrix}\mathrm{CH.CPh}\\ \mathrm{CH{:}CH}\end{matrix}\right>\mathrm{CH}$.

(270°). Formed by distilling its carboxylic acid with lime (Skraup a. Cobenzl, *M.* 4, 453). Got also by heating pyrrole with benzylidene chloride and NaOEt (Ciamician a. Silber, *B.* 20, 191). Heavy oil. Yields nicotinic acid on oxidation. — $B'_2H_2PtCl_6$ 3aq. — $B'C_6H_3N_3O_7$. [163°]. Groups of yellow needles.

(γ)-Phenyl-pyridine

$\mathrm{N}\left<\begin{matrix}\mathrm{CH.CH}\\ \mathrm{CH{:}CH}\end{matrix}\right>\mathrm{CPh}$.

[78°]. (275° uncor.). Formed by distilling its tetra-carboxylic acid with lime (Hantzsch, *B.* 17, 1518). Plates (from water). Yields iso-nicotinic acid [304°] on oxidation.—$B'_2H_2PtCl_6$.—$B'_2H_2Cr_2O_7$. [155°]. Orange needles. — Picrate. [196°]. Yellow needles.

Hexahydride $C_5H_{10}PhN$. [58°]. (256° at 727 mm.). Got by reducing the base (Bally, *B.* 20, 2590). Strong base, almost insol. water.—B'HCl. Needles.—$B'_2H_2PtCl_6$. [204°–207°].

ν-Phenyl-pyridine hexahydride

$\mathrm{NPh}\left<\begin{matrix}\mathrm{CH_2.CH_2}\\ \mathrm{CH_2.CH_2}\end{matrix}\right>\mathrm{CH_2}$.

Phenyl-piperidine. (249°). Formed by heating piperidine with iodo-benzene or bromo-benzene at 260° (Lellmann, *B.* 20, 680; 21, 2279. Alkaline oil, v. sol. alcohol and ether.—$B'_2H_2PtCl_6$ 2aq: needles or plates.—$B'H_2Cr_2O_7$: plates.

References.—AMIDO- and NITRO- PHENYL-PIPERIDINE.

Di-(α)-phenyl-pyridine $C_{17}H_{13}N$ *i.e.*

$\mathrm{N}\left<\begin{matrix}\mathrm{CPh{:}CH}\\ \mathrm{CPh.CH}\end{matrix}\right>\mathrm{CH}$.

[82°] (P. a. S.); [73°] (D.). Formed by distilling its carboxylic acids with soda-lime (Paal a. Strasser, *B.* 20, 2764; Doebner, *A.* 249, 121). Yellow needles, v. sol. alcohol. Yields an oily hexahydride.—$B'_2H_2PtCl_6$. [205°].—$B'HAuCl_4$. [202°].—$B'_4H_4Cr_3O_{11}$. Orange-red needles.

Methylo-iodide B'MeI. [203°].

Tri-phenyl-pyridine $C_{23}H_{17}N$. [135°]. Formed by passing NH_3 through acetophenone, and adding P_2O_5 (Engler, *B.* 6, 639; 19, 40; *A.* 238, 27).—$B'_2H_2PtCl_6$.

Reference.—OXY-PHENYL-PYRIDINE.

PHENYL-PYRIDINE *o*-CARBOXYLIC ACID $C_{12}H_9NO_2$ *i.e.*

$\mathrm{N}\left<\begin{matrix}\mathrm{CH{:}C(C_6H_4.CO_2H)}\\ \mathrm{CH.CH{=\!=\!=}CH}\end{matrix}\right>$.

[185°]. Formed by heating the dicarboxylic acid at 185° (Skraup a. Cobenzl, *M.* 4, 450). Needles, sl. sol. cold water. Yields nicotinic acid on oxidation.—CaA'_2 2aq: long needles, v. sol. cold water.

(α)-Phenyl-pyridine dicarboxylic acid $C_{13}H_9NO_4$ *i.e.*

$\mathrm{N}\left<\begin{matrix}\mathrm{C(C_6H_4.CO_2H){:}C.CO_2H}\\ \mathrm{CH{-\!-\!-}CH{:}CH}\end{matrix}\right.$

[230°–235°]. Formed by oxidation of (α)-naphtho-quinoline (Skraup a. Cobenzl, *M.* 4, 463). Minute crystals, gives off indigo-blue vapours when heated. When distilled with CaO it yields (α)-phenyl-pyridine and the compound $C_{12}H_7NO$ [140°–142°] (315°), which crystallises from alcohol in yellow plates and yields $B'_2H_2PtCl_6$. Yields a di-bromo- derivative [205°].

Salts. — CaA″ 2aq. — CuA″ 4aq: violet crystalline pp. — Ag_2A'' 1½aq. — H_2A''HCl. — $(H_2A'')_2H_2PtCl_6$ 3aq.

(β)-Phenyl-pyridine dicarboxylic acid

$\mathrm{N}\left<\begin{matrix}\mathrm{C(CO_2H){:}C.C_6H_4.CO_2H[1{:}2]}\\ \mathrm{CH.CH{:}CH}\end{matrix}\right.$

. [207°]. Formed by oxidation of (β)-naphthoquinoline (Skraup a. Cobenzl, *M.* 4, 442). Prisms (containing aq), sl. sol. cold water. Salts. — HA′HCl. — $(HA')_2H_2PtCl_6$ 2½aq. — K_2A'' 3aq. — KHA″ 2aq. — CaA″ 3aq. BaA″ 4½aq. — CuA″ 4aq. — $Cu_2H_2A''_3$. —$AgH_3A''_2$.

Sulphonic acid $C_{13}H_9NSO_7$ *i.e.*

$\mathrm{N}\left<\begin{matrix}\mathrm{C(CO_2H){:}C.C_6H_3(SO_3H)(CO_2H)[1{:}2{:}6]}\\ \mathrm{CH.CH{:}CH}\end{matrix}\right.$.

Formed, as well as $C_{12}H_8(SO_3H)NO$ aq, by oxidation of (β)-naphtho-quinoline sulphonic acid with alkaline $KMnO_4$ (Immerheiser, *B.* 22, 405). Crystals (from water). — K_3A'''. — $Ba_3H_3A'''_3$.— $Pb_4A'''_2(OH)_2$. — Ag_3A''' (dried at 100°).

The by-product $C_{12}H_8(SO_3H)NO$ aq yields KA′ aq, BaA'_2 2aq, PbA'_2 3aq, AgA′ aq, an oxim [290°] and a phenyl-hydrazide [c. 295°].

Phenyl-pyridine dicarboxylic acid

$\mathrm{N}\left<\begin{matrix}\mathrm{CH{:}C(CO_2H)}\\ \mathrm{CH.C(CO_2H)}\end{matrix}\right>\mathrm{CPh}$.

[230°] (hydrated); [246°] (anhydrous). Formed by heating the tetra-carboxylic acid at 170° (Weber, *A.* 241, 13). Greenish-yellow plates (containing aq). — CuA″ 2aq: blue pp.

(γ)-Phenyl-pyridine tetra-carboxylic acid

$\mathrm{N}\left<\begin{matrix}\mathrm{C(CO_2H).C(CO_2H)}\\ \mathrm{C(CO_2H).C(CO_2H)}\end{matrix}\right>\mathrm{CPh}$.

[207°]. Formed by oxidation of the phenyl-di-methyl-pyridine dicarboxylic acid, which is got from acetoacetic ether, NH_3, and benzoic aldehyde (Hantzsch, *B.* 17, 1515). Crystals (containing 3aq), v. sol. water. KH_3A^{iv} aq: small prisms or pyramids, sl. sol. cold water.—$Ba_3(NH_4)_2A^{iv}_2$ 6aq: minute tables. —Cu_2A^{iv} 7aq.

Di-phenyl-pyridine (γ)-carboxylic acid

$\mathrm{N}\left<\begin{matrix}\mathrm{CPh{:}CH}\\ \mathrm{CPh.CH}\end{matrix}\right>\mathrm{C.CO_2H}$.

[275°]. Formed by heating $(CH_2Bz)_2C(CO_2H)_2$ with alcoholic NH_3 at 120° (Paal a. Strasser, *B.* 20, 2761). Needles (from alcohol).—AgA′: pp., sl. sol. hot water.

Dihydride $C_{18}H_{15}NO_2$ *i.e.*

$\mathrm{NH}\left<\begin{matrix}\mathrm{CPh{:}CH}\\ \mathrm{CPh{:}CH}\end{matrix}\right>\mathrm{CH.CO_2H}$.

Crystalline flakes.—NH_4A'. [270°]. Formed from $(CH_2Bz)_2CH.CO_2H$ and alcoholic NH_3 in the cold. Needles, v. sol. water.

Hexahydride
$\mathrm{NH}<\begin{matrix}\mathrm{CHPh.CH_2}\\ \mathrm{CHPh.CH_2}\end{matrix}>\mathrm{CH.CO_2H}$. [339°]. Formed, in small quantity, when di-benzoyl-di-methyl-malonic acid is heated with alcoholic NH_3 at 120° (P. a. S.). Crystals, v. sl. sol. water. Yields a nitrosamine [159°].

Di-phenyl-pyridine tricarboxylic acid $\mathrm{N}\leqslant\begin{matrix}\mathrm{C(C_6H_4.CO_2H):C.CO_2H}\\ \mathrm{CPh.CH{=}C.CO_2H}\end{matrix}$. [250°]. Formed by oxidising phenyl-naphthoquinoline carboxylic acid with alkaline $KMnO_4$ below 50° (Doebner, *A.* 249, 120). Needles (from dilute alcohol).—Ag_3A''': white flocculent pp.

At 100° the chief product is phenylene phenyl-pyridylene ketone carboxylic acid $C_{19}H_{11}NO_3$ [226°], which on distillation with soda-lime yields $\mathrm{CO}<\begin{matrix}\mathrm{C_6H_4}\\ \mathrm{C_5H_2PhN}\end{matrix}$ [68°], which forms an oxim [84°] and B'_2CrO_3.

Reference.—OXY-PHENYL-PYRIDINE CARBOXYLIC ACID.

PHENYL PYRIDYL KETONE $C_{12}H_9NO$ *i.e.* $C_6H_5.CO.C_5H_4N$. (307°). Formed by heating its carboxylic acid (Bernthsen a. Mettegang, *B.* 20, 1209). Liquid. Yields a phenyl-hydrazide [143·5°].—$B'_2H_2PtCl_6$.

PHENYL (β)-PYRIDYL KETONE CARBOXYLIC ACID $C_6H_5.CO.C_5H_3N.CO_2H$. [147°]. Formed from quinolinic anhydride, benzene, and $AlCl_3$ (Bernthsen a. Mettegang, *B.* 20, 1209). Prisms, v. e. sol. hot water.

DI-PHENYL-PYRONE $\mathrm{CO}<\begin{matrix}\mathrm{CH{:}CPh}\\ \mathrm{CH{:}CPh}\end{matrix}>\mathrm{O}$. [139·5°]. Formed by heating its carboxylic acid (Feist, *B.* 23, 3734). Got also by heating de-hydro-benzoyl-acetic acid with HClAq at 245°. Needles resembling asbestos (from benzene). Its solution in conc. H_2SO_4 exhibits violet fluorescence. Alcoholic NH_3 converts it, on heating, into oxy-di-phenyl-pyridine.

DI-PHENYL-PYRONE CARBOXYLIC ACID $\mathrm{CO}<\begin{matrix}\mathrm{C(CO_2H){:}CPh}\\ \mathrm{CH{=}CPh}\end{matrix}>\mathrm{O}$. [201°]. Formed by warming chloro-dehydro-benzoyl-acetic acid (1 pt.) in H_2SO_4 (3 pts.) at 140° (Feist, *B.* 23, 3730). Small crystals (from benzene), v. sol. chloroform.—NH_4A'. [135°].—BaA'_2 6aq.—$Ag_2A'_2AgNO_3$: curdy pp.

Di-phenyl-pyrone dicarboxylic ether $\mathrm{CO}<\begin{matrix}\mathrm{C(CO_2Et){:}CPh}\\ \mathrm{C(CO_2Et){:}CPh}\end{matrix}>\mathrm{O}$. [140°]. Formed by allowing a mixture of cupric benzoyl-acetic ether (24 g.), $COCl_2$ (10 g.), and toluene (40 g.) to stand for six weeks (F.). Got also from acetone dicarboxylic ether, Et_2O, Na, and BzCl (Dünschmann a. Pechmann, *A.* 261, 189). Plates, v. sol. most solvents.

PHENYL-PYROTARTARIC ACID $C_6H_5.CH_2.CH(CO_2H).CH_2.CO_2H$. *Benzyl-succinic acid.* [161°]. Got by heating phenyl-propane tricarboxylic acid and by reducing phenyl-itaconic acid (Bischoff, *B.* 23, 653; Fittig a. Roeders, *A.* 256, 87; *cf.* Baeyer a. Perkin, *B.* 17, 449). White plates, sl. sol. cold water. Yields an anhydride [102°].—BaA'' ½aq.—CaA''.—Ag_2A''.

Phenyl-pyrotartaric acid $CO_2H.CHPh.CHMe.CO_2H$. Two varieties [171°] and [193°] are formed by saponifying the product of the reaction of NaOEt on a mixture of α-cyano-propionic acid and α-bromo-phenyl-acetic ether (Zelinsky a. Buchstab, *B.* 24, 1877). At 320° it forms an anhydride which on treatment with water yields a mixture of the two isomeric phenyl-methyl-succinic acids.

Reference.—OXY-AMIDO-PHENYL-PYROTARTARIC ACID.

PHENYL-PYROXIMIDINE DIHYDRIDE $\mathrm{CH_2}<\begin{matrix}\mathrm{CH_2.O}\\ \mathrm{CH_2.N}\end{matrix}\geqslant\mathrm{CPh}$. Formed from γ-bromo-propyl-benzamide by shaking with hot water (Gabriel, *B.* 24, 3214). Liquid, sl. sol. cold water.—$B'_2H_2PtCl_6$. [185°].—$B'C_6H_3N_3O_7$. [151°].

DI-PHENYL-PYRROLE $\mathrm{NH}<\begin{matrix}\mathrm{CPh{:}CH}\\ \mathrm{CPh{:}CH}\end{matrix}$. [143°]. Formed by the action of alcoholic potash on its carboxylic ether (Paal, *B.* 21, 3061). Got also by heating the dicarboxylic acid $C_4NH_3(C_6H_4.CO_2H)_2$ with lime (Baumann, *B.* 20, 1490). Plates (from HOAc or dilute alcohol). Forms a red solution in H_2SO_4. Colours pine-wood, moistened with HClAq, red.

Tri-phenyl-pyrrole $\mathrm{NPh}<\begin{matrix}\mathrm{CPh{:}CH}\\ \mathrm{CPh.CH}\end{matrix}$. [229°]. Formed by heating its carboxylic acid or its di-carboxylic acid $C_4NH_2Ph(C_6H_4.CO_2H)_2$ with lime (P.; B.). Needles, sl. sol. ether and alcohol.

Tri-phenyl-pyrrole $\mathrm{NH}<\begin{matrix}\mathrm{CPh{:}CPh}\\ \mathrm{CPh{:}CH}\end{matrix}$. [141°]. Formed by heating desyl-acetophenone with alcoholic NH_3 at 150° (Smith, *C. J.* 57, 645). Slender needles with violet fluorescence.

Tetra-phenyl-pyrrole $C_{28}H_{21}N$ *i.e.* $\mathrm{NH}<\begin{matrix}\mathrm{CPh{:}CPh}\\ \mathrm{CPh{:}CPh}\end{matrix}$. [214·5°]. Formed from both bidesyls by heating with alcoholic NH_3 at 150° (Garrett, *B.* 21, 3107; Fehrlin, *B.* 22, 553; Magnanini a. Angeli, *B.* 22, 855). Got also by distilling its phenyl-ν-amido- derivative (Klingemann, *A.* 269, 122). Needles or plates.

Acetyl derivative. [226°]. Needles.

Tetra-phenyl-pyrrole $\mathrm{NPh}<\begin{matrix}\mathrm{CPh{:}CPh}\\ \mathrm{CPh{:}CH}\end{matrix}$. [197°]. Formed by boiling desyl-acetophenone with aniline and HOAc (Smith, *C. J.* 57, 646). White silky needles, v. sl. sol. cold alcohol.

DI-PHENYL-PYRROLE CARBOXYLIC ACID $\mathrm{NH}<\begin{matrix}\mathrm{CPh{:}C.CO_2H}\\ \mathrm{CPh{:}CH}\end{matrix}$. [261°]. Formed by saponifying the ether, which is got by the action of alcoholic NH_3 or of boiling NH_4OAc and HOAc on di-β-benzoyl-propionic ether (Kapf a. Paal, *B.* 21, 1491, 3061). Orange needles, sl. sol. alcohol.

Ethyl ether EtA'. [159°]. Needles.

Amide $C_{17}H_{14}N_2O$. [217°].

Di-phenyl-pyrrole di-*o*-carboxylic acid $\mathrm{NH}<\begin{matrix}\mathrm{C(C_6H_4.CO_2H){:}CH}\\ \mathrm{C(C_6H_4.CO_2H){:}CH}\end{matrix}$. [232°]. Formed by heating $C_2H_4(CO.C_6H_4.CO_2H)_2$ with alcoholic NH_3 (Gabriel, *B.* 19, 840). Slender needles. Yields a nitrosamine $C_{18}H_{12}N_2O_5$ [c. 210°] crystallising from HOAc.

Tri-phenyl-pyrrole carboxylic acid $\mathrm{NPh}<\begin{matrix}\mathrm{CPh{:}C.CO_2H}\\ \mathrm{CPh{:}CH}\end{matrix}$. [273°]. Formed by saponifying the ether, which is got by boiling di-benzoyl-propionic ether with aniline and HOAc (Paal, *B.* 21, 3061). Needles (from HOAc).

Ethyl ether EtA'. [170°]. Needles.

Tri-phenyl-pyrrole di-carboxylic acid $\mathrm{NPh}<\begin{matrix}\mathrm{C(C_6H_4.CO_2H){:}CH}\\ \mathrm{C(C_6H_4.CO_2H){:}CH}\end{matrix}$. [295°]. Formed by rming $C_6H_4(CO.C_6H_4.CO_2H)_2$ with aniline Baumann, *B.* 20, 1487). Crystals, insol. water. g_2A'': bulky pp.

Ethyl ether Et_2A''. [122°]. Needles.

DI-α-PHENYL-β-PYRROYL-PROPIONIC ACID $C_4H_4N.CO.CH_2.CPh_2.CO_2H$. [216°]. Formed by saponification of di-phenyl-pyrryl-crotolactone $\begin{matrix}CH:C(C_4H_4N)\\CPh_2.CO\end{matrix}\!\!>O$ [184°] which is got by warming (α)-pyrryl methyl ketone with benzil and conc. KOHAq (Angeli, *B.* 23, 1356). Colourless crystals, almost insol. water.—KA'.—AgA': light-yellow pp.

PHENYL PYRRYL KETONE $C_{11}H_9NO$ *i.e.* $NC_4H_4.CO.C_6H_5$. [78°]. Formed by heating pyrrole with NaOBz and Bz_2O (Ciamician a. Dennstedt, *B.* 17, 2955). Yields $C_{11}H_8AgNO$.

PHENYL-PYRUVIC ACID *v.* PHENYL-GLYCIDIC ACID.

PHENYL-QUINAZOLINE $C_6H_4<\begin{matrix}CH:N\\N{=}CPh\end{matrix}$. [101°]. Got by distilling *o*-amido-benzyl-benzamide (Gabriel a. Jansen, *B.* 23, 2810). Yellow needles. Weak base.

Phenyl-quinazoline. *Dihydride.* $C_{14}H_{12}N_2$ *i.e.* $C_6H_4<\begin{matrix}CH_2.NPh\\N{=}CH\end{matrix}$. [95°]. Formed by reducing $[1:2]C_6H_4(NO_2).CH_2.NPh.CHO$ with zinc and HClAq (Paal a. Busch, *B.* 22, 2686; Donner, *Ph.* [3] 20, 43). Six-sided tables (from ether-ligroïn), almost insol. water and alkalis. Split up into aniline and benzonitrile by heating with zinc-dust.—B'HCl 2aq. [80°] when hydrated; [221°] when anhydrous. Concentric needles, sol. water.—$B'HSnCl_3$. [130°-134°]. White crystals.—$B'_2H_2PtCl_6$. [208°]. Yellow crystals.—$B'_2H_2SO_4$ 2aq. [79°]. Melts at 140°-143° when anhydrous.

Methylo-iodide B'MeI. [170°] and [180°].—$B'MeI_2$. [157°]. Golden plates.

Tetrahydride $C_6H_4<\begin{matrix}CH_2.NPh\\NH.CH_2\end{matrix}$. [117°]. Got by reduction. Needles. Yields a crystalline acetyl derivative and a brick-red nitrosamine.

Di-phenyl-quinazoline. *Dihydride.* $C_{20}H_{16}N_2$ *i.e.* $C_6H_4<\begin{matrix}CH_2.NPh\\N{=}CPh\end{matrix}$. [115°]. Formed by reduction of the benzoyl derivative of *o*-nitro-benzyl-aniline in HOAc with tin and HCl (Lellmann a. Stickel, *B.* 18, 1608). Small needles, v. sol. alcohol.—B'HCl: silky needles.

Reference.—OXY-PHENYL-QUINAZOLINE.

(*B.* 2)-**PHENYL-QUINOLINE** $\begin{matrix}CPh:CH.C.CH:CH\\CH:CH.C.N{=}CH\end{matrix}$ *p-Phenyl-quinoline.* [111°]. (260° at 77 mm.). S.G. ^{22} 1·1945. Prepared by heating *p*-amido-diphenyl with glycerin, nitrobenzene, and H_2SO_4 (La Coste, *B.* 15, 562; *A.* 230, 8). Trimetric plates (from ether).—$B'_2H_2PtCl_6$. Orange crystalline powder.—$B'_2H_2Cr_2O_7$. [136°].—**Tartrate** $B'C_4H_6O_6$ 3aq. [153°]. Needles.

Methylo-iodide B'MeI 2aq. [194°].

Ethylo-iodide B'EtI 2aq. [169°].

Tetrahydride $C_9H_{10}PhN$. Got by reduction. Unstable pp. Yields a nitrosamine $C_9H_9Ph(NO)N$ [112°], an acetyl derivative [100°], and a benzoyl derivative [137°].—B'HCl $1\frac{1}{2}$aq. [204°].—$B'C_6H_3N_3O_7$. [165°].

(*B.* 4)-**Phenyl-quinoline** $\begin{matrix}CH:CH\ .C.CH:CH\\CH:CPh.C.N{=}CH\end{matrix}$ *o-Phenyl-quinoline.* (273° at 80 mm.). Got in like manner, using *o*-amido-diphenyl (C.). Oil, with yellowish-green fluorescence.—$B'_2H_2PtCl_6$.—$B'_2H_2Cr_2O_7$. [126°]. Orange plates.

Methylo-iodide B'MeI. [163°]. Crystals, v. sol. water.—$B'_2Me_2PtCl_6$ [193°].

(*Py.* 1)-**Phenyl-quinoline** $C_6H_4<\begin{matrix}CPh:CH\\N{=}CH\end{matrix}$. [62°]. Got by heating its carboxylic acid (Königs a. Nef, *B.* 19, 2430). Needles (from ether or ligroïn). Solutions of its sulphate and hydrochloride fluoresce blue.—$B'H_2CrO_4$: needles.—$B'_2H_2PtCl_6$: yellow four-sided tables.

(*Py.* 2)-**Phenyl-quinoline** $C_6H_4<\begin{matrix}CH:CPh\\N{=}CH\end{matrix}$. Formed by adding a little NaOH to a solution of *o*-amido-benzoic aldehyde and phenyl-acetic aldehyde in dilute alcohol (Friedländer a. Gohring, *B.* 16, 1836). Oil, sparingly volatile with steam.—B'HCl. [93°].—$B'_2H_2PtCl_6$.

(*Py.* 3)-**Phenyl-quinoline** $C_6H_4<\begin{matrix}CH:CH\\NCPh\end{matrix}$. [86°]. (above 360°).

Formation.—1. By heating cinnamic aldehyde (30 pts.) with aniline (20 pts.) and conc. HClAq (20 pts.) for two hours at 210° (Grimaux, *C. R.* 96, 584; Doebner a. Miller, *B.* 16, 1665; 19, 1194).—2. By warming *o*-amido-benzoic aldehyde with acetophenone, dilute alcohol, and a little NaOH (Friedländer a. Gohring, *B.* 16, 1835).—3. By distilling *m*-oxy-phenyl-quinoline or di-oxy-phenyl-quinoline with zinc-dust (Miller a. Kinkelin, *B.* 18, 1908; Weidel, *M.* 9, 157).—4. By distilling its carboxylic acid with soda-lime (Doebner, *B.* 20, 280; *A.* 242, 294; Pfitzinger, *J. pr.* [2] 38, 583).

Properties.—Silky needles (from dilute alcohol), sol. ether, sl. sol. water. Yields $NHBz.C_6H_4.CO_2H$ [1:2] [182°] on oxidation by $KMnO_4$ in acid solution.

Salts.—$B'_2H_2PtCl_6$ 2aq.—$B'HAuCl_4$. [160°].—$(B'HCl)_2AuCl_3$. [204°]. Needles.—$B'H_2Cr_2O_7$: stable golden plates.—$B'C_6H_3N_3O_7$. [188°].

Alkylo-iodides B'MeI. [197°].—B'EtI. [195°].—$B'_2Et_2PtCl_6$.—B'EtCl 2aq.—$B'_2Et_2PtCl_6$.

Tetrahydride $C_{15}H_{15}N$. (342°). Got by reducing the base with tin and HClAq (Doebner, *B.* 19, 1198). Oil, yielding an oily nitrosamine.—B'HCl. Needles (from alcohol), v. sl. sol. water.

(*Py.* 1,3)-**Di-phenyl-quinoline** $C_6H_4<\begin{matrix}CPh:CH\\N-CPh\end{matrix}$. [112°]. Formed by heating the anilide of CH_2Bz_2 with H_2SO_4 (Beyer, *B.* 20, 1772). Mass of white crystals.—$B'_2H_2PtCl_6$ 2aq.—$B'H_2SO_4$. Needles, v. sl. sol. dilute H_2SO_4.

(*Py.* 2,3)-**Di-phenyl-quinoline** $C_6H_4<\begin{matrix}CH:CPh\\N-CPh\end{matrix}$. [96°]. (c. 420°). Formed by reducing [1:2] $C_6H_4(NO_2).CH_2.CHPh.CO.C_6H_5$ with iron and HOAc (Buddeberg, *B.* 23, 2075). Large crystals, sol. alcohol.—$B'_2H_2PtCl_6$.

(*Py.* 2)-**PHENYL-ISOQUINOLINE** $C_{15}H_{11}N$ *i.e.* $C_6H_4<\begin{matrix}CH:CPh\\CH:N\end{matrix}$. [105°]. Obtained by reduction of the (*Py.* 4)-chloro- derivative by heating it with HI and P at 170° for three hours; also by distilling phthalimide with zinc-dust (Gabriel, *B.* 18, 3477). Rhombic plates. Slightly volatile with steam.—$B'_2H_2Cl_2PtCl_4$: needles.

Tetrahydride $C_6H_4<\begin{array}{l}CH_2.CHPh.\\CH_2.NH\end{array}$ [45°-48°]. Formed by reduction of an alcoholic solution of the (*Py.*)-mono- or di- chloro-derivatives by boiling with (3 p.c.) sodium-amalgam (Gabriel, *B.* 18, 3479). Crystals, v. sol. alcohol.

References. — AMIDO-, CHLORO-, CHLORO-NITRO-, NITRO-, OXY-AMIDO-, and OXY- PHENYL-QUINOLINE.

(*Py.* 1) - **PHENYL - QUINOLINE** (*Py.* 3)-**CARBOXYLIC ACID** $C_{16}H_{11}NO_2$ *i.e.* $C_6H_4<\begin{array}{l}CPh:CH\\N{=}C.CO_2H\end{array}$. [171°]. Got by oxidation of phenyl-methyl-quinoline-phthalone with chromic acid mixture (Kœnigs a. Nef, *B.* 19, 2428). Yellow needles (from dilute alcohol), sol. acids and alkalis.

(*Py.* 3)-**Phenyl-quinoline** (*Py.* 1)-**carboxylic acid** $C_6H_4<\begin{array}{l}C(CO_2H):CH\\N{=\!=\!=\!=}CPh\end{array}$. [207°]. Formed by warming pyruvic acid with benzoic aldehyde, aniline, and alcohol (Doebner, *B.* 20, 280; *A.* 242, 291). Formed also by heating isatin with acetophenone and alcoholic potash (Pfitzinger, *J. pr.* [2] 83, 538). Needles, m. sol. cold alcohol. Yields phenyl-quinoline [84°] on distillation with soda-lime. — $(HA')_2H_2PtCl_6$. — PbA'_2aq. — CuA'_2aq. — ZnA'_2aq. — AgA': white pp.

Phenyl - quinoline - *o* - di - carboxylic acid $C_9H_4(C_6H_5)N(CO_2H)_2$ *i.e.* $C_6H_4<\begin{array}{l}CPh:C.CO_2H\\N=C.CO_2H\end{array}$. Formed by oxidation of phenyl-acridine with $KMnO_4$.

Salts.—$BaA''4aq$: glistening needles (Claus a. Nicolaysen, *B.* 18, 2706).

(*Py.* 2,3) - **Di - phenyl - quinoline carboxylic acid** $C_6H_4<\begin{array}{l}C(CO_2H):CPh\\N{=\!=\!=\!=}CPh\end{array}$. [191°]. Formed by the action of isatin and alcoholic potash on deoxybenzoïn (Pfitzinger, *J. pr.* [2] 38, 583). Needles, insol. water, v. sol. hot alcohol.

(*Py.* 3)-**PHENYL-QUINOLINE** (*B.* 2)-**SULPHONIC ACID** $\begin{array}{l}SO_3H.C:CH.C.CH:CH\\\quad\quad HC:CH.C.N{=}CPh\end{array}$. Got, together with the more soluble (*B.* 3)-sulphonic acid, by heating (*Py.* 3)-phenyl-quinoline with H_2SO_4 and SO_3 at 100° (Murmann, *M.* 13, 60).—Plates, sl. sol. water, almost insol. alcohol. Gives oxy-phenyl-quinoline [238°] when fused with potash at 250°.—BaA'_2: plates. —NH_4A': plates. —AgA': granules.

(*Py.* 3) - **Phenyl - quinoline** (*B.* 3) - **sulphonic acid.** Formed as above (M.). Granules. Yields oxy-phenyl-quinoline [156°] on fusion with potash. — $KA'aq$. — $BaA'_2 1\frac{1}{2}aq$: needles. — $AgA' 1\frac{1}{2}aq$: needles.

(*B.* 2) - **Phenyl - quinoline** *p* - **sulphonic acid** $C_{15}H_{11}NSO_3$ *i.e.* $\begin{array}{l}[1:4]SO_3H.C_6H_4.C:CH.C.CH:CH\\\quad\quad\quad\quad\quad\quad\quad HC:CH.C.N{=}CH\end{array}$. Formed, together with the following more soluble isomeride, by sulphonation of *p*-phenyl-quinoline (La Coste a. Sorger, *A.* 230, 30). Needles (containing 2aq). Turns brown, without fusion, at 300°. Alkaline $KMnO_4$ gives quinolinic acid and *p*-sulpho-benzoic acid.—NH_4A'. [above 310°].—$NaA'aq$.—HgA'_2: white pp.

(*B.* 2) - **Phenyl - quinoline** (*β*) - **sulphonic acid.** Formed as above. Plates (containing aq), not melted at 300°.—NH_4A': small scales.

PHENYL-DIQUINOLYL-METHANE. *Octohydride* $CHPh(C_9H_{10}N)_2$. [153°]. Formed from quinoline tetrahydride, benzoic aldehyde, and $ZnCl_2$ in alcohol (Einhorn, *B.* 19, 1243). Its solution in HClAq is coloured green by $FeCl_3$.

Di-phenyl-(*B.* 1)-**quinolyl-methane** $\begin{array}{l}CHPh_2.C:CH.C.CH:CH\\\quad\quad HC:CH.C.N{=}CH\end{array}$. [104°]. Formed by Skraup's method from amido-tri-phenyl-methane (Fischer a. Fränkel, *B.* 19, 749; *A.* 241, 364). Prisms, v. sol. alcohol. Yields a nitro- derivative [213°].—$B'_2H_2PtCl_6$ (dried at 100°).

DI-PHENYL-(*Py.* 3)-**QUINOLYL-UREA** $C_9H_6N.NPh.CO.NHPh$. [150°]. Formed by heating carbostyril with phenyl isocyanate and benzene at 220° (Goldschmidt a. Meissler, *B.* 23, 276). Needles (from benzene), sol. HClAq and re-ppd. by NH_3.

DI-PHENYL-QUINONE $C_{18}H_{12}O_2$ *i.e.* $CPh\Big<\begin{array}{l}CH.CO\\CO.CH\end{array}\Big>CPh$. [214°]. Formed by heating phenyl methyl diketone with NaOHAq and a little K_3FeCy_6 at 100° (Müller a. Pechmann, *B.* 22, 2130). Orange-yellow plates, m. sol. benzene. Zinc-dust and HOAc reduce it to di-phenyl-hydroquinone [219°].

DI-PHENYL-QUINOXALINE $C_6H_4<\begin{array}{l}N:CPh\\N:CPh\end{array}$. [126°]. Formed by heating benzoïn with *o*-phenylene-diamine in the air at 165° (Fischer, *B.* 24, 720). Needles.

Dihydride $C_6H_4<\begin{array}{l}NH.CHPh\\N{=}CPh\end{array}$. [149°]. Formed by heating benzoïn with *o*-phenylene-diamine at 165° with exclusion of air. Prisms. Its solutions in ether and benzene fluoresce yellowish-green.

Phenylo-hydroxide $C_6H_4<\begin{array}{l}NPh(OH):CPh\\N{=\!=\!=\!=}CPh\end{array}$. [135°]. Formed from benzil and *o*-phenylene-phenyl-diamine (Kehrmann a. Messinger, *B.* 24, 1239). — $C_{26}H_{19}N_2ClFeCl_3$. Golden prisms, m. sol. cold water, insol. ether. — $(C_{26}H_{19}N_2Cl)_2PtCl_4$. — $C_{26}H_{19}N_2HgCl_3$. Yellow scales.

Tri-phenyl-quinoxaline. *Dihydride* $C_6H_4<\begin{array}{l}NPh.CHPh\\N{=\!=}CPh\end{array}$. [117°]. Got by heating benzoïn with *o*-phenylene-phenyl-diamine in a sealed tube at 175° (Kehrmann a. Messinger, *B.* 24, 1875). Crystalline, v. sol. ether. Its solutions fluoresce bluish-green.

Tetra-phenyl-diquinoxaline, so-called. $\begin{array}{l}CPh:N.C.CH:C.N:CPh\\CPh:N.C.CH:C.N:CPh\end{array}$. [289°]. Formed from tetra-amido-benzene and benzil (Nietzki a. Müller, *B.* 22, 446). V. sol. hot HOAc. Forms a blue solution in conc. H_2SO_4.

DI-PHENYL-QUINOXALINE CARBOXYLIC ACID $C_{21}H_{14}N_2O_2$, *i.e.* $\left[4\begin{smallmatrix}2\\1\end{smallmatrix}\right]C_6H_3(CO_2H)<\begin{array}{l}N:CPh\\N:CPh\end{array}$. [288°]. Formed by mixing benzil and di-amido-benzoic acid, both dissolved in hot HOAc (Zehra, *B.* 23, 3627). Yellow plates or needles. — $BaA'_2 3aq$: needles, sl. sol. hot water.

Ethyl ether EtA'. [151°]. Needles.

TETRA-PHENYL-DIQUINOXALYL $C_{40}H_{26}N_4$, *i.e.* $\begin{array}{l}CPh:N\\CPh:N\end{array}\Big>C_6H_3.C_6H_3\Big<\begin{array}{l}N:CPh\\N:CPh\end{array}$. [above 270°]. Formed by mixing acetic acid solutions of benzil and tetra-amido-diphenyl $\{C_6H_3(NH_2)_2[1:3:4]\}_2$ (Brunner a. Witt, *B.* 20, 1026). Crystals (from phenol-HOAc). Forms a bright-red solution in conc. H_2SO_4.

PHENYL SELENIDE *v. Organic compounds* of SELENIUM.

TETRA-PHENYL-SILICANE *v. Organic compounds* of SILICON.

PHENYL SILICATE $Si(OPh)_4$. [48°]. (420°). Prepared by heating phenol with $SiCl_4$; the yield being 78 p.c. of the theoretical amount (Hertkorn, *B.* 18, 1679). Long colourless prisms, v. sol. alcohol. Decomposed by hot water into phenol and silicic acid. Boiling alcohol forms ethyl silicates and phenol.

TRI-PHENYL-STIBINE *v.* vol. i. p. 294.

PHENYL-STYRYL-HYDRAZINE $C_{15}H_{16}N_2$ *i.e.* $CHPh{:}CH.CH_2.NPh.NH_2$. [54°]. Formed from styryl bromide and sodium phenyl-hydrazide (Michaelis a. Claessen, *B.* 22, 2239). Crystals, v. sol. alcohol and ether.

PHENYL-STYRYL KETONE *v.* BENZYLIDENE-ACETOPHENONE. Its carboxylic ether is described as *Benzylidene-benzoyl-acetic ether*, vol. i. p. 481.

PHENYL-SUCCINIC ACID $C_{10}H_{10}O_4$, *i.e.* $CO_2H.CHPh.CH_2.CO_2H$. [167°].

Formation.—1. By saponification of the nitrile which is got from ω-chloro-styrene and KCy (Rügheimer, *B.* 14, 428).—2. By saponification of the product of the action of α-bromo-phenyl-acetic ether on sodium acetoacetic ether (R.).—3. At 191° from $CO_2H.CHPh.CH(CO_2H)_2$, got from α-chloro-phenyl-acetic ether and sodium malonic ether (Spiegel, *B.* 14, 873, 1693; *A.* 219, 32; Alexander, *A.* 258, 74).—4. From hydrocornicularic acid by potash-fusion (S.).

Properties.—Needles, sol. hot water and alcohol, sl. sol. chloroform. Br and PBr_3 yield a bromo- derivative [119°] converted by hot water into phenyl-maleïc acid.

Salts.—CaA''.—Ag_2A''.

Anhydride $C_{10}H_8O_3$. [c. 54°].

(α)-Di-phenyl-succinic acid $C_{16}H_{14}O_4$ *i.e.* $CO_2H.CHPh.CHPh.CO_2H$. [222°] (when dry); [183°] (when hydrated). H.C. 1,848,300 (Ossipoff, *C. R.* 109, 223). S. (alcohol) 41 at 21°.

Formation.—1. By heating α-bromo-phenyl-acetic acid with KCy (Franchimont, *B.* 5, 1018). 2. Together with the isomeric (β)-acid, by reduction of di-phenyl-maleïc anhydride with sodium-amalgam or Zn and HCl. Separated through the sparing solubility of the Ba salt (Reimer, *B.* 14, 1802; Anschütz, *A.* 259, 67).—3. By heating the (β)-isomeride with baryta-water at 200° (R.).

Properties.—Prisms (containing aq) or needles (from dilute HOAc). Yields di-phenyl-ethane and di-phenyl-ethylene when distilled with lime. HClAq at 200° converts it into the (β)-acid.

Salts.—BaA'' 2aq. S. 32 at 18°.—BaA'' 4aq.—Ag_2A'': white pp.

Mono-ethyl ether HEtA''. [140°].

Di-ethyl ether Et_2A''. [84°]. Needles.

Anhydride $C_{16}H_{12}O_3$. [116°]. (240° at 11 mm.). Formed when either of the two *s*-di-phenyl-succinic acids is heated. Got also by heating the (α)- acid with AcCl at 120° (Tillmanns, *A.* 258, 87). Trimetric crystals; *a*:*b*:*c* = ·508:1:·546. V. sol. chloroform. Yields the (α)- acid on boiling with water, and a mixture of (α)- acid (86 p.c.) and (β)- acid (14 p.c.) when treated with KOHAq.

Nitrile CN.CHPh.CHPh.CN. [160°]. Formed, together with the (β)- isomeride by heating phenyl-acetonitrile with mandelic nitrile and alcoholic KCy at 55° (Chalanay a. Knoevenagel, *B.* 25, 289). V. e. sol. alcohol. Converted into the (β)- isomeride by boiling with HOAc.

Phenylimide $C_{22}H_{17}NO_2$. [231°]. Got by heating either the (α)- or the (β)- anhydride with aniline.

Phenyl-amic acid $C_{22}H_{19}NO_3$ *i.e.* $CO_2H.CHPh.CHPh.CO.NHPh$. [220°]. Got by boiling the phenylimide with baryta (Anschütz a. Bendix, *A.* 259, 92).

(β)-Di-phenyl-succinic acid $CO_2H.CHPh.CHPh.CO_2H$. [230°]. H.C. 1,822,900. S. (alcohol) 1·24 at 21°.

Formation.—1. By heating its nitrile with HClAq at 200°.—2. By reduction of di-phenyl-maleïc anhydride. 3. By heating the α-isomeride with HClAq at 200°.

Properties.—Needles, sol. alcohol, sl. sol. benzene, insol. water. On distillation *in vacuo* at 250° it yields a mixture of the (α)- anhydride (89 p.c.) and the (β)- anhydride (11 p.c.).

Reactions.—1. Yields *s*-di-phenyl-ethane and di-phenyl-ethylene on distillation with lime (Reimer, *B.* 14, 1802).—2. Baryta-water at 200° converts it into the (α)- isomeride.

Salts.—BaA'' 7aq. S. 21 at c. 18°.—Ag_2A''.

Ethyl ether Et_2A''. [141°]. Needles.

Anhydride $\begin{matrix}CHPh.CO\\CHPh.CO\end{matrix}\!\!>\!O$. [c. 107°]. Formed by heating the (β)- acid with AcCl at 100°, and also by the action of AcCl on its salts. When boiled with water it yields the (α)- acid (75 p.c.) and some (β)- acid (25 p.c.). Cold KOHAq forms only the (β)- acid. On heating with aniline it gives the phenylimide [231°].

Diphensuccindone

$C_6H_4\!<\!\begin{matrix}CO.CH—\\—CH.CO\end{matrix}\!>\!C_6H_4$? [202°].

Formed by heating the acid (5 g.) with conc. H_2SO_4 (8 g.) until dissolved, and then pouring into water (Roser, *A.* 247, 153). White crystals, insol. water, sol. alcohol. Yields a dioxim $C_{16}H_{10}(NOH)_2$ [254°] and a phenyl-hydrazide $C_{16}H_{10}(N_2HPh)_2$ [c. 265°]. Reduced by HI and P to $C_{16}H_{14}$ [100°].

Nitrile CN.CHPh.CHPh.CN. [240°]. Accompanies the (α)- isomeride (*v. supra*). Colourless needles, sol. hot alcohol.

Tetra-phenyl-succinic acid $CO_2H.CPh_2.CPh_2.CO_2H$. [262°]. Formed by heating α-chloro-di-phenyl-acetic ether with finely-divided silver at 125° (Bickel, *B.* 22, 1538). Insol. water, v. sol. alcohol and ether.

Ethyl ether Et_2A''. [89°].

Nitrile $CN.CPh_2.CPh_2.CN$. [c. 230°]. Formed by the action of NaOEt and I on di-phenyl-acetonitrile (Auwers a. V. Meyer, *B.* 22, 1227; *cf.* Anschütz a. Romig, *A.* 233, 349). Formed also by the action of nitrous acid on di-phenyl-acetonitrile (Neure, *A.* 250, 148). Flat needles (from HOAc), v. sl. sol. hot alcohol. Liquefied by heating for a long time at 180°.

Phenyl-isosuccinic acid *v.* BENZYL-MALONIC ACID.

References.—NITRO- and OXY- PHENYL-SUCCINIC ACIDS.

DI-PHENYL-SUCCINIMIDINE $C_{16}H_{15}N_3$ *i.e.* $C_2H_4\!<\!\begin{matrix}C(NH)\\C(NPh)\end{matrix}\!>\!NPh$. Formed from ethylene

cyanide and aniline hydrochloride at 154° (Blochmann, *B.* 20, 1856). Greyish-yellow crystals, insol. water. Yields the phenylimide of succinic acid when boiled with HClAq.—B'HCl.—$B'_2H_2PtCl_6$.—$B'H_2SO_4$.—B'HBr.—B'HI.

PHENYL-SULPHAMIC ACID $C_6H_7NSO_3$ *i.e.* $C_6H_5NH.SO_3H$. Formed as a salt from $ClSO_3H$ (1 mol.), aniline (3 mols.) and chloroform in the cold. Got also by the action of solid fuming sulphuric acid on aniline in $CHCl_3$ at a low temperature (Wagner, *B.* 19, 1157; Traube, *B.* 23, 1655; 24, 360).—NaA'.—KA': leaflets, sol. hot alcohol.—$BaA'_2$2aq: leaflets or needles, sol. hot water. Decomposed by acids into aniline and H_2SO_4.—NH_2PhHA'. [192°]. Plates.

PHENYL SULPHATE.

Hydrogen phenyl sulphate $C_6H_5O.SO_2.OH$. *Phenyl-sulphuric acid.* Occurs in urine of horses, men, and dogs (Baumann, *B.* 9, 55; 11, 1907; *H.* 2, 335), the quantity being greatly increased by administration of phenol. The K salt is formed by adding $K_2S_2O_7$ (125 pts.) to a solution of phenol (100 pts.) and KOH (60 pts.) in water (90 pts.) at 65°. The free acid quickly splits up, in aqueous or alcoholic solution, into phenol and H_2SO_4.—KA'. S. 14 at 15°. Plates (from alcohol). Not attacked by potash. The dry salt changes at 150°-160° into phenol *p*-sulphonic acid.—$BaA'_2$3aq: needles.

DI-PHENYL SULPHAZIDE *v. Phenyl-hydrazide* of BENZENE SULPHONIC ACID.

DI-PHENYL SULPHIDE $C_{12}H_{10}S$ *i.e.* Ph_2S. Mol. w. 186. (293°). S.G. 1·119.

Formation.—1. By the dry distillation of sodium benzene sulphonate (Stenhouse, *Pr.* 14, 351; *A.* 140, 288).—2. From $S(C_6H_4.NH_2)_2$ by elimination of NH_2 by the diazo-reaction (Krafft, *B.* 7, 384, 1164).—3. By distilling $Pb(SPh)_2$ (Kekulé a. Szuch, *C. R.* 64, 752).—4. By the action of Na on $SO(C_6H_5)_2$ (Colby a. McLoughlin, *Am.* 9, 67).—5. By the action of NaSPh on $C_6H_5.N_2Cl$ in molecular proportions (Ziegler, *B.* 23, 2471).—6. By heating benzene with S and $AlCl_3$ at 80° (Friedel a. Crafts, *A. Ch.* [6] 14, 438).

Preparation.—Ammonium sulphide is slowly added to an acid solution of diazobenzene, cooled with ice, the oil which separates is cohobated for 2 or 3 hours to decompose the disulphide, and finally distilled; the yield is good (Graebe a. Mann, *B.* 15, 1683).

Properties.—Oil, with slightly alliaceous odour, v. sol. hot alcohol, miscible with ether. Its alcoholic solution is not ppd. by $AgNO_3$ or $HgCl_2$. Yields di-phenyl-sulphone on oxidation.

Di-phenyl disulphide Ph_2S_2. Mol. w. 218. [61°]. (310°).

Formation.—1. By oxidising phenyl mercaptan with dilute HNO_3 (Vogt, *A.* 119, 142; Otto, *A.* 143, 213), with chromic acid mixture (Kekulé, *Z.* 1867, 194), and by exposure of its ammoniacal solution to air.—2. From NaSPh and CyCl (Clemm, *J. pr.* [2] 1, 147).—3. Together with mercury by distilling $Hg(SPh)_2$ (Dreher a. Otto, *A.* 154, 178).—4. From NaSPh and I (Hübner a. Alsberg, *A.* 156, 330).—5. In small quantity by adding zinc-dust to a mixture of S_2Cl_2 and benzene (Schmidt, *B.* 11, 1173).—6. By reducing $C_6H_5.SO_2Cl$ with HI (Cleve, *B.* 21, 1100).—7. By heating $C_6H_5SO_2H$ with HSPh (Otto, *B.* 9, 1589).—8. By passing SO_2 into a solution of phenyl-hydrazine in benzene, and heating to boiling (Michaelis a. Ruhl, *B.* 23, 476).

Properties.—Needles, with faint odour, insol. water, v. sol. alcohol and ether.

Reactions.—1. Reduced by zinc and dilute H_2SO_4 to C_6H_5SH.—2. Oxidised by nitric acid to benzene sulphonic acid.—3. Split up by long boiling into Ph_2S and S (Graebe, *A.* 174, 189).—4. Alcoholic potash forms KSPh and $C_6H_5SO_2K$. 5. Alcoholic K_2S forms KSPh.—6. Bromine forms crystalline Ph_2SBr_2.

Di-phenyl tetra-sulphide $(C_6H_5)_2S_4$. S.G. $\frac{14·5}{}$ 1·297. Formed by the action of H_2S on a conc. alcoholic solution of benzene sulphinic acid (Otto, *J. pr.* [2] 37, 208). Formed also by the action of S_2Cl_2 on phenyl mercaptan. Thick yellow oil, m. sol. alcohol, v. sol. ether.

Di-phenyl hexasulphide $(C_6H_5)_2S_6$. An amorphous solid formed by heating benzene (20 g.) with S_2Cl_2 (10 g.) and iodine (1 g.) for 100 hours at 120° (Onufrovitch, *B.* 23, 3368).

References.—AMIDO-, AMIDO-IMIDO-, BROMO-, CHLORO-, CHLORO-NITRO-, IODO-, NITRO-, and OXY-DI-PHENYL SULPHIDES. *V.* also DI-PHENYL-DI-PHENYL SULPHIDE.

DI-PHENYL SULPHIDE *o*-CARBOXYLIC ACID $C_6H_5.S.C_6H_4.CO_2H$. Formed by the action of alkalis on the product of the action of NaSPh on diazotised *o*-amido-benzoic acid (Ziegler, *B.* 23, 2471). Plates (from benzene), insol. water.

PHENYL SULPHINIC ACID is BENZENE SULPHINIC ACID.

Diphenyl sulphinic acid $C_6H_4Ph.SO_2H$. Got by reducing $C_{12}H_9.SO_2Cl$ in ether with sodium-amalgam (Gabriel a. Deutsch, *B.* 13, 388). Crystalline powder, decomposing at about 70°.

PHENYL SULPHITE (Schall, *B.* 25, 1490, 1875). The salt $NaSO_2.OPh$ is formed from NaOPh and SO_2, and exhibits the following reactions:—1. *Alkyl iodides* convert it into phenyl ethers of the sulphonic acids $R.SO_2.OH$.—2. *Benzyl ether* forms phenyl benzyl oxide, SO_2, and NaCl at 180° (yield 16 p.c.).—3. $COCl_2$ forms $CO(OPh)_2$, SO_2, and NaCl at 180°.—4. *Iodoform* (1 mol.) heated with $NaSO_2.OPh$ (3 mols.) at 180° forms MeI, $CH_3.SO_2.OPh$, and 'rubbadin.'

Rubbadin $C_{44}H_{32}S_4O_8$, mol. w. 830 (by Raoult's method, calc. 806). Rub. crystallises from dilute alcohol in minute brownish-red plates, S. (alcohol) 43 at 20°, and forms a claret-coloured solution in alkalis. Its solution in NH_3Aq dyes silk and wool pale-claret colour, and cotton yellowish-violet.

Reactions.—1. Reduced by zinc-dust and NaOHAq to $C_{44}H_{34}S_4O_8$.—2. Conc. HNO_3, free from nitrous fumes, at 0° forms $C_{44}H_{26}(NO_2)_6S_4O_8$, a red crystalline powder, m. sol. hot alcohol, which may be reduced to $C_{44}H_{26}(NO_2)_4(NH_2)_2S_4O_8$, a glittering black crystalline powder (from ether-phenol) which yields a black crystalline di-acetyl derivative.—3. HClAq at 200° forms phenol (2 mols.), H_2S (2 mols.), and $C_{32}H_{20}S_2O_8$, a reddish-brown crystalline powder which yields the derivatives $C_{32}H_{18}Ac_2S_2O_8$, $C_{32}H_{18}Me_2S_2O_8$, and $C_{32}H_{14}Br_4Ac_2S_2O_8$.—4. Fusion with NaOH forms $SO(C_6H_4.OH)_2$ [96°] and salicylic acid.

Di-acetyl derivative $C_{44}H_{30}Ac_2S_4O_8$. Dark-brown powder, decomposed by heat without previous fusion. Split up by long boiling with alcohol into $C_{32}H_{21}S_2O_8$, sol. alcohol and $C_{24}H_{22}S_2O_4$, insol. alcohol. Br in chloroform converts the di-acetyl derivative into $C_{44}H_{24}Br_6Ac_2S_4O_8$.

Di-methyl-rubbadin $C_{44}H_{30}Me_2S_4O_8$. Got from rubbadin, KOHAq, and MeI. Dark reddish-brown powder.

PHENYL SULPHOCYANIDE $C_6H_5.SCN$. (231° cor.). S.G. $\frac{17.5}{}$ 1·155. Formed from $Pb(SPh)_2$ and CyCl. Prepared by adding cuprous sulphocyanide to a solution of diazobenzene sulphate and potassium sulphocyanide (Billeter, *B.* 7, 1753; Gattermann a. Haussknecht, *B.* 23, 738). Liquid. Yields phenyl mercaptan when heated with alcoholic potash.

Polymeride $(Ph.SCy)_3$. [97°]. Got from PhSNa and cyanuric chloride (Klason, *J. pr.* [2] 33, 120). Prisms (from HOAc).

Reference.—NITRO-PHENYL SULPHOCYANIDE.

PHENYL SULPHOCYANO-ETHYL KETONE $C_{10}H_9NSO$ *i.e.* $C_6H_5.CO.C_2H_4.SCy$. Got from $C_6H_5.CO.C_2H_4Br$ and KSCy in alcohol (Pampel a. Schmidt, *B.* 19, 2897). Liquid.

DI-PHENYL SULPHONE $(C_6H_5)_2SO_2$. *Sulphobenzide.* Mol. w. 218. [128°]. (376°) at 722 mm.

Formation. — 1. From benzene and SO_3 (Mitscherlich, *P.* 31, 628; Freund, *A.* 120, 76; Otto, *A.* 136, 160), fuming H_2SO_4 (Berthelot, *B.* 9, 349), or HSO_3Cl (Knapp, *Z.* [2] 5, 41). - 2. By oxidation of Ph_2S (Stenhouse, *A.* 140, 290; Kekulé a. Szuch, *Bl.* [2] 8, 204).—3. By distilling benzene sulphonic acid (F.). - 4. From benzene, $C_6H_5SO_2Cl$, and $AlCl_3$; the yield being 80 p.c. of the theoretical amount (Beckurts a. Otto, *B.* 11, 2066).—5. By heating benzene (200 c.c.) with conc. H_2SO_4 (300 c.c.), the yield being 6 p.c. of the benzene employed (Istrati, *Bl.* [3] 1, 492).—6. By heating $C_6H_5.SO_2Cl$ with $HgPh_2$ (Otto, *B.* 18, 248).—7. By oxidation of di-phenyl sulphoxide with $KMnO_4$ and HOAc (Colby a. McLoughlin, *Am.* 9, 67).

Properties.—Monoclinic prisms (from benzene) or plates (from alcohol), v. sol. ether. PCl_5 at 160° forms $C_6H_5SO_2Cl$ and chloro-benzene. Converted by potash-fusion into phenol, diphenyl, Ph_2S, PhSH, and other bodies (Otto, *B.* 19, 2425). Hot fuming H_2SO_4 forms benzene sulphonic acid.

References. — AMIDO-, BROMO-, CHLORO-, NITRO-, OXY-AMIDO-, and OXY- DI-PHENYL SULPHONES.

PHENYL SULPHONE ACETIC ACID *v.* PHENYL-SULPHONO-ACETIC ACID.

DI-PHENYL SULPHONE *o*-**CARBOXYLIC ACID** $C_{13}H_{10}SO_4$ *i.e.* $C_6H_5.SO_2.C_6H_4.CO_2H$. [152°]. Formed by oxidising $PhS.C_6H_4.CO_2H$ with HNO_3 (Graebe a. Schultess, *A.* 263, 7). Needles (containing aq). Melts at 99° when hydrated.

Di-phenyl sulphone *p*-**carboxylic acid.** [above 300°]. Got by oxidation of phenyl tolyl sulphone with $KMnO_4$ (Michael a. Adair, *B.* 11, 119). Prisms (from alcohol), sl. sol. hot water.—AgA′.

Di-phenyl sulphone di-carboxylic acid $SO_2(C_6H_4.CO_2H)_2$. [above 300°]. Got by oxidising di-*p*-tolyl sulphone (M. a. A.). Small prisms, sol. nitrobenzene.

DI-PHENYL SULPHONE *m*-**SULPHONIC ACID** $C_6H_5.SO_2.C_6H_4.SO_3H$. Got by heating di-phenyl sulphone (1 mol.) with $HO.SO_2Cl$ (1 mol.) at 150° (Otto, *B.* 11, 2075; 19, 2417). Fibrous crystalline mass, v. sol. water. — KA′aq.—NaA′3aq.—$CaA'_2$7aq.—$BaA'_2$4½aq.—$PbA'_2$3½aq.—$CuA'_2$7½aq.

Chloride. [99°]. White needles.

Amide $Ph.SO_2.C_6H_4.SO_2NH_2$. [154°].

Anilide. [131°]. Hard nodules.

Ethers.—EtA′. [89°].—PhA′. [106°].

Di-phenyl sulphone di-sulphonic acid $SO_2(C_6H_4.SO_3H)_2$. Formed from di-phenyl sulphone (1 mol.) and $HO.SO_2Cl$ (2 mols.) at 155° (Otto, *B.* 19, 3124). Deliquescent mass.—K_2A''aq.—Na_2A''3aq.—CaA″6½aq.—BaA″5aq.—PbA″3aq.—CuA″3½aq.

Chloride $C_{12}H_8S_3O_6Cl_2$. [176°]. Plates.

Amide. [242°]. Nearly insol. ether.

Anilide. [212°]. Lustrous plates.

Ethers Et_2A''. [82°].—Ph_2A''. [193°].

DIPHENYL SULPHONIC ACID $C_{12}H_{10}SO_3$ *i.e.* $C_6H_4Ph.SO_3H$. Formed, together with the di-sulphonic acid, by heating diphenyl with H_2SO_4 (Engelhardt a. Latschinoff, *B.* 4, 561; 6, 193).—KA′aq. Crystals (from 40 p.c. alcohol).—BaA'_2.—$CuA'_2$6aq.

Ethyl ether EtA′. [74°]. Needles.

Chloride $C_{12}H_9.SO_2Cl$. [115°].

Amide $C_{12}H_9.SO_2NH_2$. [227°-230°]. Slender needles (Gabriel a. Deutsch, *B.* 13, 386).

Diphenyl di-*o*-sulphonic acid $C_{12}H_{10}S_2O_6$ *i.e.* $SO_3H.C_6H_4.C_6H_4.SO_3H$. Formed by elimination of NH_2 from benzidine disulphonic acid (Limpricht, *A.* 261, 327). Viscid mass. Yields di-oxy-diphenyl [99°] by potash-fusion. BaA″6½aq.—PbA″5aq: needles, v. e. sol. water.

Chloride $C_{12}H_8(SO_2Cl)_2$. [138°]. Prisms.

Amide $C_{12}H_8(SO_2NH_2)_2$2aq. Prisms.

Anilide $C_{12}H_8(SO_2NHPh)_2$. [157°].

Diphenyl di-*p*-sulphonic acid $C_{12}H_8(SO_3H)_2$. [72·5°]. Formed by sulphonating diphenyl (Fittig, *A.* 132, 209; Engehardt, *Z.* 1871, 260). Deliquescent prisms. — K_2A''2½aq.—CaA″.—BaA″.

Chloride. [203°] (G. a. D.). Prisms.

Amide. [above 300°]. Needles.

References.—NITRO-, OXY-AMIDO-, and OXY-DIPHENYL SULPHONIC ACID.

PHENYL-SULPHONO-ACETIC ACID $C_8H_8SO_4$ *i.e.* $C_6H_5.SO_2.CH_2.CO_2H$. [112°].

Formation.—1. From sodium benzene sulphinate and chloro-acetic acid (Gabriel, *B.* 14, 834).—2. By saponifying its ether, which is got by boiling sodium benzene sulphinate with chloro-aceto-acetic ether (Otto a. Rössing, *B.* 23, 755).—3. By oxidising phenyl-thio-glycollic acid (Claesson; Blomstrand, *B.* 4, 712; 8, 120; Otto, *B.* 19, 3138).—4. By warming phenyl oxy-ethyl sulphone (1 vol.) with H_2SO_4 (1 vol.), diluted with water (2 vols.), and extracting with ether (Otto, *J. pr.* [2] 30, 340).

Properties.—Monoclinic crystals, m. sol. water, but separated by addition of NaCl. Sol. alcohol and ether.

Reactions.—1. Reduced by sodium amalgam to benzene sulphinic and acetic acids.—2. Gives off CO_2 above 160°, forming phenyl methyl sulphone.—3. *Chlorine*, passed into its warm aqueous solution, forms $CHCl_2.SO_2.C_6H_5$ [59°].—4. PCl_5 gives the chloride [58°], and at 110° forms $C_6H_5.SO_2.CCl_2.COCl$, which on treatment with water gives $C_6H_5.SO_2.CHCl_2$ (Otto, *J. pr.* [2] 40, 540).

Salts.—$BaA'_2$2aq.—$CuA'_2$2aq.—$CaA'_2$2½aq.—$PbA'_2$2aq.—AgA′. Sparingly soluble needles.

Methyl ether MeA′. Oil (Otto, *J. pr.* [2] 36, 436).

Ethyl ether EtA′. [42°] (O.). Readily saponified by NaOHAq, while KOHAq gives phenyl methyl sulphone. Bromine at 90°, followed by NaOHAq, forms $C_6H_5.SO_2.CHBr_2$ [76°]. Alcoholic potash forms $Ph.SO_2.Me$ (Michael a. Milner, *Am.* 7, 65). NaOEt forms the compound $C_6H_5.SO_2.CHNa.CO_2Et$, which yields Ph_2S_2, Ph_2S, PhSEt, and $Ph.SO_2Me$ on distillation (Otto a. Rössing, *B.* 22, 1453; 23, 1647).

Chloride $Ph.SO_2.CH_2.COCl$. [58°].

Amide $Ph.SO_2.CH_2.CONH_2$. [153°]. Needles (from water). Yields $Hg(C_8H_8NSO_3)_2$ [215°] on boiling with HgO.

PHENYL-SULPHONO-ACETONE *v.* PHENYL METHYLENE METHYL SULPHONE-KETONE.

Di-phenyl-di-sulphono-acetone *v.* DI-PHENYL DI-METHYLENE DISULPHONE-KETONE.

PHENYL-SULPHONO-ANGELIC ETHER $C_{13}H_{16}SO_4$ *i.e.* $C_6H_5.SO_2.CH(C_3H_5)CO_2Et$. [64·5°]. Got from $PhSO_2.CHNa.CO_2Et$ and allyl iodide (Michael, *Am.* 7, 67). Prisms (from alcohol).

PHENYL-SULPHONO-*n*-BUTYRIC ACID $C_6H_5.SO_2.CHEt.CO_2H$. [124°]. Formed from benzene sulphinic acid, α-bromo-butyric acid, and Na_2CO_3Aq (Otto, *B.* 21, 996). Needles, m. sol. water. Yields phenyl propyl sulphone on heating.

Di-phenyl-di-sulphono-butyric ether $(C_6H_5.SO_2)_2CMe.CH_2.CO_2Et$. [97°]. Got by oxidation of $(PhS)_2CMe.CH_2.CO_2Et$ (Autenrieth, *A.* 259, 367). Small crystals, insol. water. Converted by KOHAq into benzene sulphinic acid and β-phenyl-isocrotonic acid.

PHENYL-SULPHONO-CROTONIC ACID $C_6H_5.SO_2.CMe{:}CH.CO_2H$. [158°]. S. ^{15} ·38; ^{100} 25. Formed by heating the Na salt of β-chloro-crotonic acid [94·5°] with sodium benzene sulphinate in aqueous solution at 170° (Autenrieth, *A.* 259, 343). Plates (from water), m. sol. ether. At 210° it slowly changes to the following isomeride [127°].—KA′ $1\frac{1}{2}$aq.—BaA′$_2$ aq.—MgA′$_2$ 7aq.—ZnA′$_2$ 6aq.—CuA′$_2$ aq.—AgA′. [200°]. Matted needles (from water).

Phenyl-sulphono-isocrotonic acid $C_6H_5.SO_2.CMe{:}CH.CO_2H$. [127°]. S. ·26 at 15°; 5 at 100°. Formed by heating β-chloro-isocrotonic acid with sodium benzene sulphinate in aqueous solution at 145°. Got also by saponifying di-phenyl-di-sulphono-isobutyric ether (Autenrieth, *A.* 259, 335). Feathery needles. Yields benzene sulphinic acid [81°] on boiling with potash.—KA′ 3aq.—BaA′$_2$ $2\frac{1}{2}$aq.—MgA′$_2$ 6aq.—ZnA′$_2$ 6aq. [120°] (hydrated).—AgA′. [c. 243°].

Ethyl ether EtA′. Oil.

DI-PHENYL-DI-SULPHONO-DI-ETHYL OXIDE $C_{16}H_{18}S_2O_5$ *i.e.* $O(C_2H_4.SO_2Ph)_2$. [70°]. Formed from $C_6H_5.SO_2.C_2H_4Cl$ and dry Ag_2O (Otto, *J. pr.* [2] 30, 202). Needles, sol. benzene. A polymeride [88°] is got by heating the compound $(C_6H_5.SO_2)_2C_2H_4$ with KOHAq.

DI-PHENYL-DI-SULPHONO-DI-ETHYL SULPHIDE $S(C_2H_4.SO_2Ph)_2$. [124°]. Got from $C_6H_5.SO_2.C_2H_4Cl$ and alcoholic KSH (Otto, *J. pr.* [2] 30, 348). Needles (from dilute alcohol).

DI-PHENYL-DI-SULPHONO-HEXOIC ETHER $(C_6H_5.SO_2)_2CMe.CHEt.CO_2Et$. [111°]. Got by oxidising $(PhS)_2CMe.CHEt.CO_2Et$ (Autenrieth, *A.* 259, 372). Crystals, v. sol. alcohol.

DI-PHENYL-DI-SULPHONO-DI-PHENYL OXIDE $(C_6H_5.SO_2.C_6H_4)_2O$. [70°]. (above 200°). Got by heating $C_6H_4(SO_2Ph)_2$ with alcoholic potash at 165° (Otto a. Rössing, *B.* 20, 187). Needles, v. e. sol. alcohol, insol. water.

PHENYL-α-SULPHONO-PROPIONIC ACID $C_6H_5.SO_2.CHMe.CO_2H$. [116°]. Formed by heating α-bromo-propionic ether with sodium benzene sulphinate and ether. Minute needles.—NaA′.—BaA′$_2$ 2aq.—EtA′. [c. 17°].

Phenyl-β-sulphono-propionic acid $C_6H_5.SO_2.CH_2.CH_2.CO_2H$. [124°]. Got from β-bromo-propionic acid, benzene sulphinic acid, and Na_2CO_3Aq (Otto, *B.* 21, 89). Plates, sl. sol. cold water.

DI-PHENYL SULPHOXIDE $(C_6H_5)_2SO$. [71°]. Formed by the action of SO_2 or $SOCl_2$ on benzene in presence of $AlCl_3$ (Colby a. McLoughlin, *Am.* 9, 67; *B.* 20, 195). Triclinic crystals, v. sol. alcohol. Oxidised by $KMnO_4$ to Ph_2SO_2. Reduced by sodium to Ph_2S. $NaNO_2$ and H_2SO_4 give $SO(C_6H_4.NO_2)_2$ [116°] and $SO_2(C_6H_4.NO_2)_2$ [163°].

Di-phenyl-di-sulphoxide *v. Phenyl ether* of BENZENE THIOSULPHONIC ACID.

PHENYL-SULPHURIC ACID *v.* PHENYL SULPHATE and PHENOL, *Reaction* 19.

PHENYL SULPHUROUS ACID *v.* BENZENE SULPHONIC ACID.

PHENYL SULPHYDRATE *v.* PHENYL MERCAPTAN.

PHENYL-SULPHYDRO-ACETIC ACID *v.* PHENYL-THIOGLYCOLLIC ACID.

PHENYL-SULPHYDRO-ACETOPHENONE $C_6H_5.CO.CH_2.SPh$. [53°]. Formed from ω-bromo-acetophenone and NaSPh (Delisle, *B.* 22, 306). Crystals, v. sol. ether and acetone.

DI-PHENYL-DI-SULPHYDRO-BUTYRIC ETHER $C_{18}H_{20}S_2O_2$ *i.e.* $(PhS)_2CMe.CH_2.CO_2Et$. [58°]. Got by passing HCl into a mixture of acetoacetic ether and phenyl mercaptan (Escales a. Baumann, *B.* 19, 1790). Pearly plates (from alcohol), v. sol. ether.

PHENYL-SULPHYDRO-CROTONIC ACID $CH_3.CH{:}C(SPh).CO_2H$. [86°]. Formed by the action of Na and phenyl mercaptan on the Na salt of α-chloro-crotonic acid [97°] (Autenrieth, *A.* 254, 246). Needles or plates. Its K salt is hygroscopic, S. (alcohol) 20·8.

Isomeride $CHMe{:}C(SPh).CO_2H$. [80°]. Got in like manner from the stereo-isomeric liquid chloro-crotonic acid. White plates. Its K salt is hygroscopic, S. (alcohol) 10·4.

Phenyl-β-sulphydro-crotonic acid $CH_3.C(SPh){:}CH.CO_2H$ or $CH_2{:}C(SPh).CH_2.CO_2H$. [177°]. S. (alcohol) 2 in the cold. Formed, together with small quantities of an isomeride [145°], by warming di-phenyl-di-sulphydro-butyric ether with alcoholic soda (Escales a. Baumann, *B.* 19, 1791). Plates (from alcohol), insol. water.—BaA′$_2$ 2aq.—AgA′: amorphous pp.

Isomeride $CH_3.C(SPh){:}CH.CO_2H$. [158°]. Formed from phenyl mercaptan and the Na salt of chloro-crotonic acid [95°] (Autenrieth, *A.* 254, 230). Both acids form a cherry-red solution in H_2SO_4.

DI-PHENYL SULPHYDRO-ETHYLIDENE DISULPHONE. *Phenyl derivative* $(C_6H_5.SO_2)_2CMe.SPh$. [194°]. Got by heating $(C_6H_5.SO_2)_2CH.SPh$ with alcoholic soda and

MeI at 100° (Laves, *B.* 23, 1416). Crystals (from chloroform).

DI-PHENYL-DI-SULPHYDRO-HEXOIC ETHER $CH_3.C(SPh)_2.CHEt.CO_2Et$. [71°]. Got from ethyl-acetoacetic ether, phenyl mercaptan, and HCl (Autenrieth, *A.* 259, 371). Shining crystals, v. sol. ether and alcohol.

DI-PHENYL SULPHYDRO-METHENYL DISULPHONE. *Phenyl derivative* $(C_6H_5.SO_2)_2CH.SPh$. [175°]. Got by the action of $KMnO_4$ and dilute H_2SO_4 on $CH(SPh)_3$ dissolved in benzene (Laves, *B.* 23, 1414). Silky needles, m. sol. chloroform, nearly insol. water and alcohol, sol. alcoholic NaOH. May be oxidised to $CH(SO_2Ph)_3$ [215°].

DI-PHENYL-DI-SULPHYDRO-PHENYL-ACETIC ACID $C_6H_5.C(SPh)_2.CO_2H$. [143°]. Formed from phenyl-glyoxylic acid, phenyl-mercaptan, and HCl (Escales a. Baumann, *B.* 19, 1789). Insol. water, v. sol. ether. Crystallises from benzene with $\frac{1}{2}C_6H_6$.—KA′ 1½aq.

PHENYL-SULPHYDRO-PHENYL-THIO-BIAZYL-HYDRAZINE $\begin{smallmatrix}\mathrm{NPh.N}\\ \mathrm{CS-S}\end{smallmatrix}\!>\!\mathrm{C.NH.NHPh}$.
[142°]. Got by reducing the corresponding azo-compound with alcoholic ammonium sulphide (Freund a. Kuh, *B.* 23, 2830). Plates, sl. sol. alcohol.

DI-PHENYL-DI-SULPHYDRO-PROPIONIC ACID $CH_3.C(SPh)_2.CO_2H$. [117°]. Got from pyruvic acid, phenyl mercaptan, and HCl (Escales a. Baumann, *B.* 19, 1787). Needles (from ligroïn).—NaA′.—BaA′$_2$2aq: v. sol. hot Aq.

Amide. [93°]. Needles (from alcohol).

DI-PHENYL SULPHYDRO-PROPYLENE DISULPHONE. *Phenyl derivative* $C_6H_5.SO_2.CH_2.CMe(SPh).SO_2.C_6H_5$. [119°]. Formed by oxidising $C_6H_5.SO_2.CH_2.CMe(SPh)_2$ with $KMnO_4$ in the cold (Otto a. Rössing, *B.* 24, 234). Crystalline granules, sl. sol. cold alcohol.

DI-PHENYL-DI-SULPHYDRO-VALERIC ACID $CH_3.C(SPh)_2.CH_2.CH_2.CO_2H$. [69°]. Got from phenyl mercaptan, β-acetyl-propionic acid and HCl (Escales a. Baumann, *B.* 19, 1795). Prisms (from chloroform-ether).—BaA′$_2$.

PHENYL-TETRIC ACID $C_{11}H_{10}O_3$ *i.e.* $\begin{smallmatrix}\mathrm{CH_2Ph.CH.CO}\\ \mathrm{CO.CH_2}\end{smallmatrix}\!>\!\mathrm{O}$. Formed by heating bromo-benzylacetoacetic ether (Moscheles, *B.* 21, 2608). Not affected by HClAq at 170°. Yields a benzoyl derivative $C_{11}H_9BzO_3$ [110°] crystallising in needles.

PHENYL-THIAZOLE C_9H_7NS *i.e.* $\mathrm{N}\!<\!\begin{smallmatrix}\mathrm{CH\ .S}\\ \mathrm{CPh:CH}\end{smallmatrix}$. [52°]. (273° cor.). Got by the diazo- reaction from the amido-phenyl-thiazole that is produced by the action of thio-urea on bromo-acetophenone (Popp, *A.* 250, 279; *cf.* Arapides, *A.* 249, 25). Sl. sol. cold water.—B′HCl. [80°]. Needles.—B′$_2$H$_2$PtCl$_6$ 2aq. [196°].—B′HHgCl$_3$. [153°].—**Picrate.** [165°].—B′HAuCl$_4$. [175°]. Needles (from alcohol).

μ-Phenyl-thiazole $\mathrm{N}\!<\!\begin{smallmatrix}\mathrm{CPh.S}\\ \mathrm{CH\ :CH}\end{smallmatrix}$. (269°). Formed by heating thio-benzamide with di-chloro-di-ethyl oxide at 100°. Oil.—B′HCl 2aq. [62°].—B′$_2$H$_2$PtCl$_6$2aq. [175°] (when anhydrous).—**Picrate.** [125°]. Yellow needles.

Dihydride $\mathrm{N}\!<\!\begin{smallmatrix}\mathrm{CPh.S}\\ \mathrm{CH_2.CH_2}\end{smallmatrix}$. *Phenyl-thiazoline.* (276). Got by heating thio-benzamide with ethylene bromide (Gabriel a. Heymann, *B.* 23, 158; 24, 784). Formed also by the action of PCl_5 on $S_2(C_2H_4.NHBz)_2$ (Gabriel a. Coblentz, *B.* 24, 1124). Oil. Yields a crystalline dibromide. — B′$_2$3HCl. — B′$C_6H_3N_3O_7$. [172°]. Yellow needles.—B′$_2$H$_2$PtCl$_6$.

ν-Phenyl-thiazole. *Tetra-hydride* $\mathrm{NPh}\!<\!\begin{smallmatrix}\mathrm{CH_2.S}\\ \mathrm{CH_2.CH_2}\end{smallmatrix}$. Got by reducing ethylene phenyl-di-thio-carbamate [128°] with tin and HCl (Förster, *B.* 21, 1871). Oil.—B′$_2$H$_2$PtCl$_6$.

Di-phenyl-thiazole $\mathrm{N}\!<\!\begin{smallmatrix}\mathrm{CPh.S}\\ \mathrm{CPh:CH}\end{smallmatrix}$ [93°]. (above 360°). Got from thiobenzamide and bromo-acetophenone in alcohol (Hubacher, *A.* 259, 237). Plates, v. sol. alcohol and ether.

Tri-phenyl-thiazole $\mathrm{N}\!<\!\begin{smallmatrix}\mathrm{CPh.S}\\ \mathrm{CPh:CPh}\end{smallmatrix}$ [87°]. Got from thiobenzamide and bromo-deoxybenzoïn (Hubacher, *A.* 259, 245). Prisms (from ether), m. sol. alcohol, nearly insol. HClAq.

Reference.—OXY-PHENYL-THIAZOLE.

PHENYL-DITHIENYL $C_4H_3S.C_4H_2PhS$. [209°]. A product of the action of S on toluene at a red heat (Renard, *C. R.* 111, 48). Plates, v. sl. sol. alcohol and ether. Gives a blue colour with isatin and H_2SO_4, and a green colour with phenanthraquinone and H_2SO_4. Gives rise to $C_{14}H_7Br_5S_2$ [320°] and $C_{14}H_8(NO_2)_2S_2$ [273°].

PHENYL THIENYL KETONE *v.* THIENYL PHENYL KETONE.

(α)-PHENYL-(β)-THIO-ALLOPHANIC ACID *Ethyl ether.* $C_{10}H_{12}N_2SO_2$ *i.e.* $NH_2.CS.NPh.CO_2Et$. [127°]. Formed from NHAc.CS.NHPh and $ClCO_2Et$ (Seidel, *J. pr.* [2] 32, 275). Monoclinic tablets, converted by alcoholic NH_3 at 100° into phenyl-thio-urea.

(β)-Phenyl-thio-allophanic acid. *Ethyl ether* $NHPh.CS.NH.CO_2Et$. Got from phenyl-thio-urea and $ClCO_2Et$ (Seidel, *J. pr.* [2] 32, 270). Oil. AcCl at 60° forms NHAc.CS.NHPh [170°].

Phenyl di-thio-allophanic acid. *Isoamyl ether* $NHPh.CS.NH.CO.SC_5H_{11}$. [102°]. Formed from phenyl-thio-urea and $Cl.CO.SC_5H_{11}$ (Schöne, *J. pr.* [2] 32, 256). Needles. Very unstable. Forms an acetyl derivative [240°].

Di-phenyl-thio-allophanic acid. *Ethyl ether* $NHPh.CS.NPh.CO_2Et$. [95°]. Formed from di-phenyl-thio-urea and $ClCO_2Et$ (Seidel, *J. pr.* [2] 32, 262). Prisms (from alcohol). Alcoholic $AgNO_3$ ppts. $C_{16}H_{16}N_2SO_2AgNO_3$.

Reactions.—1. *Caustic potash* regenerates $CS(NHPh)_2$.—2. Aqueous ammonia at 100° forms $NHPh.CS.NH_2$ and $NHPh.CO_2Et$. — 3. Alcoholic *aniline* at 100° forms $CS(NHPh)_2$ and $NHPh.CO_2Et$.—4. HgO in presence of alcoholic ammonia forms $(NHPh.CO.NPh.CO_2Et)_2HgO$ [129°], a crystalline body that is reconverted by H_2S into di-phenyl-thio-allophanic ether.—5. By heating in a current of HCl it is converted into $CS(NHPh)_2$, aniline, and phenyl-thiocarbimide.

Di-phenyl-di-thio-allophanic acid. *Isoamyl ether* $NPhH.CS.NPh.CO.SC_5H_{11}$. [87°]. Got from di-phenyl-thiurea and $Cl.CO.SC_5H_{11}$ (Schöne, *J. pr.* [2] 32, 258). Needles (from alcohol). It is insoluble in cold water, but decomposed by hot water. Its alcoholic solution is ppd. by $AgNO_3$, $HgCl_2$ or $PtCl_4$. HgO and NH_3

convert it (in alcoholic solution) into di-phenyl-guanidine, [147°].

TRI-PHENYL-THIO-AMMELINE $C_{21}H_{17}N_5S$ *i.e.* $C(SH)\left\langle\begin{matrix}N-C(NPh)\\NPh.C(NPh)\end{matrix}\right\rangle NH$. [238°]. Formed from phenyl-cyanamide and phenyl-thiocarbimide, and got also by heating tri-phenyl-biguanide with CS_2 at 100°, and by heating di-phenyl-guanidine with phenyl-thiocarbimide, alcohol, and mercury sulphocyanide (Rathke, *B.* 20, 1065; 23, 1673). Plates (from chloroform). Converted by alcoholic potash into tri-phenyl-ammeline. Alcohol and EtBr at 100° form $C_{21}H_{16}EtN_5SHBr$, crystallising from alcohol in plates.—B'HCl.—$AgC_3HPh_3N_5S$: yellow pp.

DI-PHENYL-THIO-BENZAMIDE $Ph.CS.NPh_2$. Formed by heating di-phenyl-benzamidine with H_2S or CS_2 at 130° (Bernthsen, *A.* 192, 88). Yellow triclinic crystals (from benzene); $a:b:c = \cdot927:1:\cdot766$, $\alpha = 93° 29'$, $\beta = 100° 55'$, $\gamma = 84° 14'$. Insol. cold water, sl. sol. cold alcohol.

PHENYL-DI-THIO-BIURET $C_8H_9N_3S_2$ *i.e.* $NHPh.CS.NH.CS.NH_2$. [174°]. Formed by heating aniline with perthiocyanic acid (Glutz, *A.* 154, 44). Got also by boiling carbimido-phenyl-thio-urea with ammonium sulphide (Wunderlich, *B.* 19, 452). Prepared by adding phenyl-thiocarbimide (36 g.) to an alcoholic solution of cyanamide (11 g.) and Na (6 g.), and decomposing the pp. by dissolving in a solution of NH_4Cl (14·5 g.) containing NH_3Aq (50 c.c.), passing in H_2S, and heating to boiling (Hecht, *B.* 25, 756). Pearly plates, sl. sol. hot water.—B'HCl.—$B'HNO_3$.

Ethyl derivative $C_8H_8EtN_3S_2$. [109°]. Got by adding alcohol, NH_3Aq, and EtI to the base (Tursini, *B.* 17, 584). Trimetric tables.

PHENYL-THIO-CARBAMIC ACID NHPh.CO.SH. *Methyl ether* NHPh.CO.SMe. [84°]. Formed by heating di-phenyl-methyl-ψ-thio-urea NHPh.C(NPh).SMe with dilute H_2SO_4 (Will, *B.* 15, 339). Plates, sol. alcohol, ether, and benzene. Decomposed by KOH into aniline, MeSH, and CO_2. Boiling alcoholic NH_3 forms MeSH and phenyl-urea. Aniline gives methyl mercaptan and $CO(NHPh)_2$.

Ethyl ether NHPh.CO.SEt. [73°]. Needles. Got by heating NHPh.C(NPh).SEt with dilute H_2SO_4 and by the action of aniline on Cl.CO.SEt (Will).

Isoamyl ether $NHPh.CO.SC_5H_{11}$. [67°]. Got from aniline and $Cl.CO.SC_5H_{11}$ (Schöne, *J. pr.* [2] 32, 249). Needles (from ether).

Ethylene ether $CO\left\langle\begin{matrix}NPh.CH_2\\S-CH_2\end{matrix}\right.$. [79°]. Got by heating di-phenyl-ethylene-ψ-thio-urea with dilute HClAq at 200° (W.). Formed also by the action of chloro-acetic acid on the ethylene ether of phenyl-di-thio-carbamic acid (Evers, *B.* 21, 976). Needles, sol. alcohol and ether, insol. acids and alkalis.

Phenyl ether NHPh.CO.SPh. [125°]. Formed by heating phenyl mercaptan with phenyl cyanate (Snape, *C. J.* 47, 778; *B.* 18, 2432). Needles, v. sol. alcohol and ether.

Phenyl-ψ-thio-carbamic acid NHPh.CS.OH.

Ethyl ether $C_9H_{11}NSO$ *i.e.* NHPh.CS.OEt or NPh:C(SH).OEt. [72°]. Formed by heating phenyl-thiocarbimide with alcohol (Hofmann, *B.* 2, 120; 3, 772; Bamberger, *B.* 15, 2164). Formed also by the action of alcoholic potash on phenyl-thiocarbimide (R. Schiff, *B.* 9, 1316). Triclinic prisms, sol. alkalis and reppd. by CO_2. Resolved by distillation into alcohol and phenyl-thiocarbimide. Oxidised by alkaline K_3FeCy_6 to $C_{18}H_{20}N_2O_2S_2$ or $S_2(C(NPh).OEt)_2$ [102°], which is also got by the action of I on $C_9H_{10}NOSAg$ (Liebermann a. Natanson, *B.* 13, 1575; Jacobsen, *B.* 19, 1076).—$(C_9H_{10}NO.S)_2Pb\,2aq$: small needles.—$C_9H_{10}NOSAg$.—$C_9H_{10}NOSHgClHCl$: needles.—$(C_9H_{10}NOS)_2Hg$. [78°] (Stephanovitch, *B.* 7, 692).—$(C_9H_{10}NOS)_2HgAgNO_3$. Needles.—$C_9H_{10}NOSMe$. (260°–265°). Oil.—$C_9H_{10}NOSEt$. [30°]. (275°). Prisms; decomposed by dilute H_2SO_4 at 200° into aniline and CO(OEt)(SEt) (Liebermann, *B.* 13, 682; *A.* 207, 148).—$C_9H_{10}NOSC_4H_9$. [75°] (Mylius, *B.* 5, 977).

Phenyl ether NHPh.CS.OPh. Got by heating phenyl-thiocarbimide with phenol at 145° (Dixon, *C. J.* 57, 268). Sulphur-yellow octahedra; decomposed by heat.

Phenyl di-thio-carbamic acid NHPh.CS.SH. Splits up into CS_2 and aniline when set free from its salts.

Salts.—The salt NHPh.CS.SK is formed by boiling potassium xanthate EtO.CS.SK (1 mol.) with an alcoholic solution of aniline (1 mol.) (Rathke, *B.* 11, 958). Prepared from CS_2, aniline, ether, and alcoholic potash (Losanitsch, *B.* 24, 3024). Yellow monoclinic needles, v. e. sol. water and alcohol, insol. ether. Yields $CS(NHPh)_2$ when heated. Boiling water forms phenyl-thiocarbimide and $CS(NHPh)_2$.—$NHPh.CS.SNH_4$. Yellow prisms. Converted by I into $(NHPh.CS)_2S$ [138°]. BaA'_2: yellowish plates.—NiA'_2.

Methyl ether NHPh.CS.SMe. [93·5°]. Formed from the NH_4 salt and MeI (L.) and also by heating NHPh.C(NPh).SMe with CS_2 at 160° (Will, *B.* 15, 342). Decomposed by alkalis into MeSH and aniline.

Ethyl ether NHPh.CS.SEt. [60°]. Formed from phenyl-thiocarbimide and mercaptan at 150° (Hofmann, *B.* 2, 120; Will, *B.* 15, 1305), and also by the action of EtI on the ammonium salt (L.). Tables, v. sol. alcohol, sol. alkalis.

Isoamyl ether $C_5H_{11}A'$. [171°].

Ethylene derivative $CS\left\langle\begin{matrix}NPh.CH_2\\S-CH_2\end{matrix}\right.$. [234°]. Formed, together with phenyl-thiocarbimide, by heating $C(NPh)\left\langle\begin{matrix}NPh.CH_2\\S-CH_2\end{matrix}\right.$ with CS_2 at 200° (W.). Needles. Converted by MeI into $C_9H_9NS_2MeI$ [149°].

References.—BROMO-, CHLORO-, and NITRO-PHENYL-THIO-CARBAMIC ACID.

PHENYL-THIOCARBAMINE-CYAMIDE *v.* CARBIMIDO-PHENYL-THIO-UREA.

PHENYL-THIOCARBAMINE-ETHYL-CYAMIDE *v.* ETHYL-CARBIMIDO-PHENYL-THIO-UREA.

PHENYL-THIO-CARBAZIC ACID NHPh.NH.CO.SH. The phenyl hydrazine salt $NHPh.NH.CO.SN_2H_3Ph$ [84°] is formed from phenyl-hydrazine and COS (Heller, *A.* 263, 269).

Phenyl di-thio-carbazic acid NHPh.NH.CS.SH. Formed, as phenyl-hydrazine salt $NHPh.NH.CS.SN_2H_3Ph$ [97°] by adding CS_2 to an ethereal solution of phenyl-hydrazine (Fischer, *A.* 190, 114). Plates, v. sol. alcohol and ether. Readily decomposed by heat into $CS(N_2H_3Ph)_2$, CS_2, H_2S, and NH_3.

PHENYL-THIO-SEMICARBAZIDE $C_7H_9N_3S$ *i.e.* $NH_2.CS.NH.NHPh$. [201°] (F.; P.); [190°] (S. a. R.).

Formation.—1. By warming di-phenyl-thio-carbazide with alcoholic or aqueous alkalis (Fischer, *A.* 212, 324).—2. By heating phenyl-hydrazine sulphocyanide.—3. By heating phenyl-hydrazine with thio-urea or with phenyl-thio-urea (Pellizzari, *G.* 16, 203; Skinner a. Ruhemann, *C. J.* 53, 550; *B.* 20, 3373).

Properties.—Needles, insol. ether, sl. sol. hot water, v. sol. hot alcohol. Conc. HClAq at 120° forms phenyl-thiocarbizine $C_7H_6N_2S$. $COCl_2$ forms $CO:N_2Ph.CS.NH_2$ [c. 270°] crystallising from HOAc (Freund, *A.* 21, 2465).

Acetyl derivative NHPh.NH.CS.NHAc. [179°]. Formed by mixing solutions of acetyl-thiocarbimide and phenyl-hydrazine in dry benzene (Dixon, *C. J.* 55, 303). Small prisms.

Benzoyl derivative $C_{14}H_{13}N_3SO$. Silky needles. Does not melt at 220°.

Di-phenyl-thiocarbazide $CS(NH.NHPh)_2$. [c. 150°]. Formed by heating the compound of phenyl-hydrazine and CS_2 at 110°–140° (Fischer). Formed also from phenyl-hydrazine and $CSCl_2$ (Heller, *A.* 263, 278). Triangular prisms (from alcohol). Dissolves in hot aniline, forming a solution which is green in thin layers, but red in thick layers. Hot alcoholic potash also forms this dichroic substance, di-phenyl-thiocarbazone $C_{13}H_{12}N_4S$ or $CS(N_2Ph)NH.NHPh$, which yields $(C_{13}H_{12}N_4S)_2ZnO$, and may be reduced by zinc-dust and NaOHAq to phenyl-thio-semicarbazide and aniline. Di-phenyl-thio-carbazone may be oxidised by ppd. MnO_2 in presence of alcoholic potash to red needles of di-phenyl-thiocarbodiazone $CS(N_2Ph)_2$.

Di-phenyl-thio-semicarbazide NHPh.NH.CS.NHPh. [177°]. Formed from phenyl-hydrazine and phenyl-thiocarbimide in alcoholic solution (Fischer, *A.* 190, 122). Prisms (from alcohol), sl. sol. ether. $COCl_2$ forms $CO:N_2Ph.CS.NHPh$ [188°], crystallising in needles (Freund, *B.* 21, 2466).

Butyryl derivative $C_4H_7O.NPh.NH.CS.NHPh$. [156°]. Formed from sodium phenyl-hydrazine, phenyl thiocarbimide, and *n*-butyryl chloride (Michaelis a. Schmidt, *A.* 252, 309). V. sol. hot alcohol.

Benzoyl derivative NPhBz.NH.CS.NHPh. [310°]. Obtained from $NPhBz.NH_2$ and phenyl-thiocarbimide (M. a. S.).

Reference.—NITRO-DI-PHENYL-THIO-SEMICARBAZIDE.

DI-PHENYL-THIO-SEMICARBAZIDE CARBOXYLIC ACID $C_{14}H_{13}N_3O_2S$ *i.e.* $NHPh.CS.NH.NHC_6H_4.CO_2H$. [204°]. Formed by warming *m*-hydrazido-benzoic acid with phenyl thiocarbimide and HOAc (Roder, *A.* 236, 173). Colourless needles.

PHENYL-THIOCARBIMIDE C_7H_5NS *i.e.* $C_6H_5N.CS$. Mol. w. 135. (220°) at 750 mm. (Schiff, *B.* 19, 568). S.G. $\frac{4}{4}$ 1·059 (Nasini a. Scala, *G.* 17, 66). S.V. 143·4 (Schiff; Lossen *A.* 254, 73).

Formation.—1. By distilling phenyl-thio-urea with P_2O_5 (Hofmann, *Pr.* 9, 274, 487; *C. J.* 13, 309; *B.* 15, 980).—2. By heating di-phenyl-thio-urea with conc. HClAq at 165° (Merz a. Weith, *Z.* 1869, 589).—3. By the action of I on a benzene solution of tri-phenyl-guanidine (Hofmann, *B.* 2, 453; Rudneff, *J. R.* 10, 184).—4. By heating phenyl cyanate or phenyl-carbamic ether with P_2S_5 at 160° (Michael a. Palmer, *Am.* 6, 258).—5. Formed, together with *o*- or *p*- tolyl-thiocarbimide, by heating phenyl-*o*- or *p*- tolyl-cyanamide ($C_6H_5N:C:NC_7H_7$) with CS_2 at 180°–200° (Huhn, *B.* 19, 2409).

Properties. — Pungent oil, volatile with steam.

Reactions. — 1. *Alcohol* at 100° forms NHPh.CS.OEt, while mercaptan gives rise to NHPh.CS.SEt. — 2. *Alcoholic potash* forms $CS(NHPh)_2$ and $CO(NHPh)_2$. — 3. *Ammonia* forms $CS(NHPh)(NH_2)$, *aniline* gives $CS(NHPh)_2$, and other amines act in like manner.—4. PEt_3 acts violently, and forms $C_{13}H_{20}NPS$, while PMe_3 forms oily $C_{10}H_{14}NPS$, which yields crystalline B'HCl.—5. *Chlorine* passed into its solution in chloroform forms $(PhNCS)_2Cl_2$ [150°–160°] and $PhNCCl_2$ (212°). The chloride $(PhNCS)_2Cl_2$ is converted by H_2S into $CS(NHPh)_2$, and by warm spirit into $(PhNCS)_2O$, crystallising in yellow needles [118°] (Helmers, *B.* 20, 786). 6. *Bromine* in chloroform or HOAc forms red crystals of $(PhNCSBr_2)_2$, decomposed at 100° into pale-yellow plates $(PhNCSBr)_2$ [190°] (Helmers; *cf.* Proskauer a. Sell, *B.* 9, 1262).—7. SO_3 forms $C_7H_5NS_2O_3$ [180°–183°], crystallising from benzene, and converted by water at 100° into amido-benzene *p*-sulphonic acid, CO_2, and H_2S (Magatti, *B.* 11, 2267).—8. PCl_5 at 100° forms $C_6H_5NCCl_2$ and $C_6H_4{<}\genfrac{}{}{0pt}{}{N}{S}{>}CCl$ (248°) (Hofmann, *B.* 12, 1126).—9. $ClSO_3H$ forms $C_{14}H_{10}N_2S_3$ [151°], insol. water, and $SO_3H.C_6H_4.NOS$ aq, sol. water (Pawlewski, *B.* 22, 2200).—10. Reduced *copper* at 200° forms benzonitrile.—11. H_2S forms phenyl-thio-urea. — 12. Boiling *water* forms $CS(NHPh)_2$, CO_2, and H_2S (Bamberger, *B.* 14, 2642). — 13. HOAc forms, on heating, $CO(NHPh)_2$, Ac_2O, H_2S, and CO_2; the di-phenyl-urea being further split up into aniline and CO_2, with formation of Ac_2O (Cain a. Cohen, *C. J.* 59, 327; *cf.* Gumpert, *J. pr.* [2] 32, 294).—14. *Chloro-acetic acid* and alcohol at 170° form $PhN:C{<}\genfrac{}{}{0pt}{}{S.CH_2}{O.CO}$ [148°], which yields aniline, CO_2, and thioglycollic acid on boiling with water (Liebermann a. Voeltzkoff, *B.* 13, 276).—15. *Sodium malonic ether* in presence of alcohol forms $C_{14}H_{16}SNO_4Na$, whence acids liberate $C_{14}H_{17}SNO_4$, or $(CO_2Et)_2CH.CS.NHPh$ [60°] (Michael, *J. pr.* [2] 35, 451).—16. *Sodium cyanamide* and alkyl iodides form cyano-phenyl-alkyl-thio-ureas (Hecht, *B.* 23, 1664). In this way the following compounds may be prepared: NHPh.CS.NMeCy [186°], NHPh.CS.NEtCy [144°], $NHPh.CS.NCyC_3H_5$ [100°], crystallising in needles, $NHPh.CS.NCyC_3H_7$ [108°], crystallising in needles, and $NHPh.CS.NCy.CH_2Ph$ [182°]. 17. *Aldehyde-ammonia* forms $C_{22}H_{21}N_3S_2O_2$ [148°], crystallising from alcohol in silvery needles (R. Schiff, *B.* 9, 567; *G.* 6, 244).—18. *Benzamidine* hydrochloride and dilute NaOHAq form CPh(NH).NH.CS.NHPh [125°] (Pinner, *B.* 22, 1609). Prisms.

References.—BROMO-, CHLORO-, IODO-, NITRO-, and OXY- PHENYL-THIOCARBIMIDE.

PHENYL-THIOCARBIZINE $C_7H_6N_2S$ *i.e.* $CS{<}\genfrac{}{}{0pt}{}{NH}{NPh}$. [129°]. Formed by heating phenyl-thio-semicarbazide (10 g.) with dilute (20 p.c.) HClAq (80 c.c.) for 12 hours at 130° (E. Fischer, *A.* 212, 826). Plates (from water), v. e. sol. alcohol. May be distilled. MeI forms $C_7H_5MeN_2S$ [123°]. Does not reduce Fehling's solution. HIAq at 200° forms aniline, H_2S, CO_2, and NH_3. Aqueous NaOCl forms a violet pp. which dissolves in H_2SO_4 with deep-red colour. Br in chloroform gives $C_7H_5BrN_2S$ [210°] crystallising in needles.

Salts. — B'HCl. [240°]. Needles. — $B'_2H_2PtCl_6$. Yellow prisms.—$C_7H_5N_2SAg$: flocculent pp. got by adding ammoniacal $AgNO_3$.

Acetyl derivative $C_7H_5AcN_2S$. [187°]. Got by heating phenyl-thiocarbizine with Ac_2O (F.). An isomeride [74°] (275°), got by heating acetyl-phenyl-hydrazine with $CSCl_2$ and benzene (Freund, *B.* 21, 2468), is converted by boiling with alcohol and HgO into acetyl-phenyl-carbizine.

Benzoyl derivative $C_7H_5BzN_2S$. [180°]. Got from the base and BzCl (Fischer). An isomeride [110°] is got by heating NHBz.NPhH with $COCl_2$ in benzene at 100° (F.).

PHENYL THIOCARBONATE $CS(OPh)_2$. [97°]. Formed from NaOPh and $CSCl_2$ (Bergreen, *B.* 21, 346). White crystals, sol. alcohol.

PHENYL-TRI-THIO-ORTHOFORMATE $CH(SPh)_3$. [40°]. Got by boiling aqueous NaSPh with chloroform (Gabriel, *B.* 10, 185). Thick prisms, sol. ether. Split up by fuming HClAq at 100° into formic acid and PhSH.

PHENYL-THIOGLYCOLLIC ACID $C_8H_8SO_2$, *i.e.* $CH_2(SPh).CO_2H$. [62°]. Formed by saponifying its ether, which is got by adding $ClCO_2Et$ to a solution of NaSPh in absolute alcohol (Claesson, *Bl.* [2] 23, 441; Gabriel, *B.* 12, 1639). Thin tables, sl. sol. cold water. Oxidised by $KMnO_4$ to phenyl methyl sulphone (Otto, *B.* 19, 3138). *Salts.*—KA'.—NaA'.—BaA'_2.—CaA'_2.—MgA'_2 3aq.—CdA'_2 aq.—ZnA'_2 2aq.—PbA'_2. [60°].—MnA'_2 5aq.—CuA'_2.—AgA' aq: crystalline pp.

Ethyl ether EtA'. (277°). S.G. $\frac{0}{4}$ 1·136; ^{15} 1·127.

Amide. [104°]. Tables (from alcohol).

References. — Amido- and Bromo- Phenyl-thioglycollic acids.

(a)-PHENYL-THIOHYDANTOÏC ACID $C_9H_{10}N_2SO_2$, *i.e.* $NH_2.C(NPh).S.CH_2.CO_2H$. [148°–152°]. Got by heating aniline with ammonium sulphocyanide, chloro-acetic acid, and alcohol (Claesson, *B.* 14, 732). Needles (from HOAc); m. sol. hot water and ether. Cold NaOHAq converts it into $C_{18}H_{17}N_3S_2O_4$ [112°–115°] (Liebermann, *A.* 207, 129).

(β)-Phenyl-thio-hydantoïc acid $NHPh.C(NH).S.CH_2.CO_2H$. Got by evaporating an alcoholic solution of ammonium chloro-acetate and phenyl-thio-urea at 100° (Meyer, *B.* 14, 1659). Decomposes on heating without melting. Insol. water, alcohol, and ether. Boiling dilute HCl forms $CO\left<\begin{array}{l}NPh.CO\\S—CH_2\end{array}\right.$ [148°].

Isomeride *v.* Phenyl-thio-hydantoïn.

Di-phenyl-hydantoïc acid $NHPh.C(NPh).S.CH_2.CO_2H$. Got from potassium chloro-acetate and di-phenyl-thio-urea (Lange, *B.* 12, 597). Yellow octahedra.

PHENYL-THIO-ψ-HYDANTOÏN $C_9H_8N_2OS$, *i.e.* $C(NH)\left<\begin{array}{l}NPh.CO\\S=CH_2\end{array}\right.$. [178°]. Got from chloro-acetic anilide and thio-urea, and obtained also by boiling (β)-phenyl-hydantoïc acid with HOAc or conc. NH_3Aq (Meyer, *B.* 14, 1661), and by the action of phenyl-cyanamide on thioglycollic acid (Andreasch, *B.* 15, 324). Needles, sol. NaOHAq.

Phenyl-thio-hydantoïn $CS\left<\begin{array}{l}NPh.CO\\NH.CH_2\end{array}\right.$. Got by melting glycocoll with phenyl-thiocarbimide (Aschan, *B.* 17, 424). Monoclinic plates, decomposing near 200°. Boiling alcoholic potash converts it into a salt of an oily phenyl-thio-hydantoïc acid $NHPh.CS.NH.CH_2.CO_2H$ which, when set free, rapidly changes again to phenyl-thio-hydantoïn.

Di-phenyl-thio-hydantoïn $C_{15}H_{12}N_2SO$, *i.e.* $CS\left<\begin{array}{l}NPh.CO\\NPh.CH_2\end{array}\right.$? [176°]. Got from chloro-acetic acid and di-phenyl-thio-urea (Lange, *B.* 12, 595). Iridescent plates, insol. water, v. sol. hot alcohol. Boiling dilute HClAq forms the compound $C_9H_7NSO_2$ [148°].—$B'_2H_2PtCl_6$. Yellow needles.

Di-phenyl-thio-hydantoïn $CS\left<\begin{array}{l}NPh.CO\\NH.CHPh\end{array}\right.$. [233°]. Formed by the action of alkalis on $NHPh.CS.NH.CHPh.CO_2Et$ (Kossel, *B.* 24, 4152).

Reference.—Oxy-di-phenyl-thiohydantoïn.

PHENYL-DI-THIO-DI-METHYL-KETURET $NH\left<\begin{array}{l}CHPh.S\\C(NH).S\end{array}\right>CMe_2$. [239°]. Formed from phenyl-di-thio-biuret and acetone (Fromm, *B.* 25, 1278). Sol. alkalis. Converted by benzyl chloride into $C_7H_7N\left<\begin{array}{l}CHPh—S\\C(NC_7H_7).S\end{array}\right>CMe_2$ [128°] which is insol. alkalis.

DI-PHENYL-THIO-OXAMIDE $C_2S_2(NHPh)_2$. [133°]. Formed from di-phenyl-oxamide by successive treatment with PCl_5 and H_2S (Wallach, *B.* 13, 527). Golden plates.

(a)-PHENYL-THIOPHENE $C_{10}H_8S$ *i.e.* C_4SH_3Ph. [41°]. Formed by heating either $CH_2Bz.CH(CO_2H)_2$ or β-benzoyl-propionic acid with P_2S_5 (Kues a. Paal, *B.* 19, 3141). Small tables, insol. water, v. e. sol. ether, v. sol. alcohol. Volatile with steam. With isatin and cold H_2SO_4 it gives a splendid bluish-violet colour, changing to dark blue. Bromine gives rise to $C_{10}H_6Br_2S$ [56°] and $C_4SBr_3.C_6H_4Br$ [1:4] [146°].

(β)-Phenyl-thiophene C_4H_3PhS. [170°]. (330°). A product of the passage of the vapours of toluene and sulphur through a red-hot tube (Renard, *C. R.* 109, 699). White spangles, m. sol. cold alcohol. Gives a blue colour with isatin and H_2SO_4, and a green colour with phenanthraquinone and H_2SO_4. Yields $C_4H_2BrS.C_6H_4Br$ [1:4] [195°], $C_4H_2(NO_2)S.C_6H_4.NO_2$ [1:4] [178°], a di-sulphonic acid, and a tetrasulphonic acid.

Di-(a)-phenyl-thiophene $S\left<\begin{array}{l}CPh:CH\\CPh:CH\end{array}\right.$. [153°] Formed by heating $C_2H_4Bz_2$ with P_2S_5 at 180° (Paal, *B.* 21, 3058). White plates (from alcohol).

Tri-phenyl-thiophene C_4Ph_3HS. [127°]. Got by heating desyl-acetophenone with P_2S_5 at 150° (A. Smith, *C. J.* 57, 647). Plates, v. sol. benzene. Gives a greenish-yellow colour with H_2SO_4 and isatin or phenanthraquinone.

Tetra-phenyl-thiophene $C_{28}H_{20}S$ *i.e.* $S\left<\begin{array}{l}CPh:CPh\\CPh:CPh\end{array}\right.$. *Thionessal.* [182°].

Formation.—1. By the dry distillation of thiobenzoic aldehyde (Laurent, *A.* 52, 354).—2. By distilling benzyl sulphide or benzyl disulphide (Märcker, *A.* 136, 94).—3. By distilling benzylidene sulphide (Fleischer, *A.* 140, 239; 144, 194).—4. By distilling barium phenyl-acetate with S (Forst, *A.* 178, 376).—5. By heating phenyl-acetic acid with S for 6 hours at 260° (Ziegler, *B.* 23, 2473).—6. By heating phenyl benzyl ketone with S.—7. By heating *s*-di-phenyl-ethylene with S at 250° (Baumann a. Klett, *B.* 24, 3311). Minute needles, sl. sol. alcohol, v. sol. benzene and CS_2. Yields a sulphonic acid, and also the following derivatives: $C_{28}H_{18}Cl_2S$ [219°] (Dorn, *A.* 153, 350), $C_{28}H_{17}Br_3S$ [265°–270°], $C_{28}H_{16}(NO_2)_4S$ [above 250°].

DI-PHENYL-DI-THIO-DI-PHENYL-KETATE $CPh_2(SPh)_2$. *Phenyl-mercaptol of benzophenone.* [139°]. Formed by passing HCl gas into a hot mixture of benzophenone, phenyl-mercaptan, and $ZnCl_2$ (Baumann, *B.* 18, 888). Short prisms, sl. sol. alcohol and ether.

PHENYL THIOPHOSPHATE $PS(OPh)_3$. [49°]. (above 360°). Got by boiling $PSCl_3$ with phenol (Schwarze, *J. pr.* [2] 10, 222) and by heating phenyl phosphate with K_2S (Kreysler, *B.* 18, 1718), or with S at 190° (Anschütz, *A.* 253, 118). Needles (from alcohol), turning red in air and light. Not decomposed by water.

Phenyl tri-thiophosphate $PO(SPh)_3$. [72°]. Got by boiling PhSH with $POCl_3$. Prisms (from alcohol). Decomposed by warm water.

Phenyl tetra-thio-phosphate $PS(SPh)_4$. [86°]. Got from PhSH and $PSCl_3$. Silky white needles, not affected by boiling water.

PHENYL THIOSULPHURIC ACID $C_6H_5.S.SO_2.OH$. *Phenyl hydrogen thiosulphate.* Got by dissolving Ph_2S in H_2SO_4 (Stenhouse, *Pr.* 17, 62; *A.* 149, 254).—BaA'_2 2aq: crystalline.

PHENYL-THIO-URAMIDO-ACETIC ORTHALDEHYDE. *Di-ethyl derivative* $NHPh.CS.NH.CH_2.CH(OEt)_2$. [96°]. Got by mixing phenyl-thiocarbimide with amido-acetal $NH_2.CH_2.CH(OEt)_2$ (Wohl a. Marckwald, *B.* 22, 569). Needles (from dilute alcohol), insol. water and ligroïn, v. sol. ether. Cold conc. H_2SO_4 forms $NHPh.CS.NH.CH_2.CH(OH)(OEt)$ [94°] which yields, by loss of H_2O, the salts $(C_{11}H_{14}N_2SO)_2H_2PtCl_6$ and $C_{11}H_{14}N_2SOC_6H_3N_3O_7$ [190°].

PHENYL-THIO-URAMIDO-BENZOIC ACID *v.* *m*-AMIDO-BENZOIC ACID.

***o*-PHENYL-THIO-URAMIDO-CINNAMIC ACID** $NHPh.CS.NH.C_6H_4.CH:CH.CO_2H$. [237°]. Formed by heating *o*-amido-cinnamic acid with phenyl-thiocarbimide on the water-bath (Rothschild, *B.* 23, 3343).

DI-PHENYL-DI-THIOURAMIDO-TETRA-OXY-DI-PHENYL. *Tetra-methyl derivative* $C_{12}H_4(OMe)_4(NH.CS.NHPh)_2$. [184°]. Formed from $C_6H_2(OMe)_2(NH_2).C_6H_2(OMe)_2(NH_2)$ and phenyl thiocarbimide (Baessler, *B.* 17, 2128). White flakes, sol. hot alcohol and benzene.

PHENYL-THIOURAMIDO-PHENYL-ACETIC ETHER $NHPh.CS.NH.CHPh.CO_2Et$. [162°]. Formed from phenyl-amido-acetic ether and phenyl-thiocarbimide (Kossel, *B.* 24, 4151). White crystals, sol. hot alcohol.

PHENYL-THIO-URAMIDO-THIO-FORMIC ACID *v.* PHENYL-DI-THIO-ALLOPHANIC ACID.

PHENYL-THIOURAMIDO-TOLYL-CARBAMIC ETHER $NHPh.CS.NH.C_6H_3Me.NH.CO_2Et$. [155°]. Formed, together with $CS(NHPh)_2$, by the action of phenyl-thiocarbimide on amido-tolyl-carbamic ether (Schiff, *B.* 23, 1818). Prisms (from alcohol), v. sl. sol. alcohol.

DI-PHENYL-DI-*p*-THIOURAMIDO-DI-TOLYL-*o*-SULPHIDE $C_{28}H_{26}N_4S_3$ *i.e.* $S(C_6H_3Me.NH.CS.NHC_6H_5)_2$. *Thio-p-tolyl-di-phenyl-thiourea.* [134°]. Formed by the action of phenyl-thiocarbimide upon di-*p*-amido-di-tolyl-sulphide (Truhlar, *B.* 20, 670). White prismatic needles. V. sol. alcohol, ether, and benzene.

PHENYL-THIO-UREA $C_7H_8N_2S$ *i.e.* $NHPh.CS.NH_2$. Mol. w. 152. [154°]. S. ·26 at 18°; 5·93 at 100°. S. (alcohol) 5·59 at 16°; 68 at 78°.

Formation.—1. By heating phenyl sulphocyanide with alcoholic NH_3 (Hofmann, *Pr.* 9, 275).—2. By boiling aniline with ammonium sulphocyanide (Schiff, *A.* 148, 338; Rathke, *B.* 18, 3104).—3. By heating aniline sulphocyanide at 190° (Salkowski, *B.* 24, 2728; *cf.* De Clermont, *C. R.* 82, 512).—4. By passing H_2S into a solution of phenyl-cyanamide in benzene (Weith, *B.* 9, 819).

Properties.—Needles, sol. alkalis and reppd. by acids. Tastes bitter.

Reactions.—1. *Heated* in a sealed tube at 180° it yields $CS(NHPh)_2$, ammonium sulphocyanide, NH_3, H_2S, and aniline.—2. *Ammonia* at 140° forms aniline and ammonium sulphocyanide.—3. Boiling *aniline* forms $CS(NHPh)_2$.—4. HClAq at 120° forms aniline, H_2S, NH_3, and CO_2.—5. By boiling with alkaline lead acetate solution it gives phenyl cyanamide $N:C.NHC_6H_5$, which polymerises on heating to tri-phenyl-iso-melamine $(PhN:C)_3(NH)_3$.—6. When boiled for several hours with freshly-precipitated HgO it yields *asymmetrical* tri-phenyl-melamine $PhN{<}\begin{matrix}C(NH).NPh\\C(NH).N\end{matrix}{>}C.NHPh$ (Hofmann, *B.* 18, 3220).—7. $Cl.CO.CO_2Et$ forms oxalyl-di-phenyl-biuret, $NH{<}\begin{matrix}CS.NPh\\CS.NPh\end{matrix}{>}C_2O_2$ (*v.* CHLORO-GLY-OXYLIC ETHER).—8. $ClCO_2Et$ forms phenyl-thio-allophanic ether.—9. *Silicon tetrabromide* gives solid $SiBr_4(C_7H_8N_2S)_4$, sol. hot benzene, but decomposed by boiling alcohol (Reynolds, *C. J.* 53, 856).—10. An alcoholic solution of *allyl bromide* forms a base $C_{10}H_{12}N_2S$ (Werner, *C. J.* 57, 302).—11. *Benzyl chloride* in alcohol forms $CS(N_2H_3Ph)C_7H_7Cl$ [112°] (W.).—12. *Ethylene bromide* forms $C_{16}H_{18}N_4S$ [139°], which gives the salts B″2HBr [214°], B″2HCl [218°], $B''H_2PtCl_6$, and $B''2C_6H_2(NO_2)_3OH$ [196°] (Bertram, *B.* 25, 59).—13. H_2O_2 oxidises it, in alcoholic solution, to di-phenyl-di-amido oiazthiole (Hector, *B.* 22, 1176).

Salts.—$B'_2H_2PtCl_6$.—$B'_6Cu_2Cl_2$ 6aq. [145°] (Rathke, *B.* 17, 305). Trimetric crystals (from alcohol).

Acetyl derivative NHPh.CS.NHAc. [173°]. Formed from acetyl sulphocyanide and aniline (Miguel, *A. Ch.* [5] 11, 318), and by the action of Ac_2O on the product of the action of phenyl thiocarbimide on aldehyde-ammonia (Schiff, *B.* 9, 570). Tables (from dilute alcohol).—B′HBr. [270°]. Prisms, v. e. sol. water.

Benzoyl derivative NHPh.CS.NHBz. [149°]. S. (alcohol) 4 at 78°. Needles, insol. water (Miguel).

o-Oxy-benzoyl derivative $NHPh.CS.NH.CO.C_6H_4OH$. [192°]. Formed from salicyl-thiocarbimide and aniline (M.).

Di-phenyl-thio-urea $C_{13}H_{12}N_2S$ *i.e.* $CS(NHPh)_2$. Mol. w. 228. [151°] (Lellmann, *A.* 221, 21; Losanitsch, *B.* 19, 1821).

Formation.—1. By boiling aniline with CS_2 and alcohol (Hofmann, *A.* 57, 266; 70, 144). 2. By heating aniline with potassium sulphocyanide and H_2SO_4 (Laurent a. Gerhardt, *A. Ch.* [3] 22, 103; 24, 196).—3. From aniline and phenyl-thiocarbimide.—4. From di-phenyl-cyanamide and H_2S (Weith, *B.* 7, 1303).—5. By boiling *s*-di-phenyl-guanidine with CS_2 (Hofmann, *B.* 2, 460).

Properties.—Trimetric crystals (from alcohol), nearly insol. water, v. sol. alcohol and ether. Sol. alkalis and reppd. by acids. Has a very bitter taste.

Reactions.—1. Partially decomposed on *distillation* into tri-phenyl-guanidine, CS_2, and H_2S.—2. P_2O_5, $ZnCl_2$, or HCl split it up into aniline and phenyl-thiocarbimide.—3. Boiling *alcoholic potash* forms di-phenyl-urea.—4. Di-phenyl-urea is formed when the alcoholic solution is boiled with HgO.—5. A cold solution of *nitrous ether* in alcohol forms tri-phenyl-guanidine, phenyl thiocarbimide, and S (Claus, *B.* 4, 143).—6. *Iodine*, added to its boiling alcoholic solution, forms tri-phenyl-guanidine and phenyl thiocarbimide.—7. *Aniline* forms, on heating, tri-phenyl-guanidine and H_2S.—8. *Sodium-amalgam* reduces it to aniline, H_2S, and CH_4 (Merz a. Weith, *Z.* [2] 4, 612).—9. When heated with $HgCl_2$ it yields tri-phenyl-guanidine (Buff, 2, 498).—10. Fuming H_2SO_4 decomposes it on heating, forming aniline, COS, and SO_2 (Fleischer, *B.* 9, 993).—11. $COCl_2$ forms $C_{14}H_{10}N_2SO$ [87°], crystallising in prisms and split up by heat into COS and di-phenyl-cyanamide (Will, *B.* 14, 1486).—12. $CSCl_2$ in benzene forms $C_{14}H_{10}N_2S_3$, crystallising in yellow needles [156°], sl. sol. alcohol. In presence of ether $CSCl_2$ forms $NPh{:}C\left<\begin{matrix}NPh\\ S\end{matrix}\right>CS$ [79°] (Freund a. Wolf, *B.* 25, 1459).—13. H_2S at 170° forms aniline and CS_2 (Weith, *B.* 7, 1304).—14. *Alkyl iodides* form alkyl derivatives, which may perhaps be formulated as derivatives of ψ-thio-urea. Thus, MeI forms $NHPh.C(SMe){:}NPh$ [110°], which is decomposed by heat into MeSH and $C(NPh)_2$, and by alcoholic potash into MeSH and $CO(NHPh)_2$. In like manner EtI forms $C_{15}H_{16}N_2S$ [79°] (*v.* DI-PHENYL-ETHYL-ψ-THIO-UREA), and ethylene bromide gives $C_{15}H_{14}N_2S$ [136°] (Will, *B.* 14, 1490).—15. *Allyl bromide* in alcohol yields $C_{16}H_{17}N_2SBr$, crystallising in trimetric prisms [171°] (Werner, *C. J.* 57, 303).—16. *Benzyl chloride* in alcohol forms $C_{20}H_{19}N_2SCl$, crystallising in prisms [153°] (W.).—17. *Phenyl cyanate* in presence of benzene at 180° forms di-phenyl-urea and phenyl sulphocyanide (Goldschmidt a. Meissler, *B.* 23, 271).—18. Ac_2O yields acetanilide and some phenyl-thiocarbimide (Werner, *C. J.* 59, 398).—19. *Chloro-glyoxylic ether* forms di-phenyl-di-thio-parabanic acid $C_{16}H_{11}N_2S_2O_2$ [215°] and $C_{21}H_{17}N_3S_2O$ [231°], which by boiling with alcohol and $AgNO_3$ is converted into di-phenyl-parabanic acid, aniline, and H_2S, while by boiling alcoholic ammonia it is converted into $C_{14}H_{11}N_4O_2$ [220°], whence fuming HNO_3 forms $C_{13}H_{13}N_5O_6$ [235°]. The compound $C_{21}H_{17}N_3S_2O$ is converted by fuming HNO_3 into $C_{15}H_9N_4SO_4$ [235°] (Stojentin, *J. pr.* [2] 32, 8).

Tri-phenyl-thio-urea $NHPh.CS.NPh_2$. [152°]. Formed by heating phenyl-thiocarbimide with diphenylamine at 280° (Gebhardt, *B.* 17, 2092, 3036). Long white needles, v. sol. hot alcohol.

Tetra-phenyl-thio-urea $CS(NPh_2)_2$. [195°]. Formed by heating tetra-phenyl-guanidine with CS_2 at 270°; the yield being 60 p.c. of the theoretical amount (Bernthsen a. Friese, *B.* 15, 1530). Formed also from $NHPh_2$ and $CSCl_2$ (Bergreen, *B.* 21, 340). Long needles, sol. hot alcohol, insol. alkalis. Yields diphenylamine on heating with diluted (70 p.c.) H_2SO_4.

Di-phenyl-thio-urea *v.* DI-PHENYL-DI-PHENYL-THIO-UREA.

References.—AMIDO-, BROMO-, CHLORO-, IODO-, NITRO-, and OXY- PHENYL-THIO-UREA.

PHENYL-THIO-UREA CARBOXYLIC ACID *v. m*-AMIDO-BENZOIC ACID, *Reaction* 7.

DI-PHENYL-TOLENYL-AMIDINE $C_{20}H_{18}N_2$ *i.e.* $C_6H_4Me.C(NPh).NHPh$. [168°]. Got by warming $C_6H_4Me.C(OEt){:}NH_2Cl$ with aniline and alcohol (Glock, *B.* 21, 2656). Plates (from benzene), v. sol. alcohol.

PHENYL-TOLUENE *v.* METHYL-DIPHENYL.

DI-PHENYL-TOLUIC ALDEHYDE $C_{20}H_{16}O$ *i.e.* $CPh_2H.C_6H_4.CHO$. [–15°]. (190°–195° at 46 mm.). Formed by heating terephthalic aldehyde with benzene and conc. H_2SO_4 at 100° (Oppenheimer, *B.* 19, 2028). Oil. Reduces ammoniacal $AgNO_3$, being itself oxidised to tri-phenyl-methane carboxylic acid. $KMnO_4$ gives tri-phenyl-carbinol *p*-carboxylic acid. Reacts with phenyl-hydrazine. Yields $C_{20}H_{16}ONaHSO_3$, a crystalline pp., sl. sol. water, insol. alcohol.

PHENYL-*o*-TOLUIDINE $C_{13}H_{13}N$ *i.e.* $[1{:}2]C_6H_4Me.NHPh$. [41°]. (305° i.V.) at 728 mm. (Graebe, *A.* 238, 363). Formed, together with $NHPh_2$ and ditolylamine by heating *o*-toluidine with aniline hydrochloride at 280° (Girard a. Willm, *Bl.* [2] 25, 248). Coloured violet-blue by HNO_3.

Phenyl-*m*-toluidine. (300°–305°). Got by heating $[1{:}3{:}5]\ C_6H_3Me(NHPh).OH$ with zinc-dust (Zega a. Buch, *J. pr.* [2] 33, 542). Oil. Coloured green by H_2SO_4 containing HNO_3.

Phenyl-*p*-toluidine $C_7H_7.NHPh$. [87°]. (318° i.V.) at 728 mm. (Graebe, *A.* 238, 363). Formed by distilling tri-tolyl-rosaniline acetate (Hofmann, *A.* 132, 291). Obtained also, together with diphenylamine and ditolylamine by heating *p*-toluidine (1 mol.) with aniline (1 mol.) and HCl (1 mol.) at 230° (De Laire, Girard, a. Chapoteaut, *Bl.* 1867, i. 360; *A.* 140, 347). Prepared by heating phenol with *p*-toluidine and $ZnCl_2$, or *p*-cresol with aniline and $ZnCl_2$ at 200°, or with $SbCl_3$ (Buch, *B.* 17, 2634). Crystals. Coloured blue by HNO_3. With benzoic acid and $ZnCl_2$ at 260° it yields phenyl-methyl-acridine $C_{20}H_{15}N$ (Bonna, *A.* 239, 60). Bromine vapour forms a tetra-bromide [135°], a hepta-bromo-derivative [185°], and a compound $NC_{13}H_{12}Br_7$ or $NC_{13}H_{0}Br_7$ [254°]. Excess of Br at 310° forms $NC_{13}H_2Br_{11}$ [296°] (Bonna). Bromine in HOAc added to an alcoholic solution forms a tetra-bromo-derivative [156°].

Salt.—B'HCl: plates.

Acetyl derivative $C_{13}H_{12}AcN$. [51°]. Yields $C_{13}H_{11}BrAcN$ [72°], crystallising in plates.

Benzoyl derivative $C_{20}H_{17}NO$. Crystals. Yields crystalline $C_7H_6(NO_2).NBz.C_6H_4NO_2$.

Nitrosamine $C_7H_7NPh.NO$. [82°]. Yellow needles (from ligroïn). Br forms $C_{13}H_{11}BrN_2O$ [166°] (Bonna, *A.* 239, 56).

PHENYL-TOLYL-ACETAMIDINE $C_{15}H_{16}N_2$ *i.e.* $CH_3.C(NC_7H_7).NHPh$. [76°]. Formed from acetyl *p*-toluidine by successive treatment with PCl_5 and aniline (Wallach a. Fassbender, *A.* 214, 206).—$B'_2H_2PtCl_6$.

PHENYL-*p*-TOLYL-ACETIC ACID $C_7H_7.CHPh.CO_2H$. [115°]. Formed from *a*-bromo-phenyl-acetic acid, toluene, and zinc-dust (Zincke, *B.* 10, 996; Neure, *A.* 250, 149). Plates (from water), v. sol. alcohol.—KA′ 4aq.—NaA′ 6aq.—CaA'_2 2aq: needles (from dilute alcohol).

Ethyl ether EtA′. [34°]. Plates.

Amide $C_{15}H_{15}NO$. [151°].

Nitrile $C_7H_7CHPh.CN$. [59°].

Phenyl-di-tolyl-acetic acid $C_{22}H_{20}O_2$ [78°–83°]. Got by oxidising $(C_7H_7)_2CPh.CO.C_6H_5$ (Thörner, *A.* 189, 123). Amorphous powder, insol. water, v. sol. alcohol.

PHENYL-TOLYL-AMINE *v.* PHENYL-TOLUIDINE.

PHENYL-*p*-TOLYL-BENZYL-BIURET $NHPh.CO.N(CH_2Ph).CO.NHC_6H_4Me$. [c. 100°]. Formed from *p*-tolyl-benzyl-urea and phenyl cyanate (Kühn a. Henschel, *B.* 21, 505). Needles (from dilute alcohol).

PHENYL-*p*-TOLYL-BENZYL-UREA $C_{21}H_{20}N_2O$. [113°]. Got from *p*-tolyl-benzyl-carbamic chloride and aniline (Hammerich, *B.* 25, 1823). Dimorphous: prisms or plates, sol. ether and alcohol.

PHENYL-DI-*p*-TOLYL-BIURET $C_{22}H_{21}N_3O_2$ *i.e.* $NHPh.CO.N(C_6H_4Me).CO.NHC_6H_4Me$. [140°]. Formed by heating di-*p*-tolyl-urea with phenyl cyanate at 170° (Kühn a. Henschel, *B.* 21, 505). Crystals (from alcohol).

Di-phenyl-tolyl-biuret $NHPh.CO.NPh.CO.NHC_6H_4Me$. [216°]. Got by heating di-phenyl-urea with *p*-tolyl cyanate at 170° (K. a. H.).

PHENYL-*p*-TOLYL-CARBINOL $C_{14}H_{14}O$ *i.e.* $C_6H_4Me.CPhH.OH$. [53°]. Got by reducing phenyl tolyl ketone in alcoholic solution by sodium-amalgam (E. a. O. Fischer, *A.* 194, 265). Stellate groups of needles (from ligroïn).

Di-phenyl-tolyl-carbinol $C_{20}H_{18}O$ *i.e.* $C_6H_4Me.CPh_2.OH$. [150°]. Formed by oxidising di-phenyl-tolyl-methane with CrO_3 and HOAc (F.). Crystals (from ligroïn). May be distilled.

PHENYL-*p*-TOLYL-CARBINOL *o*-CARBOXYLIC ACID. *Lactone v.* TOLYL-PHTHALIDE.

Di-phenyl-tolyl-carbinol carboxylic acid. *Lactone* $\left[5^{2}_{1}\right] C_6H_3Me{<}\begin{matrix}CPh_2\\CO\end{matrix}{>}O$. [147°]. (above 360°). Formed by oxidising di-phenyl-*m*-xylyl-methane with chromic acid mixture (Hemilian, *B.* 16, 2361; 19, 3063). Prisms.

The isomeric $\left[4^{2}_{1}\right] C_6H_3Me{<}\begin{matrix}CPh_2\\CO\end{matrix}{>}O$, [179°], (above 360°), is got by oxidation of di-phenyl-*p*-xylyl-methane, and is accompanied by $[1:2:5]CPh_2(OH).C_6H_3Me.CO_2H$, which yields BaA'_2 and CaA'_2 and does not form a lactone.

PHENYL-*o*-TOLYL-CARBINYLAMINE $[1:2]C_6H_4Me.CHPh.NH_2$. (299°) at 721 mm. Formed by reducing the oxim of phenyl *o*-tolyl ketone dissolved in alcohol by adding sodium-amalgam and HOAc (Goldschmidt a. Stöcker, *B.* 24, 2806). Yields an acetyl derivative [124°].—B′HCl. [249°]. Needles, m. sol. water.

m-**Isomeride.** (299°) at 724 mm. Yields B′HCl [243°] and an acetyl derivative [97°].

p-**Isomeride.** (296°) at 723 mm. Yields an acetyl derivative [131°] and the salts B′HCl [252°], $B'_2H_2PtCl_6$ 2aq [119°], $B'C_4H_6O_6$ [157°], $B'_2C_4H_6O_6$ [73°]. The hydrochloride is converted by potassium sulphocyanide into the compound $C_6H_4Me.CHPh.NH.CS.NH_2$ [101°] and by potassium cyanate into the urea derivative $C_6H_4Me.CHPh.NH.CO.NH_2$ [158°].

PHENYL TOLYL - CARBINYL KETONE CARBOXYLIC ACID $C_{16}H_{14}O_3$ *i.e.* $C_6H_4Me.CH_2.CO.C_6H_4.CO_2H$. [112°]. Formed by heating $C_6H_4{<}\begin{matrix}C(CH.C_6H_4Me)\\CO\text{———}\end{matrix}{>}O$ with KOHAq at 100° (Heilmann, *B.* 23, 3160). Vitreous prisms.—AgA′. Converted by heating with an alcoholic solution of hydroxylamine hydrochloride into $C_6H_4{<}\begin{matrix}C(CH_2.C_6H_4Me)\\CO\text{———}O\end{matrix}{>}N$ [134°].

PHENYL-*o*-TOLYL-CYANAMIDE $NPh:C:NC_6H_4Me$. *Carbophenyltolylimide.* (320°–325° uncor.). Formed by adding HgO to a boiling solution of phenyl-*o*-tolyl-thiourea in dry benzene, the yield being 65 p.c. of the theoretical. Oil. On keeping, it polymerises to a brittle glassy solid [68°–71°]. V. sol. benzene, sl. sol. ether. By boiling with dilute alcohol it is converted into phenyl-*o*-tolyl-urea. H_2S passed into its boiling solution in dry toluene converts it into phenyl-*o*-tolyl-thiourea. Heated with CS_2 at 180°–200° it yields a mixture of phenyl- and *o*-tolyl-thiocarbimides. It combines with *o*-toluidine, forming *u*-phenyl-di-*o*-tolyl-guanidine (Huhn, *B.* 19, 2410).

Phenyl-*p*-tolyl-cyanamide $NPh:C:NC_7H_7$. (325°–330° uncor.). Resembles the preceding isomeride in mode of preparation and properties.

DI-PHENYL-TOLYLENE-TETRA-AMIDO-METHANE $C_{20}H_{20}N_4$ *i.e.* $C_7H_6{<}\begin{matrix}NH\\NH\end{matrix}{>}C(NHPh)_2$(?). [161°]. Formed by heating $C(NPh)_2$ with tolylene-*o*-diamine at 185° (Dahm a. Gasiorowski, *B.* 19, 3057). Needles (from benzene).—$B'_2$3HCl. [174°].—$B'H_2SO_4$.

DI-PHENYL-*m*-TOLYLENE DIAMINE $C_{19}H_{18}N_2$ *i.e.* $[1:3:5]C_6H_3Me(NPhH)_2$. [105°]. Formed by heating orcin (1 pt.) with aniline (4 pts.) and a mixture of $ZnCl_2$ and $CaCl_2$ at 220° (Zega a. Buch, *J. pr.* [2] 33, 542). White needles (from glacial HOAc).

Di-acetyl derivative [160°].

Di-benzoyl derivative [190°].

Dinitrosamine $C_{19}H_{16}N_4O_2$. [170°].

Reference. — DI-NITRO-PHENYL-TOLYLENE-DIAMINE.

PHENYL-*o*-TOLYLENE-GUANIDINE $C_7H_6{<}\begin{matrix}NH\\NH\end{matrix}{>}C:NPh$. [167°]. Mol. w. 229 (calc. 223). Formed from *o*-tolylene-diamine and di-phenyl-cyanamide (Keller, *B.* 24, 2514). Needles (from warm alcohol). Di-*p*-tolyl-cyanamide forms

$C_7H_6{<}\begin{matrix}N\text{———}\\{>}C:NPh\\N\text{———}\end{matrix}{>}C(NHC_7H_7)_2$ [193°], while phenyl cyanide gives the compound

$C_7H_6\left\langle\begin{matrix}N\text{——}CO\\ >C:NPh\\ N\text{——}CO\end{matrix}\right\rangle NPh$ [234°].—B'HCl.—$B'_2H_2PtCl_6$.—$B'_2H_2SO_4$: white needles.

Mono-acetyl derivative. [147°].

Di-benzoyl derivative. [222°]. Prisms.

Nitrosamine $C_{14}H_{12}N_4O$. [125°].

DI-PHENYL-*m*-TOLYLENE-DI-METHYL-DI-AMINE $C_{21}H_{22}N_2$ *i.e.* $C_6H_3Me(NPhMe)_2$. [124°]. Formed from $C_7H_6(NHPh)_2$, NaOH, and MeI (Zega a. Buch, *J. pr.* [2] 33, 546). White laminæ (from HOAc).

DI-PHENYL-*o*-TOLYLENE-DI-THIO-DI-UREA [1:3:4]$C_6H_3Me(NH.CS.NHPh)_2$. [c. 150°]. Formed from tolylene-*o*-diamine and phenyl-thiocarbimide in alcohol (Lellmann, *A.* 221, [illegible]9). Thin plates (from dilute alcohol), v. sol. warm NaOHAq, sl. sol. water.

Di-phenyl-*m*-tolylene-di-thio-di-urea [1:2:4]$C_6H_3Me(NH.CS.NHPh)_2$ [168°]. Formed from tolylene-*m*-diamine and phenyl-thiocarbimide (Lussy, *B.* 8, 670; Gebhardt, *B.* 17, 3046; Billeter a. Steiner, *B.* 18, 3293; 20, 228).

Di-phenyl-*p*-tolylene-di-thio-di-urea [1:2:5]$C_6H_3Me(NH.CS.NHPh)_2$. [181°]. Formed from tolylene-*p*-diamine and phenyl-thiocarbimide in alcohol (Lellmann a. Würthner, *A.* 228, 206). Plates, nearly insol. alcohol.

DI-PHENYL-TOLYLENE-DI-UREA $C_7H_6(NH.CO.NHPh)_2$. [above 300°]. Formed by adding phenyl cyanate to an ethereal solution of tolylene-diamine [99°] (Kuhn, *B.* 18, 1477). White pp. Insol. water, alcohol, ether, and benzene, v. sl. sol. acetic acid. By boiling with aniline it yields *s*-di-phenyl-urea.

PHENYL-*p*-TOLYL-ETHANE $C_{15}H_{16}$, *i.e.* $CH_2Ph.CH_2.C_6H_4Me$. [27°]. (286° uncor.). Formed by reduction of tolyl benzyl ketone by HI and P (Mann, *B.* 14, 1646). White plates.

Phenyl-*p*-tolyl-ethane $CH_3.CHPh.C_6H_4Me$. (279°). Formed from $C_6H_5.C_2H_4Br$, toluene, and zinc-dust (Bandrowski, *B.* 7, 1016). Oil. Yields *p*-benzoyl-benzoic acid on oxidation.

PHENYL-*p*-TOLYL-ETHYLENE $C_{15}H_{14}$, *i.e.* $CHPh:CH.C_6H_4Me$. *Methyl-stilbene.* [120°]. Formed by boiling *p*-tolyl-benzyl-carbinol with dilute H_2SO_4 (Mann, *B.* 14, 1646), and also by distilling *p*-tolyl cinnamate (Anschütz, *C. J.* 47, 898; *B.* 18, 1945). Pearly plates with blue fluorescence, v. sl. sol. alcohol, v. e. sol. ether. Yields $C_{15}H_{14}Br_2$ [187°].

DI-PHENYL-DI-*p*-TOLYL-ETHYLENE OXIDE? $C_{28}H_{24}O$. *Phenyl tolyl* (*a*)*-pinacolin.* [215°]. Formed by the action of zinc and HClAq on phenyl *p*-tolyl ketone in alcohol, and got also by heating a mixture of the ketone with phenyl-tolyl-carbinol, alcohol, and $ZnCl_2$ (Thörner a. Zincke, *B.* 11, 71; *A.* 189, 104). Minute needles, m. sol. hot alcohol. Conc. HClAq at 150° changes it into the isomeric (*β*)-pinacolin $C_6H_5.CO.CPh(C_6H_4Me)_2$ [137°].

PHENYL *p*-TOLYL ETHYLENE DISULPHONE $C_6H_5.SO.C_2H_4.SO_2.C_7H_7$. [162°]. Got by boiling $C_6H_5.SO_2.C_2H_4Cl$ with an alcoholic solution of sodium toluene *p*-sulphinate (Otto, *J. pr.* [2] 30, 199).

PHENYL-TOLYL-ETHYLENE-*ψ*-THIO-UREA $NPh:C\left\langle\begin{matrix}N(C_7H_7)\\ S.CH_2\end{matrix}\right\rangle CH_2$. [128°]. Formed by boiling the methylo-iodide of the ethylene derivative of tolyl-di-thio-carbamic acid with aniline (Will a. Bidschowski, *B.* 15, 1315). Silky plates.

PHENYL-*p*-TOLYL-ETHYL-THIO-UREA $C_{16}H_{18}N_2S$, *i.e.* $NPhEt.CS.NHC_7H_7$. [90°]. Formed from *p*-tolyl-thiocarbimide and ethyl-aniline (Gebhardt, *B.* 17, 2091). Colourless crystals.

***s*-PHENYL-DI-*o*-TOLYL-GUANIDINE** $C_6H_5N:C(NHC_7H_7)_2$. [102°]. Formed by the action of an alcoholic solution of aniline upon di-*o*-tolyl-thiourea in presence of PbO. Got also by the combination of $C_6H_5.N:C:N.C_7H_7$ with aniline (Huhn, *B.* 19, 2412). Felted needles. V. sol. warm alcohol, ether, and benzene.—B'HCl.—$B'_2H_2Cl_2PtCl_4$: orange-yellow tables.

***u*-Phenyl-di-*o*-tolyl-guanidine** $C_7H_7N:C(NHC_6H_5)(NHC_7H_7)$. [112°]. Formed from *o*-toluidine and $C_7H_7N:C:NC_6H_5$ (Huhn). Long needles, v. sol. alcohol. Salts.—B'HCl.—$B'_2H_2PtCl_6$: orange-yellow tables.

***s*-Di-phenyl-*p*-tolyl-guanidine** $C_7H_7N:C:(NHC_6H_5)_2$. [121°]. Formed by the action of an alcoholic solution of *p*-toluidine upon di-phenyl-thiourea in presence of PbO (Hofmann, *B.* 2, 459; Huhn, *B.* 19, 2412). Felted needles. V. sol. alcohol and ether.—B'HCl.—$B'_2H_2Cl_2PtCl_4$: reddish-yellow pp.

***u*-Di-phenyl-*p*-tolyl-guanidine** $C_{20}H_{19}N_3$, *i.e.* $C_6H_5N:C(NHC_6H_5)(NHC_7H_7)$. [127°].

Formation.—1. By heating phenyl-*p*-tolyl-thiourea with an alcoholic solution of aniline in presence of PbO.—2. By the combination of $C_6H_5N:C:NC_7H_7$ with aniline (Huhn, *B.* 19, 2409).—B'HCl.—$B'_2H_2Cl_2PtCl_4$: sparingly soluble pp.

PHENYL TOLYL-IMIDO-BENZYL KETONE $C_6H_5.CO.C(NC_7H_7).C_6H_5$. Formed by heating *o*-toluidine with benzil at 100° (Bandrowski, *M.* 9, 689). Yellow plates (from alcohol).

PHENYL *o*-TOLYL KETONE $C_{14}H_{12}O$ *i.e.* $C_6H_5.CO.C_6H_4Me$ [1:2]. (314°) at 735 mm. (Smith, *B.* 24, 4046); (295°) at 722 mm. (G. a. S.). Formed by the action of $AlCl_3$ on a mixture of *o*-toluic chloride and benzene (Ador a. Rilliet, *B.* 12, 2301; Goldschmidt a. Stöcker, *B.* 24, 2805). Formed also, together with a much larger quantity of the *p*- isomeride, from BzCl, toluene, and $AlCl_3$ (Elbs, *J. pr.* [2] 35, 466). Oil. Yields anthracene on long boiling or on heating with zinc-dust.

syn-Oxim $C_7H_7.\underset{\text{HO.N}}{C}.C_6H_5$. [69°].

anti-Oxim $C_7H_7.\underset{\text{N.OH}}{C}.C_6H_5$. [105°] (S.).

Phenyl-*m*-tolyl ketone $C_6H_5.CO.C_6H_4Me$ [1:3]. (315° i.V.) at 745 mm. S.G. $\frac{17.5}{}$ 1·088. Formed by the action of $AlCl_3$ on a mixture of *m*-toluic chloride, benzene, and $AlCl_3$ (A. a. R.; G. a. S.). Got also by cautious oxidation of phenyl-*m*-tolyl-methane (Senff, *A.* 220, 252). Oil, miscible with alcohol. Reduced by HIAq at 200° to $C_{14}H_{14}$ (269° at 725 mm.).

Oxim. [101°]. Reduced by sodium-amalgam in presence of HOAc to *m*-toluic anilide and $C_6H_4Me.CPhH.NH_2$.

Phenyl-*p*-tolyl ketone $C_6H_5.CO.C_6H_4Me$ [1:4]. [60°]. (327° i.V.).

Formation.—1. Together with the *o*-isomeride by heating benzoic acid with toluene and P_2O_5 at 200° (Kollarits a. Merz, *B.* 6, 446; Thörner, *A.* 189, 83).—2. By oxidising $C_6H_4Me.CPhH_2$ (Zincke a. Plascuda, *B.* 7, 982).—3. By distilling a mixture of calcium *p*-toluate and benzoate (Radziszewski, *B.* 6, 810).—4. By heating BzCl with toluene and zinc at 190° (Grucarevic a. Merz, *B.* 6, 1243).—5. By the action of $AlCl_3$ on a mixture of *p*-toluic chloride and benzene (A. a. R.).—6. From BzCl, toluene, and $AlCl_3$.

Properties.—Prisms, m. sol. alcohol, v. sol. ether. Dimorphous. Yields *p*-benzoyl-benzoic acid on oxidation. Reduced to $C_6H_4Me.CH_2Ph$ by distillation over zinc-dust. Sodium-amalgam forms phenyl-tolyl-carbinol. Zinc and HClAq acting on the alcoholic solution form two pinacolins $C_{28}H_{24}O$. The (α)-pinacolin [215°] may be converted into the (β)-isomeride [137°] by heating with HOAc.

anti-Oxim

$\underset{HO.N}{C_6H_5.\ddot{C}.C_6H_4Me}$. [154°] (Hantzsch, *B.* 23, 2325, 2776; 24, 58; *cf.* Wegerhoff, *A.* 252, 11). Converted by HOAc and HCl into *p*-toluic anilide. Yields an acetyl derivative [124°] and a benzoyl derivative [85°] (Auwers, *B.* 23, 399).

syn-Oxim

$\underset{N.OH}{C_6H_5.\ddot{C}.C_6H_4Me}$. [116°]. Converted by HOAc and HCl into benzoyl-toluidine and some toluic anilide. Yields an acetyl derivative [118°–122°] and a benzyl derivative [51°].

Phenyl *p*-tolyl diketone $C_6H_5.CO.COC_7H_7$. Formed by heating di-bromo-deoxybenzoïn with water at 183° (Bucher, *B.* 22, 2819). Yellow oil, solidified by cold.

References.—Di-amido-, Nitro-, Oxy-amido-, and Oxy- phenyl-tolyl-ketone.

PHENYL TOLYL KETONE CARBOXYLIC ACID *v.* Toluyl-benzoic acid.

Phenyl *p*-tolyl ketone dicarboxylic acid $C_{16}H_{12}O_5$ ***i.e.*** $C_6H_5.CO.C_6H_2Me(CO_2H)_2$ [1:4:2:6]. *Benzoyl-uvitic acid* [245°]. Formed by oxidising phenyl mesityl ketone with dilute HNO_3 (Elbs, *J. pr.* [2] 35, 489). Needles.—Ag_2A''.

An isomeric acid, got by oxidation of phenyl ψ-cumyl ketone $C_6H_5.CO.C_6H_2Me_3$ [5:1:2:4], yields Ag_2A''.

PHENYL-*o*-TOLYL-METHANE $C_{14}H_{14}$ ***i.e.*** $C_6H_5.CH_2.C_6H_4Me$ [1:2]. *o-Benzyl-toluene.* Mol. w. 182. (284°). Formed, together with the *p*-isomeride, by heating benzyl chloride with toluene and zinc-dust (Zincke, *B.* 6, 906; Senff, *A.* 220, 249). Got also from $C_6H_4Me.CH_2Cl$, benzene, and zinc-dust (Barbier, *B.* 7, 1544). Yields anthracene when passed through a red-hot tube.

Phenyl-*m*-tolyl-methane
$C_6H_5.CH_2.C_6H_4Me$ [1:3]. (275° i.V.). S.G. $\frac{17.5}{}$ ·997. Got by reducing the ketone with HI and P (Ador a. Rilliet, *B.* 12, 2300). Prepared by heating ω-chloro-*m*-xylene (1 pt.) with benzene (7 pts.) and $AlCl_3$ (Senff, *A.* 220, 230; *cf.* Barbier, *C. R.* 79, 660). Oil, sol. alcohol and ether. Gives a di-nitro- derivative [141°].

Phenyl-*p*-tolyl-methane
$C_6H_5.CH_2.C_6H_4Me$ [1:4]. (280° i.V.). Formed, with the *o*- isomeride, by heating benzyl chloride with toluene and zinc-dust (Zincke, *B.* 7, 1153; *A.* 161, 93). Formed also by the action of zinc-dust on benzyl chloride (Prost, *Bl.* [2] 46, 248), and by heating phenyl *p*-tolyl ketone with ammonium sulphide and S at 320° (Willgerodt, *B.* 20, 2470). Oil. Yields *p*-benzoyl-benzoic acid on oxidation. Does not form anthracene when passed through a red-hot tube. Yields a disulphonic acid [38°], which gives $K_2A''\,3\frac{1}{2}aq$, $BaA''\,8\frac{1}{2}aq$, and $CuA''\,4\frac{1}{2}aq$.

Phenyl-di-tolyl-methane $CHPh(C_7H_7)_2$. [56°]. Got by heating $(C_7H_7)_2CPh.CO.C_6H_5$ with soda-lime at 300° (Thörner a. Zincke, *B.* 11, 70).

Di-phenyl-*o*-tolyl-methane $C_{20}H_{18}$ ***i.e.*** $(C_6H_5)_2CH.C_6H_4Me$. [59·5°]. (354°). Formed from leucaniline by diazotising and boiling with alcohol (Fischer, *A.* 194, 282; Rosenstiehl a. Gerber, *A. Ch.* [6] 2, 342). Spherical groups of prisms (from MeOH), v. sol. ether. Oxidised by CrO_3 and HOAc to $(C_6H_5)_2C(OH).C_6H_4Me$ [150°].

Di-phenyl-*m*-tolyl-methane. [62°]. (above 360°). Formed by distilling its carboxylic acid with baryta (Hemilian, *B.* 16, 2368). Long thin needles (from alcohol), v. sol. ether. The crystals emit light when powdered. Its dilute solutions fluoresce blue.

Di-phenyl-*p*-tolyl-methane. [71°]. (above 360°). Formed by distilling its *o*-carboxylic acid, and also by the action of P_2O_5 on a mixture of toluene and di-phenyl-carbinol or of benzene and phenyl-*p*-tolyl-carbinol (Hemilian, *B.* 7, 1209; 19, 3066; Fischer, *A.* 194, 263). Needles or prisms, v. sol. hot alcohol.

References.—Di-amido-, Chloro-, Nitro-, Nitro-amido-, and Oxy- phenyl-tolyl-methane.

PHENYL-*p*-TOLYL-METHANE-*o*-CARBOXYLIC ACID $C_6H_4Me.CH_2.C_6H_4.CO_2H$. [134°]. Formed by warming $C_6H_4Me.CO.C_6H_4.CO_2H$ with NH_3Aq and zinc-dust (Gresly, *A.* 234, 236). Needles (from alcohol), nearly insol. water.—BaA'_2: plates, v. sol. water.

Phenyl-tolyl-methane dicarboxylic acid $CO_2H.C_6H_4.CH(C_7H_7).CO_2H$. [154°]. (above 300°). Got by saponifying the nitrile, which is prepared by treating an alcoholic solution of $CN.C_6H_4.CH_2.CN$ with benzyl chloride and KOH (Eichelbaum, *B.* 21, 2679). Prisms, sol. alcohol.

Amide. [224°]. Small plates.

Imide

$C_6H_4<\begin{smallmatrix}CH(C_7H_7)\\CO.NH\end{smallmatrix}>CO$. [176°]. (above 300°). Got by heating the amide with conc. HClAq. Needles, v. sol. alcohol.

Nitrile. [110°]. (above 300°). Plates.

Di-phenyl-*p*-tolyl-methane carboxylic acid $C_6H_4Me.CHPh.C_6H_4.CO_2H$. [155°]. Formed by warming *p*-tolyl-phthalide with benzene and $AlCl_3$ (Gresly, *A.* 234, 242). Needles (from alcohol).—$BaA'_2\,2\frac{1}{2}aq$: sl. sol. water.

Di-phenyl-*p*-tolyl-methane carboxylic acid $CHPh_2.C_6H_3Me.CO_2H$[4:2:1]. [217°]. Formed from di-phenyl-*p*-tolyl-carbinol carboxylic acid, NaOHAq, and zinc-dust (Hemilian, *B.* 16, 2363). Transparent tables, v. sol. alcohol.—BaA'_2 4aq.—AgA′: minute needles, insol. water.

Di-phenyl-*p*-tolyl-methane carboxylic acid $CHPh_2.C_6H_3Me.CO_2H$[4:1:2]. [203°]. Formed from di-phenyl-methyl-phthalide, NaOHAq, and zinc-dust (Hemilian, *B.* 19, 3064). Needles or tables, sol. hot alcohol.—BaA'_2 3aq.—AgA′.

PHENYL-*p*-TOLYL DI-METHYLENE DI-SULPHONE KETONE $C_{16}H_{16}S_2O_5$ ***i.e.*** $C_6H_5.SO_2.CH_2.CO.CH_2.SO_2.C_6H_4Me$. [112°]. Formed from $CH_2Br.CO.CH_2.SO_2.C_6H_4Me$ by treatment with $C_6H_5SO_2Na$ and obtained also from $C_6H_5.SO_2.CH_2.CO.CH_2Br$ and $C_6H_4Me.SO_2Na$ (Otto, *J. pr.* [2] 36, 427). Plates, m. sol. alcohol, v. sol. $CHCl_3$.

PHENYL-*o*-TOLYL-METHYL-PYRROLE $NC_7H_7<\begin{matrix}CPh{:}CH\\CMe{:}CH\end{matrix}$. [44°]. (327°). Formed by heating its carboxylic acid [199°] (Lederer a. Paal, *B.* 18, 2596). Plates, v. e. sol. alcohol.

Phenyl-*p*-tolyl-methyl-pyrrole. [91°]. (above 350°). Got by heating its carboxylic acid [227°]. Tables (from ligroïn).

PHENYL-*o*-TOLYL-METHYL-PYRROLE CARBOXYLIC ACID $C_6H_4MeN<\begin{matrix}CPh{:}CH\\CMe{:}C.CO_2H\end{matrix}$. [199°]. Got by saponifying its ether, which is formed by boiling acetophenone-acetoacetic ether with *o*-toluidine and HOAc (Lederer a. Paal, *B.* 18, 2596). Small prisms (from alcohol).

p-**Isomeride.** [227°]. Made in like manner from *p*-toluidine. Plates, v. sol. alcohol.

Ethyl ether EtA'. [115°]. Crystals.

PHENYL-*o*-TOLYL-METHYL-THIO-UREA $C_{15}H_{16}N_2S$ *i.e.* $NMePh.CS.NHC_7H_7$. [121°]. Formed from methyl-aniline and *o*-tolyl-thiocarbimide (Gebhardt, *B.* 17, 2091, 3035). Plates.

Phenyl-*p*-tolyl-methyl-thio-urea. [124°]. Formed in like manner from *p*-tolyl-thiocarbimide (G.). Small trimetric tables. By distillation with steam it is resolved into the parent substances, which slowly recombine in the distillate.

PHENYL-TOLYL-NAPHTHYL-GUANIDINE $C_{24}H_{21}N_3$ *i.e.* $CN_3H_2Ph(C_7H_7).C_{10}H_7$. [below 60°]. Formed by boiling an alcoholic solution of phenyl-tolyl-thio-urea and naphthylamine with PbO (Tiemann, *B.* 3, 6). Brittle resin, forming a crystalline hydrochloride.

PHENYL-DI-TOLYL-PHOSPHINE $(C_6H_4Me)_2PC_6H_5$. [57°]. Formed from *p*-bromotoluene (2 mols.), $C_6H_5PCl_2$ (1 mol.), and Na (Dörken, *B.* 21, 1512). Crystals, v. sol. ether.

Di-phenyl-tolyl-phosphine $C_6H_4MeP(C_6H_5)_2$. [68°]. Formed from $(C_6H_5)_2PCl$, *p*-bromotoluene, and sodium (Dörken, *B.* 21, 1511). Small prisms. Yields $(C_6H_5)_2PO(C_6H_4Me)$ [130°] and $(C_6H_5)_2PS(C_6H_4Me)$ [139°].

PHENYL-TOLYL-(*a*)-PINACOLIN $C_{28}H_{24}O$ *v.* DI-PHENYL-DI-*p*-TOLYL-ETHYLENE OXIDE.

Phenyl-tolyl-(β)-pinacolin $C_6H_5.CO.CPh(C_7H_7)_2$. [137°]. Formed by the action of AcCl on phenyl tolyl-(*a*)-pinacolin or on phenyl-tolyl-pinacone (Zincke a. Thörner, *B.* 10, 1477; 11, 65, 1396; *A.* 189, 110). Prepared by boiling phenyl *p*-tolyl ketone with alcohol, HClAq, and zinc. Small dimetric tables, sl. sol. cold alcohol. On heating with soda-lime at 300° it yields phenyl-di-tolyl-methane.

PHENYL-TOLYL-PINACONE $C_{28}H_{26}O_2$ *i.e.* $C_7H_7.CPh(OH).CPh(OH).C_7H_7$. [165°]. Formed by treating an alcoholic solution of phenyl *p*-tolyl ketone with zinc and H_2SO_4 (Zincke a. Thörner, *B.* 10, 1476). Minute needles (from alcohol). Decomposed by fusion and by boiling alcoholic potash into phenyl tolyl ketone and phenyl-tolyl-carbinol. Converted into phenyl-tolyl-(β)-pinacolin by heating with dilute H_2SO_4 at 160°, with HOAc at 190°, with AcCl, or with HClAq. Alcoholic HCl in the cold forms phenyl-tolyl-(*a*)-pinacolin.

PHENYL-TOLYL-PROPANE $C_{16}H_{18}$ *i.e.* $CH_3.CHPh.CH_2.C_6H_4Me$. The *o*- (317°), *m*- (312°), and *p*- (303°) compounds are formed by the action of conc. H_2SO_4 on a mixture of styrene and *o*-, *m*-, and *p*-xylene respectively (Kraemer, Spilker, a. Ebenhardt, *B.* 23, 3271). They are oils, miscible with alcohol and ether.

PHENYL-TOLYL-PROPIONIC ACID $CH_2Ph.CH(C_6H_4Me).CO_2H$. *o*- [95·5°], *m*- [80°], *p*- [105°]. Formed from the corresponding nitriles, which are got from the tolyl-aceto-nitriles by treatment with NaOEt and benzyl chloride (Päpcke, *B.* 21, 1331). The *o*-nitrile is an oil (340°–353°); the *m*-nitrile [53°] (350°–360°), and the *p*-nitrile [79°] are crystalline.

Di-phenyl-*p*-tolyl-propionic acid. *Nitrile* $CH_2Ph.CPh(C_6H_4Me).CN$. [121°]. Formed from phenyl-*p*-tolyl-acetonitrile, NaOEt, and benzyl chloride (Neure, *A.* 250, 150). Needles.

DI-PHENYL-TOLYL-PYRROLE $C_{23}H_{19}N$ *i.e.* $NC_7H_7<\begin{matrix}CPh{:}CH\\CPh{:}CH\end{matrix}$. The *o*- [115°] (above 300°) and *p*- [203°] compounds are formed by distilling the corresponding carboxylic acids with lime (Baümann, *B.* 20, 1492; Paal a. Braikoff, 22, 3089). Both crystallise in white needles.

DI-PHENYL-TOLYL-PYRROLE CARBOXYLIC ACID $N(C_7H_7)<\begin{matrix}CPh{:}C.CO_2H\\CPh{:}CH\end{matrix}$. The *o*-acid [227°] and its *p*- isomeride [206°] are got by saponification of the ethers, which melt at 135° and 145° respectively, and are formed by boiling the corresponding toluidine with phenacyl-benzoyl-acetic ether $CH_2Bz.CHBz.CO_2Et$ and HOAc (Paal a. Braikoff, *B.* 22, 3088). Both acids are crystalline and sl. sol. ether.

Di-phenyl-*p*-tolyl-pyrrole dicarboxylic acid $N(C_7H_7)<\begin{matrix}C(C_6H_4.CO_2H){:}CH\\C(C_6H_4.CO_2H){:}CH\end{matrix}$ [253°]. Formed by heating $C_2H_4(CO.C_6H_4.CO_2H)_2$ with *p*-toluidine on a water-bath (Baumann, *B.* 20, 1489). Yellowish needles, v. sol. alcohol and CS_2.

PHENYL *p*-TOLYL SULPHIDE $Ph.S.C_7H_7$. An oil got by the action of NaSPh on *p*-diazo-toluene chloride (Ziegler, *B.* 23, 2471).

Phenyl *p*-tolyl disulphide $Ph.S_2.C_7H_7$. Formed by adding Br to an ethereal solution of PhSH and C_7H_7SH. Got also, together with Ph_2S_2, by heating toluene *p*-sulphinic acid with PhSH (Otto a. Rössing, *B.* 19, 3133). Thick oil, insol. water, scarcely volatile with steam.

PHENYL *p*-TOLYL SULPHONE $C_{13}H_{12}SO_2$ *i.e.* $C_6H_5.SO_2.C_6H_4Me$. [125°]. S. (alcohol) 1·62 at 20°. Formed by the action of P_2O_5 on a mixture of toluene and benzene sulphonic acid, or of benzene and toluene *p*-sulphonic acid (Michael a. Adair, *B.* 11, 116). Formed also from benzene sulphonic chloride, toluene, and $AlCl_3$ (Beckurts a. Otto, *B.* 11, 2068). Prisms or tablets.

PHENYL-*o*-TOLYL-SEMI-THIOCARBAZIDE $C_{14}H_{15}N_3S$ *i.e.* $NHPh.CS.NH.NH.C_6H_4Me$. [146°]. Formed from phenyl-thiocarbimide and *o*-tolyl-hydrazine (A. E. Dixon, *C. J.* 57, 260). Pearly prisms, v. sl. sol. water, v. sol. hot alcohol.

Isomeride $C_6H_4MeNH.CS.NH.NHPh$. [163°]. Formed from *o*-tolyl-thiocarbimide and phenyl hydrazine. Vitreous prisms, v. sl. sol. water.

PHENYL *o*-TOLYL-THIO-UREA $C_{14}H_{14}N_2S$ *i.e.* $NHPh.CS.NHC_6H_4Me$. [140°]. Formed from *o*-tolyl-thiocarbimide and aniline (Staats, *B.* 13, 137) and by passing H_2S into a boiling solution of phenyl-tolyl-cyanamide $NPh{:}C{:}NC_7H_7$ in dry benzene (Huhn, *B.* 19, 2411). Long needles, sl. sol. water. Boiling HClAq (34 p.c.) splits it up into aniline, *o*-toluidine, phenyl-thiocarbimide, and *o*-tolyl-thiocarbimide (Mainzer, *B.* 15, 1419).

HgO, added to its solution in boiling benzene, forms phenyl-tolyl-cyanamide.

Phenyl-*p*-tolyl-thio-urea NHPh.CS.NHC$_6$H$_4$Me. [137°] (S.); [141°] (F. a. W.). Formed from *p*-tolyl-thiocarbimide and aniline (S.), and from phenyl-*p*-tolyl-cyanamide and H$_2$S (H.). Plates, sl. sol. water. Split up by HClAq in the same way as the *o*- isomeride (M.), and decomposed by HgO in like manner. COCl$_2$ passed into its solution in toluene forms

$NPh{:}C\!\left\langle\begin{matrix}N(C_7H_7)\\S\text{———}\end{matrix}\right\rangle\!CO$

[89°], crystallising in white needles (Freund a. Wolf, *B.* 25, 1466).

Tetra-ω-phenyl-di-*o*-tolyl-thio-urea C$_{39}$H$_{32}$N$_2$S *i.e.* (CHPh$_2$.C$_6$H$_4$.NH)$_2$CS. [123°]. Formed from CHPh$_2$.C$_6$H$_4$.NH$_2$ and CS$_2$ (Fischer a. Fränckel, *A.* 241, 368). White needles, insol. cold alcohol.

References.—NITRO- and OXY- PHENYL-TOLYL-THIO-UREA.

PHENYL-*p*-TOLYL-THIO-UREA-ω-CARBOXYLIC ACID. *Nitrile* NHPh.CS.NH.C$_6$H$_4$.CH$_2$.CN. [141°]. Formed by warming phenyl-thiocarbimide with amido-phenyl-acetonitrile (Freund a. Immerwahr, *B.* 23, 2856). With furfuraldehyde it forms NHPh.CS.NH.C$_6$H$_4$.CCy:CH.C$_4$H$_3$O [160°] crystallising from alcohol.

PHENYL-*o*-TOLYL-UREA C$_{14}$H$_{14}$N$_2$O *i.e.* NHPh.CO.NHC$_6$H$_4$Me. [212°]. Formed by boiling NPh:C:NC$_7$H$_7$ with dilute alcohol (Huhn, *B.* 19, 2410). Slender needles.

Phenyl-*m*-tolyl-urea. [165°]. Formed from phenyl cyanate and *m*-toluidine in ether (Buchka a. Schachtebeck, *B.* 22, 840). Needles.

Phenyl-*p*-tolyl-urea. [211°] (H.); [218°] (Freund a. Wolf, *B.* 25, 1467). Formed by boiling phenyl-*p*-tolyl-cyanamide with dilute alcohol (Huhn, *B.* 19, 2408).

Phenyl-di-*p*-tolyl-urea C$_{21}$H$_{20}$N$_2$O. [136°]. Formed from (C$_6$H$_4$Me)$_2$N.COCl and aniline (Hammerich, *B.* 25, 1821). Needles, sol. alcohol.

Di-phenyl-*p*-tolyl-urea NPh$_2$.CO.NHC$_7$H$_7$. [130°]. Formed from NPh$_2$.COCl and *p*-toluidine (Michler, *B.* 9, 713). Needles.

References.—OXY-PHENYL-TOLYL-UREA.

(β)-PHENYL-UMBELLIFERONE C$_{15}$H$_{10}$O$_3$ *i.e.*

$\begin{bmatrix}1\\4\ 2\end{bmatrix}.C_6H_3(OH)\!\left\langle\begin{matrix}CPh{:}CH\\O\text{—}CO\end{matrix}\right.$

[244°]. Prepared by the action of H$_2$SO$_4$ on a mixture of benzoyl-acetic ether and resorcin (Pechmann a. Duisberg, *B*, 16, 2126). Plates (from dilute alcohol).

PHENYL-URAMIDO-ACETO-NITRILE C$_6$H$_5$.CH(CN).NH.CO.NH$_2$. *Phenyl-aceto-nitrile-urea.* [178°] with decomposition. Formed by heating equimolecular quantities of benzaldehyde-cyanhydrin and urea at 100° (Pinner a. Lifschütz, *B.* 20, 2355). Prisms. V. sol. alcohol, m. sol. hot water. By boiling with dilute HCl it is converted into di-oxy-phenyl-glyoxaline

$\left.\begin{matrix}CHPh.N\\C(OH){:}N\end{matrix}\right\rangle C.OH.$

PHENYL-URAMIDO-BENZOIC ACID *v.* vol. i. p. 157.

PHENYL-α-URAMIDO-CROTO-NITRILE C$_6$H$_5$.CH:CH.C(CN)H.NH.CO.NH$_2$. *Phenyl-croto-nitrile-urea.* [160° with decomposition]. Prepared by heating equivalent quantities of cinnamic-aldehyde-cyanhydrin and urea to 96° for several hours; the yield is 40 p.c. of the cyanhydrin (Pinner a. Lifschütz, *B.* 20, 2353). Needles. M. sol. hot alcohol. By boiling with dilute HCl it is converted into di-oxy-styryl-glyoxaline

$CO\!\left\langle\begin{matrix}NH.CH.CH{:}CHPh\\NH.CO\end{matrix}\right.$.

PHENYL-URAMIDO-PHENYL-ACETIC ACID NHPh.CO.NH.CHPh.CO$_2$H. [154°]. Formed by the action of potash on di-phenyl-thiohydantoïn (Kossel, *B.* 24, 4153). Sol. water.

Ethyl ether EtA'. [165°]. Formed from phenyl-amido-acetic ether and phenyl cyanate (K.). Crystalline powder, sol. hot alcohol.

PHENYL-URAMIDO-PROPIONIC ACID C$_{10}$H$_{12}$N$_2$O$_3$ *i.e.* C$_6$H$_5$NH.CO.NH.CH$_2$.CH$_2$.CO$_2$H. [172°]. Formed by heating β-amido-propionic acid with phenyl-urea at 140° (Hoogewerff a. van Dorp, *R. T. C.* 9, 49). Tablets and needles, m. sol. cold alcohol. AcCl forms C$_{10}$H$_{10}$N$_2$O$_2$ [234°] and C$_{10}$H$_9$AcN$_2$O$_2$ [138°]. KOBr and HCl form C$_{10}$H$_{10}$Br$_2$N$_2$O$_3$ [202°] and C$_{10}$H$_9$Br$_3$N$_2$O$_3$ [220°].—KA'.—CaA'$_2$.—AgA'.

Ethyl ether EtA'. [85°]. Needles.

DI-PHENYL-URAZINE C$_{14}$H$_{12}$N$_4$O$_2$ *i.e.*

$NPh\!\left\langle\begin{matrix}NH.CO\\CO.NH\end{matrix}\right\rangle\!NPh.$

[264°]. Formed by heating phenyl semicarbazide at 160° (Pinner, *B.* 21, 2329) or phenyl-carbazic ether at 240° (Heller, *A.* 263, 282). White needles, v. sol. warm HOAc. Yields the acetyl derivatives C$_{14}$H$_{11}$AcN$_4$O$_2$ [173°], C$_{14}$H$_{10}$Ac$_2$N$_4$O$_2$ [153°] and the ether C$_{14}$H$_{11}$EtN$_4$O$_2$ [137°].

PHENYL-URAZOLE *v.* DI-OXY-PHENYL-TRI-AZOLE.

PHENYL-UREA C$_7$H$_8$N$_2$O *i.e.* NHPh.CO.NH$_2$. [147°]. *Formation.*—1. By passing cyanic acid vapour into cooled aniline or from aniline sulphate and potassium cyanate (Hofmann, *A.* 53, 57; 57, 265; 70, 130; 74, 14; Weith, *B.* 9, 810). 2. From aniline and moist cyanogen chloride.—3. From phenyl cyanate and NH$_3$.—4. From mercuric fulminate and aniline (Steiner, *B.* 8, 518). 5. From benzamidoxim, NaOH, and benzene sulphonic chloride (Pinnow, *B.* 24, 4171).

Properties.—Monoclinic needles, v. sol. alcohol and boiling water, sol. ether. Decomposed at 150° into *s*-di-phenyl-urea, CO$_2$, and NH$_3$.

Reactions.—1. Conc. KOHAq yields aniline, NH$_3$, and CO$_2$.—2. *Baryta-water* yields phenyl-biguanide (Emich, *M.* 12, 16).—3. *Aniline* at 190° forms *s*-di-phenyl-urea.—4. Fuming sulphuric acid forms [1:4] C$_6$H$_4$(NH$_2$).SO$_3$H and SO$_3$H.C$_6$H$_4$.NH.CO$_2$H (Hentschel, *B.* 18, 978).—5. ClCO.CO$_2$Et forms phenyl-allophanic ether and phenyl-parabanic acid.

Acetyl derivative NHPh.CO.NHAc. [183°]. Needles (McCreath, *B.* 8, 1181; Kühn, *B.* 17, 2880; Pinnow, *B.* 24, 4171).

Propionyl derivative. [137°]. Prisms.

Benzoyl derivative NHPh.CO.NHBz. [199°]. Silky needles, v. sol. alcohol.

***s*-Di-phenyl-urea** C$_{13}$H$_{12}$N$_2$O, *i.e.* CO(NHPh)$_2$. Mol. w. 212. *Carbanilide.* [235°]. (260°).

Formation.—1. From aniline and phenyl-cyanate (Hofmann, *A.* 57, 266; 74, 15).—2. From aniline and COCl$_2$ (Hofmann, *A.* 70, 138; Hentschel, *J. pr.* [2] 27, 499).—3. By heating di-phenyl-thio-urea with alcoholic potash.—4. By distilling phenyl-urea (H.; Pinnow, *B.* 24, 4172). 5. By dry distillation of aniline oxalate (Hofmann, *Pr.* 15, 335).—6. By heating urea (1 pt.) with aniline (3 pts.) at 160° (Baeyer, *A.* 131, 251) or phenyl-urea (1 mol.) with aniline (1 mol.) at

185° (Weith, *B.* 9, 821).—7. Together with NH_3, benzamide, and benzanilide, by heating di-benzoyl-urea with aniline at 180° (Holleman, *R. T. C.* 10, 72).—8. By the action of an ethereal solution of $ClCO_2CCl_3$ on aniline (Hentschel, *J. pr.* [2] 36, 310).—9. From $NHPh.CO_2Et$ and aniline at 160° or NaOPh at 220°.—10. From $CO(OPh)_2$ and aniline at 150°-180° (Eckenroth, *B.* 18, 516). 11. From $C(OEt)_4$ and aniline at 280° (Bender, *B.* 13, 699).—12. By heating carbamic ether with aniline (3 mols.) at 180°-185° (Smolka, *M.* 11, 200).—13. From benzamidine hydrochloride, phenyl cyanate, and NaOHAq (Pinner, *B.* 22, 1607).

Properties.—Prisms (from alcohol), v. sl. sol. water, v. sol. alcohol and ether. May be distilled.

Reactions.—1. Conc. H_2SO_4 forms CO_2 and $C_6H_4(NH_2)SO_3H$.—2. Alcoholic NH_3 forms urea and aniline (Claus, *B.* 9, 693).—3. PCl_5 forms phenyl cyanate (Weith, *B.* 9, 810). $ClCO_2CCl_3$ also forms phenyl cyanate on heating.—4. P_2O_5 forms phenyl cyanate and aniline.—5. Dry NaOEt at 220° forms aniline and tri-phenyl-guanidine.—6. $ClCO.CO_2Et$ forms di-phenyl-parabanic acid.

Acetyl derivative $NHPh.NPhAc$. [115°]. Laminæ (from water) (McCreath, *B.* 8, 1181).

u-Di-phenyl-urea $NPh_2.CO.NH_2$. [189°]. Formed from $NPh_2.COCl$ [85°] and alcoholic NH_3 at 100° (Michler, *B.* 8, 1665; 9, 396, 715). Needles. Gives a blue colour with H_2SO_4. Split up by distillation into cyanic acid and diphenylamine.

Tri-phenyl-urea $NPh_2.CO.NHPh$. [136°]. Formed by heating a solution of $NPh_2.COCl$, dissolved in chloroform, with aniline at 130° (Michler, *B.* 9, 396, 715). White needles. Resolved by heat into diphenylamine and phenyl cyanate.

Tetra-phenyl-urea $CO(NPh_2)_2$. [183°]. Formed by heating $NPh_2.COCl$ with NPh_2H and zinc-dust (Michler, *B.* 12, 1166). Got also from diphenylamine and $COCl_2$ (Girard a. Willm, *Bl.* [2] 25, 248). Resolved by HClAq at 250° into diphenylamine and CO_2.

References. — Amido-, Bromo-, Chloro-, Chloro-nitro-, Nitro- and Oxy- phenyl-urea.

PHENYL-UREA *m*-CARBOXYLIC ACID $NHPh.CO.NH.C_6H_4.CO_2H$. [270°]. Formed by heating *m*-amido-benzoic acid with phenyl cyanate at 100° (Kühn, *B.* 17, 2882). Prisms, sol. alcohol, sl. sol. ether.

Di-phenyl-urea di-*m*-carboxylic acid $C_{15}H_{12}N_2O_5$, *i.e.* $CO(C_6H_4.NH.CO_2H)_2$.

Formation.—1. By heating *m*-uramido-benzoic acid (Griess, *Z.* 1868, 650; *B.* 9, 796).—2. By heating a mixture of *m*-uramido-benzoic acid with *m*-amido-benzoic acid at 175° (Traube, *B.* 15, 2122).—3. From *m*-amido-benzoic acid and $COCl_2$ (Sarauw, *B.* 15, 44).—4. By boiling $CS(C_6H_4.NH.CO_2H)_2$ with HgO and KOHAq (Griess, *A.* 172, 169).—5. By heating urea with *m*-amido-benzoic acid at 130° (T.).

Properties.—Minute needles, almost insol. water, alcohol, and ether.

Salts.—BaA″ 3aq.—PbA″.—Ag_2A''.

Ethyl ether Et_2A''. [162°]. Needles.

Amide $CO(C_6H_4.NH.CO.NH_2)_2$. Got by heating urea with *m*-amido-benzamide at 140° (Schiff, *A.* 232, 140). White powder, insol. water, decomposing above 270°.

Di-phenyl-urea di-*p*-carboxylic acid. Formed when urea is heated with *p*-amido-benzoic acid (Griess, *J. pr.* [2] 5, 370). Small needles.—BaA″.

TETRA-PHENYL-UVINONE $C_{34}H_{20}O_4$. Formed in small quantity in the preparation of di-phenyl-furfurane by heating di-phenyl-furfurane dicarboxylic acid (Perkin a. Schlosser, *C. J.* 57, 956). Thin yellow needles, not melting at 280°. H_2SO_4 forms a dark-green solution with brick-red fluorescence.

DI-PHENYL-VALERAMIDINE $C_{17}H_{20}N_2$, *i.e.* $C_4H_9.C(NPh).NHPh$. [111°]. Formed by heating isovaleric acid with aniline and PCl_3 at 150° (Hofmann, *J.* 1865, 416). Crystalline, nearly insol. water.

β-PHENYL-*n*-VALERIC ACID $CHPhPr.CO_2H$. [52°]. Formed by heating its nitrile with HClAq at 185° (Rossolymo, *B.* 22, 1235). Needles.

Nitrile $CHPhPr.CN$. (261°). Formed from phenyl-acetonitrile, PrI, and NaOH. Oil.

β-Phenyl-*iso*-valeric acid $C_{11}H_{14}O_2$ *i.e.* $CH_2Ph.CHEt.CO_2H$. (272°). Formed by reduction of phenyl-angelic acid with sodium-amalgam (Baeyer a. Jackson, *B.* 13, 118). Formed also by heating benzyl-ethyl-acetoacetic ether with conc. KOHAq (Anschütz, *A.* 261, 306). Oil.—AgA′.

Chloride (*c.* 147° at 24 mm.). Oil.

Amide $C_{17}H_{19}NO$. [89°]. Monoclinic crystals; *a:b:c* = ·817:1:1·189; β = 70° 28′.

γ-Phenyl-valeric acid $CH_2Ph.CHMe.CH_2.CO_2H$. (176·5° at 15 mm.). Got by potash-fusion from 'diethyl carbobenzonic' acid, which is a product of the action of alcoholic potash on deoxybenzoïn (Anschütz, *A.* 261, 302). Oil, yielding benzoic acid on oxidation.

Ethyl ether $C_{13}H_{18}O_2$. (146° at 15 mm.).

Chloride $C_{11}H_{13}OCl$. (131° at 11 mm.).

Anilide $C_{17}H_{19}NO$. [102°]. Trimetric needles; *a:b:c* = ·685:1: ·608.

δ-Phenyl-valeric acid $CH_2Ph.CH_2.CH_2.CH_2.CO_2H$. [59°]. Formed by reducing $CHPh:CH.CH_2.CH_2.CO_2H$ (Baeyer a. Jackson, *B.* 13, 122). Leaflets, sl. sol. water.

Benzyl ether. (330°-340°). S.G. $\frac{17}{4}$ 1·027. Got by heating benzyl butyrate with Na at 130° (Conrad a. Hodgkinson, *A.* 193, 318). Liquid.

Isomeride *v.* Benzyl-isobutyric acid.

Reference.—Amido-, Di-bromo-, Di-bromo-amido-, Nitro- and Oxy- phenyl-valeric acids.

PHENYL-VINYL- *v.* Styryl-.

DI-PHENYL-VINYL-DIAMINE $C_{14}H_{14}N_2$ *i.e.* $NHPh.CH_2.CH:NPh$. [105°]. Formed by heating $CH_2Cl.CH:NPh$ with aniline (Berlinerblau, *M.* 8, 187). Sol. alcohol and ether.

PHENYL VINYL KETONE CARBOXYLIC ACID *v.* Benzoyl-acrylic acid.

DI-PHENYL-VINYL NITRITE $C_{14}H_{11}NO_2$ *i.e.* $CPh_2:CH.NO_2$. [87°]. Formed by gradually adding HNO_3 (1 pt.) to a hot solution of di-phenyl-ethane (1 pt.) in HOAc (10 pts.) (Anschütz a. Romig, *A.* 233, 327). Needles, v. sol. alcohol and ether.

? **TRI-PHENYL VINYL TRISULPHONE** $C_6H_5.SO_2.CH_2.CH(SO_2C_6H_5)_2$. [86°]. Formed by oxidising the product of the action of NaSPh on $CHCl_2.CH_2Cl$ (Otto, *B.* 24, 1835). Crystalline.

PHENYL-XYLENE *v.* Di-methyl-diphenyl and Phenyl-tolyl-methane.

PHENYL-XYLIDINE $C_{14}H_{15}N$ *i.e.* $C_6H_3Me_2.NHPh$. [52°]. (173° at 15 mm.). Formed by heating xylidine with aniline hydrochloride (Girard a. Vogt, *Bl.* [2] 18, 67). Sol. alcohol.

PHENYL-*o*-XYLYL-CARBINOL $C_{15}H_{16}O$ *i.e.* $C_6H_5.CH(OH).C_6H_3Me_2$ [1:3:4]? [68°]. (336° i.V.) at 744 mm. V.D. 107·7 (for 106). Formed from the ketone, KOH, and zinc-dust (Elbs, *J. pr.* [2] 35, 469). White radiating needles (from alcohol). Somewhat decomposed by distillation.

Phenyl-*m*-xylyl-carbinol $C_6H_5.CH(OH).C_6H_3Me_2$ [1:2:4]? [57°]. (331° i.V.) at 744 mm. V.D. 102·7 (for 106). Formed from the corresponding ketone by reduction (Elbs, *J. pr.* [2] 35, 472).

Phenyl-*p*-xylyl-carbinol $C_6H_5.CH(OH).C_6H_3Me_2$ [1:2:5]. [88°]. Formed from the ketone, KOH, and zinc-dust (Elbs). Prisms (from alcohol); v. sl. sol. water, m. sol. HOAc, v. e. sol. alcohol and ether.

PHENYL-*p*-XYLYL-*p*-CYMYL-METHANE [2:5:1]$Me_2C_6H_3.CHPh.C_6H_3MePr$[1:2:5]. Formed from phenyl-*p*-cymyl-carbinol, *p*-xylene, and P_2O_5 (Elbs, *J. pr.* [2] 35, 498). Oil.

DI-PHENYL-*o*-XYLYLENE-DIAMINE $C_{20}H_{20}N_2$ *i.e.* $C_6H_4(CH_2.NHPh)_2$. [172°]. Formed by boiling di-ω-bromo-*o*-xylene with an alcoholic solution of aniline (Lesser, *B.* 17, 1825). Small plates (from alcohol).

PHENYL *o*-XYLYL KETONE $C_{15}H_{14}O$ *i.e.* $C_6H_5.CO.C_6H_3Me_2$ [1:3:4]? [48°]. (340° i.V.) at 744 mm. V.D. 102·2 (for 105). Formed from BzCl, *o*-xylene, and $AlCl_3$; the yield is 80 p.c. (Elbs, *J. pr.* [2] 35, 467). Groups of snowy needles (from alcohol). Insol. water, sl. sol. cold HOAc, v. sol. alcohol.

Phenyl *m*-xylyl ketone $C_6H_5.CO.C_6H_3Me_2$ [1:2:4]. (321° i.V.) at 744 mm. V.D. 102·3 (for 105). From *m*-xylene, BzCl, and $AlCl_3$ (Söllscher, *B.* 15, 1682; Elbs, *J. pr.* [2] 35, 469). Oil. Partly converted by long boiling into (*B.* 2)-methyl-anthraquinone. In presence of a little of the corresponding phenyl-xylyl-carbinol, (*B.* 2)-methyl-anthracene is formed.

anti-Oxim $\begin{matrix}C_8H_9.C.C_6H_5\\ N.OH\end{matrix}$. [126°]. Converted by PCl_5 into $C_8H_9.CO.NHPh$ (Smith, *B.* 24, 4048). Yields an acetyl derivative [91°], crystallising in flat prisms.

syn-Oxim $\begin{matrix}C_8H_9.C.C_6H_5\\ HO.N\end{matrix}$. [152°]. Formed, as well as the preceding body, by the action of an alcoholic solution of hydroxylamine on the ketone. PCl_5 at −20° forms $C_6H_5.CO.NHC_8H_9$. Yields an acetyl derivative [103°].

Phenyl-*p*-xylyl ketone $C_6H_5.CO.C_6H_3Me_2$ [1:2:5]. [36°]. (317° i.V.) at 744 mm. V.D. 106·2 (for 105). From *p*-xylene, $AlCl_3$, and BzCl (Elbs, *B.* 17, 2847; *J. pr.* [2] 35, 472); the yield is 65 p.c. Transparent prisms (from alcohol), insol. water, m. sol. HOAc, v. e. sol. ether and alcohol. Very slightly volatile with steam. Yields methyl-anthracene when boiled for a long time.

Reaction.—1. H_2SO_4 has no action in the cold, but on warming HOBz is split off.—2. $H_2S_2O_7$ forms a disulphonic acid $C_6H_2Me_2.CO.C_6H_3(SO_3H)_2$, whose salt BaA″2aq is v. e. sol. water.—3. HNO_3 (S.G. 1·15) at 180° forms benzophenone dicarboxylic acid $C_6H_5.CO.C_6H_3(CO_2H)_2$ [1:2:5].

PHENYL-*o*-XYLYL-KETONE *o*-CARBOXYLIC ACID [4:3:1] $C_6H_3Me_2.CO.C_6H_4.CO_2H$ [2:1]. *Xylene-phthaloylic acid.* [162°]. Formed by the action of $AlCl_3$ on a mixture of phthalic anhydride and *o*-xylene (F. Meyer, *B.* 15, 636). Minute prisms (containing aq). Yields benzoic and (4,3,1)-di-methyl-benzoic acids when fused with potash.

Phenyl-*m*-xylyl-ketone *o*-carboxylic acid [4:2:1] $C_6H_3Me_2.CO.C_6H_4.CO_2H$. Formed in like manner from *m*-xylene (M.). Needles, sl. sol. water, sol. alcohol.

Phenyl-*p*-xylyl-ketone *o*-carboxylic acid [5:2:1] $C_6H_3Me_2.CO.C_6H_4.CO_2H$ [1:2]. Formed in like manner from *p*-xylene. Amorphous solid, insol. water, sol. alcohol and benzene.

Phenyl-*m*-xylyl-ketone (α)-carboxylic acid $C_6H_5.CO.C_6H_2Me_2.CO_2H$ [4:5:3:1]. [160°]. Formed, together with the following isomeride, by oxidising benzoyl-mesitylene with chromic acid mixture (Louise, *Bl.* [2] 44, 418; *A. Ch.* [6] 6, 218). Needles, v. sol. ether, insol. cold water.—BaA'_2 2aq.—MgA'_2 6aq.—AgA′: needles.

Phenyl-*m*-xylyl-ketone (β)-carboxylic acid $C_6H_5.CO.C_6H_2Me_2.CO_2H$[2:5:3:1]. [185°]. Formed as above. The Mg salt is more soluble than that of the isomeric acid. Efflorescent needles, v. sl. sol. hot water. Converted by P_2O_5 into di-methyl-anthraquinone [158°].—AgA′: needles.

Phenyl-xylyl-ketone dicarboxylic acid $C_6H_5.CO.C_6HMe_2(CO_2H)_2$. *Benzoyl-cumidic acid.* [85°]. Formed by oxidation of phenyl duryl ketone (F. Meyer a. Ador, *J.* 1879, 562). Melts at 85°, becomes solid, and melts again at 173°.—$BaA'_2 2\frac{1}{2}aq$: long silky needles.

PHENYL-DI-*p*-XYLYL-METHANE $C_6H_5.CH(C_6H_3Me_2)_2$ $[1:2:5]_2$. [93°]. (above 360°). From phenyl *p*-xylyl carbinol and *p*-xylene (Elbs, *J. pr.* [2] 35, 476). Or from di-*p*-xylyl carbinol, benzene, and P_2O_5. Prisms (from ligroïn). Its solutions show blue fluorescence.

Di-phenyl-*o*-xylyl-methane $C_{21}H_{20}$ *i.e.* $(C_6H_5)_2CH.C_6H_3Me_2$[1:3:4]. [68·5°]. (above 360°). Formed from di-phenyl-carbinol, *o*-xylene, and P_2O_5 (Hemilian, *B.* 19, 3070). Needles, v. sol. alcohol and ether.

Di-phenyl-*m*-xylyl-methane $(C_6H_5)_2CH.C_6H_3Me_2$ [1:2:4]. [61·5°]. (above 360°). Formed by boiling di-phenyl-carbinol with *m*-xylene and P_2O_5 (Hemilian, *B.* 19, 3061). Prisms, v. sol. alcohol and ether. Oxidised by chromic acid mixture to methyl-di-phenyl-phthalide and di-phenyl-phthalide carboxylic acid.

Di-phenyl-*p*-xylyl-methane. [92°]. (above 360°). Formed by digesting di-phenyl-carbinol with *p*-xylene and P_2O_5 (Hemilian, *B.* 16, 2360; *Bl.* [2] 34, 326; Petrieff, *Bl.* [2] 41, 316). Monoclinic crystals, v. sol. alcohol and ether. Oxidised by chromic acid mixture to di-phenyl-methyl-phthalide [179°], di-phenyl-tolyl-carbinol *m*-carboxylic acid [c. 253°] and di-phenyl-phthalide carboxylic acid [245°].

Reference.—NITRO-DI-AMIDO-PHENYL-DI-XYLYL-METHANE.

PHENYL-DI-XYLYL-METHANE *o*-CARBOXYLIC ACID [4:2:1] $C_6H_3Me_2.CH_2.C_6H_4.CO_2H$. [158°]. Formed by reducing phenyl-*m*-xylyl-ketone carboxylic acid with zinc-dust and NH_3Aq (Gresly, *A.* 234, 237). Small needles (from alcohol).—BaA'_2aq: plates (from dilute alcohol).

PHENYL-*p*-XYLYL-(β)-PINACOLIN $C_{30}H_{28}O$ *i.e.* $C_6H_5.C(C_6H_3Me_2)_2.CO.C_6H_5$. [146°]. Formed by the action of zinc and HClAq on phenyl *p*-xylyl ketone (Elbs, *J. pr.* [2] 35, 477). Clumps of prisms (from ligroïn), m. sol. alcohol and ether. Soda-lime at 320° splits it up into benzoic acid and phenyl-di-xylyl-methane.

PHENYL-XYLYL-PROPANE $C_{17}H_{20}$ *i.e.* $C_6H_5.CHMe.CH_2.C_6H_3Me_2$. (324°). Formed from ψ-cumene, styrene, and conc. H_2SO_4 (Kraemer, Spilker a. Ebenhardt, *A.* 23, 3273).

PHENYL-XYLYL-PROPIONIC ACID $C_6H_3Me_2.CHPh.CH_2.CO_2H$. Formed from cinnamic acid, *m*-xylene, and H_2SO_4 (Liebermann a. Hartmann, *B.* 25, 959). Amorphous, v. sol. warm benzene. When allocinnamic acid is used it is accompanied by another acid [220°].

DI-PHENYL-XYLYL-PYRROLE CARBOXYLIC ACID $C_8H_9N{<}\begin{smallmatrix}CPh:C.CO_2H\\ CPh:CH\end{smallmatrix}$. [254°]. Formed by saponifying its oily ether, which is got from phenacyl-benzoyl-acetic ether and (4,2,1)-*m*-xylidine (Paal a. Braikoff, *B.* 22, 3090). Small needles, m. sol. hot alcohol and benzene.

PHENYL-XYLYL SULPHONE $C_{14}H_{14}SO_2$, *i.e.* $C_6H_5.SO_2.C_6H_3Me_2$. [80°]. Formed from benzene sulphonic chloride, *m*-xylene, and $AlCl_3$ (Beckurts a. Otto, *B.* 11, 2069). Yellowish needles.

PHENYL *m*-XYLYL-UREA $C_{15}H_{16}N_2O$ *i.e.* $C_8H_9NH.CO.NHPh$. [131°]. Formed by mixing *m*-xylidine with phenyl cyanate (Brömme, *B.* 21, 2703). White matted needles, sol. alcohol.

PHENYTHRONIC ACID *v.* PHENYL-METHYL-FURFURANE DICARBOXYLIC ACID.

PHILLYRIN $C_{27}H_{34}O_{11}$ 1½aq. [160°]. S. ·08 at 9°; S. (alcohol) 2·5 at 9°. A glucoside in the bark of *Phillyrea latifolia* (Bertagnini, *A.* 92, 109; 118, 124). Crystalline, insol. ether. Split up by dilute acids into glucose and crystalline phillygenin $C_{21}H_{24}O_6$, v. sol. ether. A glucoside $C_{26}H_{32}O_{11}$ ([184°]; S. ·05 in the cold, 12·5 at 100°) in *Olea fragrans* is perhaps identical with phillyrin. It is split up by acids into glucose and $C_{20}H_{22}O_6$ [70°] (Eykman, *R. T. C.* 5, 127).

PHLEIN $C_{36}H_{62}O_{31}$. [215°]. S.G. 1·48. S. 3·26 at 10°. $[\alpha]_D = -48·5$. Occurs in the bulbs of cat's-tail grass (*Phleum pratense*) and in the roots of *Baldigera arundinacea* (Ekstrand a. Johanson, *B.* 20, 3310; 21, 597). Carbohydrate resembling starch, but not coloured blue by iodine. Reduces $AgNO_3$, but not Fehling's solution.

PHLOBAPHENE $C_{38}H_{20}O_{17}$. Named from φλοιός, bark, and βαφή, colour. Occurs in oak bark, and formed by boiling quercitannic acid with dilute acids (Hofstetter, *A.* 51, 63; Grabowski, *A.* 145, 8; Oser, *J.* 1876, 903; Böttinger, *A.* 202, 270; 240, 338). Reddish-brown powder, insol. water, ether, and cold alcohol. Alkalis form a reddish-brown solution, which absorbs oxygen from the air. Turned black by $FeCl_3$. Potash-fusion yields protocatechuic acid (Procter, *C. J.* 36, 979). Yields $C_{38}H_{19}Ac_7O_{17}$, $C_{38}H_{19}Bz_7O_{17}$, and $C_{38}H_{20}K_6O_{17}$, which is insol. alcohol, v. sol. water. Bromine yields $C_{38}H_{16}Br_{10}O_{17}$ and $C_{38}H_{20}Br_6O_{17}$, which forms $C_{38}H_{13}Br_6Ac_7O_{17}$. A substance $C_{50}H_{46}O_{25}$ resembling phlobaphene occurs in hops (Etti, *A.* 180, 223; *D. P. J.* 228, 354).

PHLOGISTIC THEORY *v.* COMBUSTION, vol. ii. pp. 241–2.

PHLORAMINE $C_6H_7NO_2$, *i.e.* $C_6H_3(OH)_2(NH_2)$. *Amido-resorcin?* Formed by passing NH_3 over phloroglucin (Hlasiwetz a. Pfaundler, *A.* 119, 202). Thin plates (from water), sl. sol. cold water, v. sol. alcohol, insol. ether. Turns brown in air. Decomposed by alkalis. Its solutions are not coloured by $FeCl_3$. —B'HCl.— $B'_2H_2SO_4$ 2aq: long yellowish needles.

PHLOREÏN $C_{18}H_{11}NO_7$. Formed by passing nitrous acid gas into an ethereal solution of phloroglucin (4 g.) containing HNO_3 (4 c.c. of S.G. 1·25) (Benedikt, *B.* 7, 445; *A.* 178, 93). Lustrous dark-green powder, insol. water, v. sol. alcohol and ether, forming a dark-brown solution. Alkalis form a purple solution. Yields phloroglucin when fused with potash. Zinc and dilute H_2SO_4 form a colourless body, re-oxidised to phloreïn by air.

PHLORETIC ACID *v.* *p*-OXY-α-PHENYL-PROPIONIC ACID. It yields a crystalline di-bromo-derivative (Hlasiwetz, *A.* 102, 145).

PHLORETIN $C_{15}H_{14}O_5$. [255°]. Formed by boiling phlorizin or glycyphyllin with dilute acids (Stas, *A.* 30, 200; G. Roser, *A.* 74, 178; Hlasiwetz, *A.* 96, 118; Schiff, *A.* 156, 2; 172, 357; 229, 374; Rennie, *C. J.* 49, 860). Small laminæ, with sweet taste, v. sl. sol. hot water and ether, v. e. sol. alcohol. Inactive to light. Bromine forms $C_{15}H_{10}Br_4O_5$ [205°–210°] (Schmidt a. Hesse, *A.* 119, 103). Alkaline solutions absorb oxygen and turn orange in air; boiling conc. KOHAq splits it up into phloretic acid and phloroglucin. Aniline at 170° forms $C_{21}H_{19}NO_4$, a scarlet powder. AcCl gives amorphous $C_{15}H_{12}Ac_2O_5$ aq.

Salts.—$C_{15}H_{11}(NH_4)_3O_5$: amorphous. Gives off NH_3 in air.—$C_{30}H_{18}Pb_5O_{10}$ 5aq.—$C_{15}H_{13}AgO_5$: unstable pp.

PHLORIZIN $C_{21}H_{24}O_{10}$ 2aq. Named from φλοιός, bark, and ῥίζα, root. [109°] (when anhydrous). S.G. ^{19} 1·43. S. ·1 in the cold. $[\alpha]_D = -49$ at 15°. Occurs in the root-bark of the apple, pear, plum, and cherry tree, from which it may be extracted by dilute alcohol (Stas a. De Koninck, *A.* 15, 75; 30, 193; *A. Ch.* [2] 69, 367; Mulder, *Rev. Scient.* 3, 50; Roser, *A.* 74, 178; Strecker, *A.* 74, 184; Rennie, *C. J.* 51, 635). Silky needles with slightly bitter taste, sl. sol. cold water, v. e. sol. hot water and alcohol, insol. ether. Melts at 109°, becomes solid, and melts again at 171°. Lævogyrate. Decomposed by dilute acids into glucose and phloretin. Gives pps. with baryta and MeOH, with lime-water, and with lead subacetate. Air and ammonia form reddish-brown amorphous phlorizeïn $C_{21}H_{30}N_2O_{13}$. Gives a violet colour on boiling with $ZnSO_4$ and KNO_2 (Nickel, *Fr.* 28, 248). $FeCl_3$ gives a brownish-red colour. Aniline at 180° forms $C_{33}H_{34}N_2O_8$, a yellow powder, yielding a mono- and a tri- acetyl derivative.

Acetyl derivatives $C_{21}H_{23}AcO_{10}$ 2aq: needles (from water). — $C_{21}H_{21}Ac_3O_{10}$. — $C_{21}H_{19}Ac_5O_{10}$ aq: amorphous solid.

Tri-benzoyl derivative. Powder.

Isophlorizin $C_{21}H_{24}O_{10}$. [105°]. Occurs in the leaves of the apple-tree (Rochleder, *Z.* [2] 4, 741). Silvery needles. Its ammoniacal solution turns brown in air. Its solution is ppd. by lead subacetate. Dilute H_2SO_4 splits it up into glucose and isophloretin $C_{15}H_{14}O_5$, which is v. sol. ether, and yields phloroglucin when heated with conc. KOHAq.

PHLOROBROMIN C_6Br_5HO. [152°]. Formed by the action of excess of bromine on a very dilute aqueous solution of phloroglucin (Benedikt, *A.* 189, 165; *C. J.* 34, 499). Dimetric prisms; $a:b = 1:1·2$. Insol. water. Not attacked by potash or HNO_3. Warm alcohol decomposes it, forming penta-bromo-acetone [76°]. NH_3Aq forms CBr_3H and $C_5Br_6H_4N_2$, crystallising from water in colourless laminæ [124°].

PHLOROGLUCIN $C_6H_6O_3$ *i.e.* $C_6H_3(OH)_3$ [1:3:5]. Mol. w. 126. [219°] (Baeyer, *B.* 19, 2186). H.F. 153,348 (Stohmann, *J. pr.* [2] 33, 471).

Formation.—1. By boiling phloretin with conc. KOHAq (Hlasiwetz, *A.* 96, 118).—2. By potash-fusion from quercetin, maclurin, catechin, scoparin, gamboge, dragon's blood, limettin, and bergaptene (Hlasiwetz, *A.* 112, 96; 119, 199; 127, 357; 134, 118, 283; 138, 190; Zwenger, *A.* 123, 154; Gautier, *Bl.* [2] 33, 583; Tilden a. Beck, *C. J.* 57, 323; Pomeranz, *M.* 12, 387).—3. By fusing resorcin with a large excess of NaOH, the yield being 65 p.c. (Barth a. Schreder, *B.* 12, 503).—4. By soda-fusion from phenol, benzene, trisulphonic acid, orcin, and naringenin (Barth a. Schreder, *B.* 12, 422; *M.* 3, 649; Will, *B.* 20, 297).—5. By fusing its tricarboxylic ether with potash (Baeyer, *B.* 19, 3458).—6. By fusing *s*-di-bromo-phenol with potash (Blau, *M.* 7, 632).

Preparation.—By soda-fusion from resorcin (Tiemann a. Will, *B.* 14, 954; 18, 1323).

Properties.—Trimetric crystals (containing 2aq); $a:b:c = ·825:1:3·417$. Melts at 200°-209° when slowly heated. V. sol. water, alcohol, and ether; sl. sol. NaClAq. Tastes sweeter than sugar. May be sublimed. Its solution is ppd. by lead subacetate. $FeCl_3$ gives a bluish-violet colour. Reduces Fehling's solution and ammoniacal $AgNO_3$. Its alkaline solution absorbs oxygen and turns brown in air. Colours acidified pine-wood red. An alcoholic solution gives a red colour with HClAq and vanillin (Lindt, *Fr.* 26, 260), oil of cloves, or oil of pimento (Ihl, *Chem. Zeit.* 13, 204).

Reactions.—1. *Bromine* forms crystalline tri-bromo-phloroglucin and finally phlorobromin. 2. *Chlorine* passed into its aqueous solution forms tri-chloro-phloroglucin $C_6Cl_3(OH)_3 3aq$ [136°], which soon decomposes into tetra-chloro-acetone hydrate, and di-chloro-acetic acid (Webster, *C. J.* 47, 423; Zincke a. Kegel, *B.* 22, 1476). Chlorine passed into its solution in HOAc forms $CHCl_2.CO.CHCl_2 4aq$ [49°]. Chlorine passed into a cooled solution of dry phloroglucin in chloroform forms $CO\Big\langle\begin{smallmatrix}CCl_2.CO\\CCl_2.CO\end{smallmatrix}\Big\rangle CCl_2$ [48°], (269°), decomposed by water into CO_2, di-chloro-acetic acid, and $CO(CHCl_2)_2$.—3. Dilute HNO_3 forms nitro-phloroglucin.—4. *Ammonia* produces phloramine.—5. *Nitrous acid* in its ethereal solution forms phloreïn. In acetic acid solution it gives tri-nitroso-phloroglucin (vol. iii. p. 619).—6. Aqueous HI at 140° forms nearly tasteless scales of phloroglucide $C_{12}H_{10}O_5 2aq$, sl. sol. warm water. Phloroglucide is also got by heating phloroglucin alone or with $POCl_3$.—7. Heated with *salicylic acid* it forms two compounds of the form $C_6H_4\Big\langle\begin{smallmatrix}O\\CO\end{smallmatrix}\Big\rangle C_6H(OH)\Big\langle\begin{smallmatrix}O\\CO\end{smallmatrix}\Big\rangle C_6H_4$, one of these (described by Kostanecki and Nessler) which yields an acetyl derivative $C_{20}H_9O_4(OAc)$ [218°]; the other isomeride [326°] crystallises from HOAc in green-yellow tables.—8. With *o-amido-benzoic aldehyde* and NaOHAq it forms red $C_{13}H_9NO_3$, possibly di-oxy-acridine $C_6H_2(OH)_2\Big\langle\begin{smallmatrix}N\\CH\end{smallmatrix}\Big\rangle C_6H_4$, which forms $B'_2H_2PtCl_6$ and $C_{13}H_7Bz_2NO_3$ (Eliasberg a. Friedländer, *B.* 25, 1752).—9. *Phenyl cyanate* unites, forming $C_6H_3(O.CO.NHPh)_3$, a yellowish powder [128°] (Goldschmidt a. Meissler, *B.* 23, 269).—10. *Benzene sulphonic chloride* added to the slightly alkaline solution forms $C_6H_3(O.SO_2C_6H_5)_3$ [117°] (Georgesen, *B.* 24, 418).—11. *Aniline* at 210° forms tri-phenyl-tri-amido-benzene [193°] (Minunni, *B.* 21, 1984).—12. *Phloretic acid* at 170° forms $C_{33}H_{28}O_{14}$, crystallising from water in laminæ (Hlasiwetz, *A.* 119, 199).

Tri-oxim $C_6H_6(NOH)_3$. Formed from phloroglucin and aqueous hydroxylamine (Baeyer, *B.* 19, 159). Colourless crystals, v. sl. sol. water and alcohol, sol. alkalis and acids. Explodes at 155°.

Phenyl-hydrazine derivatives. The salt $C_6H_6O_3N_2H_3Ph$ [78°-83°] is got from phloroglucin (1 mol.) and phenyl-hydrazine (3 mols.) in alcoholic solution (Baeyer a. Kochendörfer, *B.* 22, 2190). Nodules, sol. alcohol and ether. Cold NaOHAq sets free phenyl-hydrazine. In alcoholic solution it changes on keeping to $C_6H_3(OH)(N_2H_2Ph)_2$ [144°], which crystallises from toluene in needles, and yields a penta-benzoyl derivative [176°].

Tri-acetyl derivative $C_6H_3(OAc)_3$. [106°]. Got by heating phloroglucin with AcCl.

Di-benzoyl derivatives $C_6H_3(OH)(OBz)_2$. Two isomerides [165°] and [191°-195°] are got from phloroglucin with BzCl. The compound [165°] is more sol. benzene than the other (Skraup, *M.* 10, 391, 722).

Tri-benzoyl derivative $C_6H_3(OBz)_3$. [174°]. Formed, together with $C_{12}H_6(OBz)_4$ [199°], by warming phloroglucin with BzCl and NaOH (S.). Plates, sol. benzene.

Tri-methyl ether $C_6H_3(OMe)_3$. [52°]. (256°). Formed by passing HCl into a solution of phloroglucin in MeOH, the resulting $C_6H_3(OH)(OMe)_2$ being treated with MeI and KOH (Will, *B.* 21, 603). Crystals, insol. water and alkalis, v. sol. alcohol and ether. Conc. HNO_3 forms a blue solution. Bromine gives $C_6Br_3(OMe)_3$ [145°]. When phloroglucin is treated with KOH and MeI the products are $C_6H_3Me_3O_3$ [184°], $C_6H_2Me_4O_3$ [114°], and $C_6Me_6O_3$ [80°] (Margulies, *M.* 9, 1052; 10, 459). When tetra-methyl-phloroglucin is heated in sealed tubes with HClAq it yields isopropyl ketone, isobutyric acid, HOAc, and CO_2. Hence it would appear to be $CMe_2\Big\langle\begin{smallmatrix}CO.CH\\CO.CMe_2\end{smallmatrix}\Big\rangle C.OH$ (Spitzer, *M.* 11, 104, 287). Hexamethyl-phloroglucin heated with HIAq at 200° produces isobutyric acid and C_7H_{14}, and, on oxidation, yields di-isopropyl ketone. Hence it would appear to be $CMe_2\Big\langle\begin{smallmatrix}CO.CMe_2\\CO.CMe_2\end{smallmatrix}\Big\rangle CO$.

Di-ethyl ether $C_6H_3(OEt)_2(OH)$. [[illegible]°]. Made by passing HCl into an alcoholic solution of phloroglucin or its carboxylic acid (Will a. Albrecht, *B.* 17, 2106). Long white needles. May be distilled.

Tri-ethyl ether $C_6H_3(OEt)_3$. [43°]. Got by heating the di-ethyl ether with EtI and alcoholic potash (W. a. A.).

Penta-ethyl derivative *v.* vol. ii. p. 505.

Tri-phenyl ether $C_6H_3(OPh)_3$? [175°]. A product of the action of Na on phenyl acetate (Hodgkinson, *C. J. Proc.* **2**, 188). V. sl. sol. Aq.

References.—TRI-BROMO-, BROMO-DI-IODO-, TRI-CHLORO-, NITROSO-, and NITRO- PHLOROGLUCIN.

PHLOROGLUCIN CARBOXYLIC ACID *v.* TRI-OXY-BENZOIC ACID.

Phloroglucin tricarboxylic ether $C_{15}H_{18}O_9$ *i.e.* $C_6(OH)_3(CO_2Et)_3$. [106°]. Formed from malonic ether and $ZnEt_2$ (Lang, *B.* 19, 2937). Prepared by dissolving Na (14·4 g.) in malonic ether (200 g.) at 100° and heating the product for six hours at 145° (Baeyer, *B.* 18, 3457; Bally, *B.* 21, 1766). In this preparation an anhydride $C_6(OH)_2(CO_2Et)_2{<}\begin{smallmatrix}O\\CO\end{smallmatrix}$ [170°] is also formed. Needles (from dilute alcohol), insol. water. Does not react with nitrous acid gas.

Reactions.—1. *Potash-fusion* yields phloroglucin.—2. *Bromine* in CS_2 ppts. bromo-phloroglucin dicarboxylic ether [128°].—3. *Chlorine* gives tri-chloro-acetamide.—4. *Phenyl cyanate* and C_6H_6 at 200° form $C_6(O.CO.NHPh)_3(CO_2Et)_3$ [195°] (Goldschmidt a. Meissler, *B.* 23, 270).

Tri-acetyl derivative $C_6(OAc)_3(CO_2Et)_3$. [76°]. Needles (from alcohol or ether).

Oxim $C_6H_3(NOH)_3(CO_2Et)_3$. [171°].

PHLOROGLUCIN-PHTHALEÏN $C_{20}H_{12}O_7$. Formed by heating phloroglucin with phthalic anhydride at 170° (Link, *B.* 13, 1652). Minute orange needles, sl. sol. water. Its alkaline solutions are orange-red, without fluorescence. Zinc-dust and NaOHAq reduce it to phloroglucin-phthalin $C_{20}H_{14}O_7$, an amorphous reddish-yellow mass.

PHLOROGLUCIN SULPHONIC ACID $C_6H_6SO_6$ *i.e.* $C_6H_2(OH)_3.SO_3H$. Formed by mixing phloroglucin with $H_2S_2O_7$ (Schiff, *B.* 6, 26; *A.* 178, 191). Yields a crystalline K salt. $POCl_3$ converts it into the anhydrides $C_{12}H_{10}S_2O_{11}$, v. e. sol. water, and $C_{12}H_8S_2O_{10}$, sl. sol. water, and $C_{24}H_{16}S_2O_{15}$.

PHLOROL *v.* *o*-ETHYL-PHENOL.

PHLORONE *v.* XYLOQUINONE.

PHORONE $C_9H_{14}O$ *i.e.* $CO(CH:CMe_2)_2$. Mol. w. 138. [28°]. (197°) at 743 mm. S.G. $\frac{20}{4}$ ·885. $\mu_D = 1{\cdot}500$ at 20° (Brühl, *A.* 235, 15). R_∞ 70·93 in a 14·5 p.c. benzene solution. Formed, together with mesityl oxide, by leaving acetone in contact with quicklime (Fittig, *A.* 110, 32). Formed also by the action of conc. HClAq on acetone (Baeyer, *A.* 140, 301), and by heating nitroso-triacetonamine with potash (Heintz, *A.* 187, 250). Yellowish prisms. Yields acetone, oxalic acid, and CO_2 on oxidation with $KMnO_4$ (Pinner, *B.* 15, 591). Slowly combines with $NaHSO_3$, forming di-isobutyl ketone di-sulphonic acid. Yields ψ-cumene on heating with P_2O_5 and mesitylene on heating with conc. H_2SO_4. Yields mesityl oxide on distilling with dilute H_2SO_4 (Claisen, *A.* 180, 18). Bromine in CS_2 forms $C_9H_{14}Br_4O$ [88°]. Zinc and H_2SO_4 reduce it, in alcoholic solution, to deoxyphorone $C_{18}H_{28}O$ [108°]. HI forms $C_9H_{16}I_2O$ [13°] (Kasaneff, *B.* 8, 435). Phorone does not react with benzoic aldehyde (Claisen, *B.* 14, 352).

Oxim C_9H_{14}:NOH. [48°]. (218°). Tables, v. sol. alcohol (Nägeli, *B.* 16, 496).

Isophorone. The substance to which this name has been given is a mixture (Laycock, *A.* 258, 230).

Camphor-phorone $C_9H_{14}O$ *i.e.*

$$CMe{<}\begin{matrix}CH_2.CH_2\\ \hline CO\end{matrix}{>}CPr$$

(Königs a. Eppens, *B.* 25, 260). (208°) (Kachler, *A.* 164, 79). Got by distilling calcium camphorate (Laurent, *A. Ch.* [2] 65, 329; Gerhardt a. Liès-Bodart, *A.* 72, 293) and by heating camphor (1 pt.) with H_2SO_4 (4 pts.) at 100° (Schwanert, *A.* 123, 298). Colourless oil with aromatic odour. Inactive to light. PCl_5 yields $C_9H_{13}Cl$ (205°). Yields α-methyl-glutaric and acetic acids on oxidation. Na followed by MeI yields $C_9H_{13}MeO$ (225°–230°). Na followed by AcCl yields $C_{18}H_{27}AcO_2$ (230°–240°). Bromine in CS_2 forms $C_9H_{13}Br_3O$ [52°].

PHORONIC ACID $C_{11}H_{18}O_5$. [184°]. Formed by saponification of its nitrile, which is got by boiling the product of the action of gaseous HCl on acetone with alcoholic potash (Pinner, *B.* 14, 1071; 15, 585). Large prisms (from dilute alcohol), sl. sol. water.—KHA″ 1½aq: needles, v. sol. water.—CaA″ 3aq: prisms.—Ag_2A'' aq: pp.

Ethyl ether Et_2A''. [125°].

Amide. [above 300°]. Prisms.

Anhydride $C_{11}H_{16}O_4$. [138°]. Got by heating the acid at 190°.

Imide $C_{11}H_{16}O_3(NH)$. [205°]. Formed from the anhydride and alcoholic NH_3.

Nitrile $C_{11}H_{18}N_2O_2$. [above 320°].

PHOSENE *v.* SYNANTHRENE.

PHOSGENE GAS. Another name for $COCl_2$; *v.* CARBON OXYCHLORIDE, vol. i. p. 692.

PHOSPHAM. (?)PN_2H. When dry NH_3 is passed into well-cooled PCl_3, a solid colourless mass is obtained, said by H. Rose to contain PCl_3 and NH_3 in the ratio PCl_3:$5NH_3$ (*P.* 24, 308; 28, 529). This substance is probably a mixture of various compounds; other substances are formed if the PCl_3 is not cooled. If PCl_5 is treated with NH_3 at the ordinary temperature, $5NH_3$ are absorbed by PCl_5 (H. Rose, *l.c.*); from this product ether dissolves out $N_3P_3Cl_6$ (*v.* NITROGEN PHOSPHOCHLORIDE, vol. iii. p. 570); if the product is heated, HCl and NH_4Cl are evolved, and a white, loose powder remains, to which Gerhardt (*A. Ch.* [3] 18, 188; 20, 225) gave the composition PN_2H and the name *phospham*. Liebig a. Wöhler (*A.* 11, 139) obtained this compound by passing PCl_3 or PCl_5 over heated NH_4Cl, and washing and heating the product; they supposed it to be PN_2. The same substance was obtained by Pauli (*A.* 101, 41) by heating an intimate mixture of P_2S_5 and NH_4Cl, also by heating red P with S and NH_4Cl, and by heating powdered Ca phosphide with S and NH_4Cl, and washing the residue with an acid. Pauli's analyses showed less N than is required by the formula PN_2H. By treating PCl_5 with NH_3, washing for a long time with water, digesting with HClAq, then with KOHAq, washing with water and then with ether, Salzmann (*B.* 7, 494) obtained a substance resembling phospham and approximately agreeing with the composition $P_3N_5H_4$; Salzmann regarded this substance as probably a mixture of several very similar compounds of P, N, and H. Besson (*C. R.* 114, 1264) says that PCl_5 absorbs $8HN_3$, and that on heating PN_2H is formed.

Phospham is a white, loose powder; insoluble in ordinary solvents; melts and vaporises when heated in absence of air; oxidised by heating in air; yields HPO_3 and HN_3 when moistened with water and heated (Gerhardt, *l.c.*); fused with KOH or BaO_2H_2 forms NH_3 and orthophosphate, with incandescence.

Phospham may be regarded as one of the nitriles of H_3PO_4: thus $PO.OH.(ONH_4)_2 - 4H_2O = PN_2H$; the other nitriles would be PON, which is known (*v.* PHOSPHORUS OXYNITRIDE, p. 144) [$PO(OH)_2ONH_4 - 3H_2O = PON$], and PN_3H_4, which has not been isolated [$PO(ONH_4)_3 - 4H_2O = PN_3H_4$]. Mendelejeff (*B.* 23, 3472 *note*) thinks it likely that phospham is a polymeride of PN_2H, inasmuch as it is analogous to N_3H (*hydrazoic acid*, vol. iii. p. 559) and both P and P compounds show a greater readiness to polymerise than N and compounds of N. M. M. P. M.

PHOSPHAMIC ACIDS AND ALLIED COMPOUNDS. Two amic acids may be derived theoretically from $PO(OH)_3$, viz. $PONH_2(OH)_2$ and $PO(NH_2)_2OH$; both acids have been isolated. The compound $PO(NH_2)_3$ is described as PHOSPHAMIDE, and $PO.NH.NH_2$ as PHOSPHAMIDO-IMIDE (*infra*). The two thiophosphamic acids, $PS.NH_2.(OH)_2$ and $PS(NH_2)_2OH$ are probably formed by the action of NH_3 on $PSCl_3$ (*v.* THIOPHOSPHORYL CHLORIDE, *Reaction* 7, p. 148). The three amic acids (or salts of these) derivable from $H_4P_2O_7$ are known: $P_2O_3NH_2(OH)_3$, $P_2O_3(NH_2)_2(OH)_2$, and $P_2O_3(NH_2)_3OH$. By heating $P_2O_3(NH_2)_3OH$ the NH_4 salt of the acid $P_2O_3(OH)N$ is obtained. There are also several acids (or their salts) known, which may be derived from hypothetical $P_4O_7(OH)_6[2P_2O_3(OH)_4 - H_2O = P_4O_7(OH)_6]$ by replacing OH by NH_2 or NH. Imidophosphoric acid, PO.NH.OH, perhaps exists.

PHOSPHAMIC ACID $PO.NH_2(OH)_2$. (*Amidophosphoric acid.*) Obtained by Stokes (*Am.* 15, 198 [1893]) by suspending the lead salt in a little ice-water, decomposing by excess of H_2S, and filtering into alcohol. White microscopic crystals; easily sol. water; does not give NH_3 with caustic alkalis; heated to 100° is slowly changed to an NH_4 salt, perhaps $NH_4.PO_3$; aqueous solution soon changes to $NH_4H_2PO_4$. Acid and normal salts have been prepared. The lead salt is formed by adding lead acetate to a solution of $PO.NH_2.OH.OK$, which salt is produced by adding alcoholic NH_3 to an alcoholic solution of $PO.Cl(OPh)_2$, and saponifying the $PO.NH_2(OPh)_2$ thus formed by KOHAq.

PHOSPHODIAMIC ACID $PO.(NH_2)_2OH$. (*Diamidophosphoric acid.*) Stokes (*B.* 27, 565 [1894]) prepared this acid by saponifying the product of the action of NH_3Aq on $POCl_2(OPh)$. The acid gives salts $PO(NH_2)_2OM$, and also salts of an acid $P(NH_2)_2(OH)_3$ (*Abstract* in *C. J.* 66 [11], 188 [1894]).

PYROPHOSPHAMIC ACID $P_2O_3(NH_2)(OH)_3$. This is said by Gladstone (*C. J.* 17, 229) to be the chief product of the action of NH_3 on P_2O_5; Schiff (*A.* 103, 168) formulated this product as PO.NH.OH, *imido-phosphoric acid*; Stokes (*l.c.*) says the product is a mixture. For details *v.* G. (*l.c.*; also *C. J.* 3, 135; 21 64); also G. a. Helmes (*C. J.* 17, 225).

PYROPHOSPHODIAMIC ACID $P_2O_3(NH_2)_2(OH)_2$ (G., *C. J.* 19, 290; G. a. H., *l.c.*). Formed by action of water or alkalis on $N_3P_3Cl_6$, by treating $POCl_3$ with conc. NH_3Aq, and in many other ways. A white amorphous solid, easily soluble in water and alcohol. The acid is dibasic. The salts are difficult to obtain pure, as they easily change into pyrophosphamates; salts of Ba, Ag, and Zn are described.

PYROPHOSPHOTRIAMIC ACID $P_2O_3(NH_2)_3OH$ (G., *C. J.* 19, 1; 21, 64). Dry NH_3 is passed into $POCl_3$ until saturated, the product is heated to 220° and boiled for a short time with water, the residue is washed with cold water, and then with a little dilute alcohol. A white, amorphous, tasteless powder, nearly insoluble in water; slowly acted on by cold water, more quickly by hot water, yielding $P_2O_3(NH_2)_2(OH)_2Aq$ and NH_3Aq; boiled with HClAq gives H_3PO_4 and NH_3. *Pyrophosphotriamates* of NH_4, Ba, Cd, Co, Cu, Cr, Fe, Pb, Mg, Mn, Hg, Ni, Pt, K, Ag, Tl, and Zn are described; the acid is said to be tetrabasic.

PYROPHOSPHONITRILIC ACID $P_2O_3(OH)N$. The NH_4 salt of this acid is said to be formed by heating $P_2O_3(NH_2)_3OH$, and the K salt by heating $P_2O_3(NH_2)_3OK$ (G., *C. J.* 22, 19).

TETRAPHOSPHAMIC ACIDS AND ALLIED COMPOUNDS. By the reaction of NH_3 with $POCl_3$ under different conditions, Gladstone (*C. J.* 21, 261; 22, 15), obtained various compounds which may be regarded as (1) *tetraphosphodiamic acid* $P_4O_7(NH_2)_2(OH)_4$, (2) $P_4O_7(NH_2)_4(OH)_2$ *tetraphosphotetramic acid*, (3) ? *tetraphospho-imido-tetramide* $P_4O_7(NH_2)_4NH$ (called by G. *tetraphosphopentazotic acid*), (4) ? *tetraphosphodiimido-diamide* $P_4O_7(NH_2)_2(NH)_2$ (called by G. *tetraphosphotetrimic acid*). Some of the above acids are regarded by Mente (*A.* 248, 232) as imido-acids. M. M. P. M.

PHOSPHAMIDES. I. PHOSPHORIC TRIAMIDE $O.P(NH_2)_3$ (*Phosphoryl triamide*) [derived from $O.P(OH)_3 = H_3PO_4$]. This compound is said by Schiff (*A.* 101, 300) to be obtained by passing NH_3 gas into $POCl_3$, and treating the product with water. It is described as a snow-white, amorphous solid; heated out of air gives NH_3 and PON; fused with KOH gives NH_3 and K phosphate; scarcely acted on by boiling water, KOHAq, or dilute acids; soluble in hot conc. H_2SO_4; slowly attacked by boiling conc. HNO_3 or HClAq. Gladstone (*C. J.* 22, 18) could not obtain this compound.

II. PHOSPHOROUS DIAMIDE $OH.P.(NH_2)_2$ [derived from $OH.P(OH)_2 = H_3PO_3$]. The white powder produced by passing NH_3 into P_4O_6 in benzene or ether has probably this composition (Thorpe a. Tutton, *C. J.* 59, 1027). It dissolves in water with incandescence; HClAq reacts violently, forming non-inflammable PH_3, P, NH_4Cl, H_3PO_3Aq, and H_3PO_4Aq.

THIOPHOSPHAMIDE is described under THIOPHOSPHORYL CHLORIDE, *Reactions*, No. 7, p. 148.

M. M. P. M.

PHOSPHAMIDO-IMIDE $PO.NH.NH_2$ (*Phosphoryl imido-amide.* Formerly called *Phosphodiamide*) (Gerhardt, *A. Ch.* [3] 18, 188; Schiff, *A.* 101, 300). Obtained by saturating PCl_5 with NH_3, boiling the product with water as long as HCl passes into solution, then boiling with potash, then with HNO_3Aq or H_2SO_4Aq, washing, and drying over H_2SO_4. A white powder, insoluble in alcohol, water, or turpentine; heated out of air gives NH_3 and PON; heated in moist air gives NH_3 and HPO_3; fused with KOH gives K phosphate and NH_3; slowly oxidised by fusion with KNO_3, but resists action of most oxidisers. M. M. P. M.

PHOSPHATES. *Salts of the phosphoric acids.* Besides the salts directly derived from the three phosphoric acids HPO_3, H_3PO_4, and $H_4P_2O_7$ (*v.* PHOSPHORIC ACIDS, p. 124), phosphates exist which are probably derived from hypothetical di-, tri-, or meta- phosphoric acid $nHPO_3$; and a few salts have been isolated which are perhaps derived from the hypothetical acids $P_4O_7(OH)_6$ and $P_{10}O_{19}(OH)_{12}$.

Composition.—*Orthophosphates* are derived from H_3PO_4; they may be divided into classes according to the replacing powers of the metals: (1) monovalent metals form MH_2PO_4, M_2HPO_4, and M_3PO_4; (2) divalent metals form $MH_4P_2O_8$, $MHPO_4$, and $M_3P_2O_8$; (3) trivalent metals form $MH_3P_2O_8$ and $M_2P_2O_8$; (4) tetravalent metals form $MH_2P_2O_8$ and $M_3P_4O_{16}$.

Pyrophosphates are derived from $H_4P_2O_7$: (1) salts of monovalent metals $M_2H_2P_2O_7$ and $M_4P_2O_7$; (2) salts of divalent metals $MH_2P_2O_7$ and $M_2P_2O_7$, &c.

Metaphosphates are derived from HPO_3: (1) salts of monovalent metals MPO_3; (2) salts of divalent metals MP_2O_6, &c. Various modifications of Na (and other) metaphosphates are known, all having the empirical formula MPO_3, but differing both in physical and chemical properties from one another; these salts were classified by Fleitmann a. Hanneberg (*A.* 65, 304; F., *P.* 78, 233, 338) as: (1) *dimetaphosphates*, salts of $H_2P_2O_6$; (2) *trimetaphosphates*, salts of $H_3P_3O_9$; (3) *tetrametaphosphates*, salts of $H_4P_4O_{12}$; and (4) *hexametaphosphates*, salts of $H_6P_6O_{18}$. Tammann (*Z. P. C.* 6, 122) has examined the electrical conductivities, and the depressions of freezing-points, of aqueous solutions of several di-, tri-, and hexa- metaphosphates; he comes to the conclusion that Fleitmann's dimetaphosphates should be represented in solution as $M_3(PO_3)_3$ (*i.e.* as trimetaphosphates), and [illegible]is tri- salts when in solution are really $M_2(PO_3)_2$ (*i.e.* dimetaphosphates). Tammann's results point to the existence in aqueous solution of 3 isomeric hexametaphosphates which may be represented as (i.) $M_2.M_4(PO_3)_6$ *e.g.* $Na_2.Na_4(PO_3)_6$, $K_2.Na_4(PO_3)_6$; (ii.) $M_4.M_2(PO_3)_6$ *e.g.* $Na_4.Na_2(PO_3)_6$, $Ag_4.Na_2(PO_3)_6$; (iii.) $M_5.M(PO_3)_6$ *e.g.* $Na_5.Na(PO_3)_6$, $(NH_4)_5.Na(PO_3)_6$. There are also, according to Tammann, three different Na metaphosphates insoluble in water (*v.* also T., *J. pr.* [2] 45, 417).

Tetra-* and *deka-phosphates. Salts of the compositions $Na_6P_4O_{13}$ and $Na_{12}P_{10}O_{31}$ are obtained by fusing together $Na_4P_2O_7$ and $Na_6(PO_3)_6$; these salts may be regarded as derived from the hypothetical condensed acids $H_6P_4O_{13}$ ($=3H_4P_2O_7-H_2O$), and $H_{12}P_{10}O_{31}$ ($=5H_4P_2O_7-4H_2O$), respectively.

The composition of all the phosphates may be represented empirically by the expression $nMO.mP_2O_5.xH_2O$, where MO stands for a basic oxide.

Occurrence.—Phosphates of Al and Ca occur in large quantitie[illegible] rocks; phosphates of Fe, Pb, Mg, NH_4, &c. are also widely distributed minerals. Coprolites (the fossilised excrements of former land-animals), and guano (the excrement of certain birds) consist very largely of Ca phosphate. Phosphates occur in some kinds of coal, in the ashes of plants, and in the bones of animals.

Formation.—Some of the *orthophosphates* are obtained by reacting on H_3PO_4Aq with metallic oxides or carbonates; others are formed by double decomposition from the alkali phosphates; when a metaphosphate is fused with a metallic oxide or hydroxide a normal orthophosphate is generally formed. Many *pyrophosphates* are obtained by double decomposition from $Na_4P_2O_7$, which is formed by strongly heating Na_2HPO_4; other pyrophosphates are found by neutralising $H_4P_2O_7Aq$ by basic oxides or hydroxides. *Metaphosphates* are generally formed by strongly heating orthophosphates MH_2PO_4 or $MRHPO_4$, when M or R is a metal whose oxide is volatile; many are produced by double decomposition from $NaPO_3$; some are formed by heating $Cu_2(PO_3)_4$ with a metallic sulphide and filtering from CuS.

The processes by which any one of the three classes of phosphates is formed from another is perhaps best understood by representing the phosphates thus:

meta	*pyro*	*ortho*
$P_2O_5.M_2O$	$P_2O_5.2M_2O$	$P_2O_5.3M_2O$

Metaphosphate becomes pyro- by gaining M_2O, and becomes ortho- by gaining $2M_2O$, and so on. Metaphosphate fused with metallic oxide, hydroxide, or carbonate yields pyrophosphate or orthophosphate, according to the quantities used; thus (1) $2NaPO_3+Na_2CO_3=Na_4P_2O_7+CO_2$; (2) $2NaPO_3+2Na_2CO_3=2Na_3PO_4+2CO_2$. The metaphosphate of a heavy metal yields an orthophosphate and H_3PO_4 by boiling with water; thus $3AgPO_3+3H_2O=Ag_3PO_4+2H_3PO_4$. The change from a pyro- to an ortho- phosphate is often effected by boiling with water, the product being an acid salt, thus $Na_4P_2O_7+H_2O=2Na_2HPO_4$; or the pyrophosphate is fused with hydroxide or carbonate, thus

$$Ba_2P_2O_7+BaO_2H_2=Ba_3(PO_4)_2+H_2O.$$

Acid orthophosphates with one atom of H yield pyro-phosphates when strongly heated, *e.g.* $2Na_2HPO_4-H_2O=Na_4P_2O_7$; and those with two atoms of H yield metaphosphates, *e.g.*

$$NaH_2PO_4-H_2O=NaPO_3.$$

Similarly a double orthophosphate of the form M_2RPO_4 yields a pyrophosphate on heating if R forms a volatile oxide, *e.g.* $2Na_2(NH_4)PO_4=Na_4P_2O_7+H_2O+2NH_3$. The removal of M_2O from a normal orthophosphate with formation of a metaphosphate is often effected by fusing with SiO_2 or B_2O_3 or other anhydride which forms a salt with M_2O, *e.g.* $Na_3PO_4+SiO_2=NaPO_3+Na_2SiO_3$.

The metaphosphates formed by the processes sketched above belong to several series of salts all of which have the empirical formula $nMPO_3$. According to Fleitmann a. Henneberg (*A.* 65, 304; F., *P.* 78, 233, 338), these salts belong to five series.

Monometaphosphates MPO_3. Not many of these have been obtained with certainty; they are produced by heating alkaline oxides with equivalent quantities of H_3PO_4 to redness until the residue ceases to give an acid reaction (the temperature not being high enough to melt the mass), and washing the residue with cold water; some of the salts—*e.g.* $NaPO_3$ and KPO_3—are formed by heating MH_2PO_4 or $M_2H_2P_2O_7$ to redness (*c.* 315°) till the residue is almost wholly insoluble in cold water (Maddrell, *C. S. Mem.* 3, 273).

Dimetaphosphates $M_2P_2O_6$. The salts of Cu, Zn, and Mn are prepared by heating equivalent quantities of MO and H_3PO_4 to redness. The Na and NH_4 salts are obtained by decomposing the Cu salt by Na_2SAq or NH_4 sulphide solution, filtering, and ppg. by alcohol. These salts yield others of the series by double decomposition. The salts of this series are soluble in water and crystallisable. Tammann (*Z. P. C.* 6, 122) thinks these salts are really trimetaphosphates (*v. Properties and Reactions*).

Trimetaphosphates $M_3P_3O_9$. The salts of this series are crystalline. The Na salt is prepared by slowly heating $NaNH_4HPO_4$ with frequent stirring, till the residue has a faintly acid reaction, treating with cold water, filtering, and allowing the filtrate to crystallise. The salt is also formed by heating $NaNH_4HPO_4$ till a glassy mass remains, and cooling very slowly. The other salts are obtained from the Na salt by double decomposition. Tammann (*l.c.*) regards these salts as dimetaphosphates (*v. Properties and Reactions*).

Tetrametaphosphates $M_4P_4O_{12}$. PbO is heated with H_3PO_4 to redness, as in making the Cu, Zn, and Mn dimetaphosphates (*v. supra*); the crystalline salt which is formed is insoluble in water, and much more easily decomposed by acids than the Pb salt got from $Na_2P_2O_6$. The Na salt is obtained by decomposing the Pb salt by Na_2SAq; and other salts are obtained from the Pb salt by double decomposition. Salts of Bi and Cd are obtained similarly to the Pb salt. These phosphates are uncrystallisable. Tammann (*J. pr.* [2] 45, 417) says that $CuNa_2P_4O_{12}$ is the only salt which certainly belongs to this series.

Hexametaphosphates $M_6P_6O_{18}$. $NaNH_4HPO_4$ is heated till a glassy mass remains, which is cooled rapidly (Graham, *T.* 1833. 253). The Na salt yields others by double decomposition. These salts are non-crystallisable, and dry to resinous-like masses. Tammann's experiments (*l.c.*) seem to show that $Na_6P_6O_{18}$ is a mixture of several isomeric salts (*v.* p. 118).

Tammann (*l.c.*) describes salts belonging to the series of *penta-*, *okto-*, *deka-*, and *tetrakaideka- metaphosphates.*

Tetraphosphates $M_6P_4O_{13}$. A few of these salts have been prepared, *e.g.* $Na_6P_4O_{13}$ by fusing $2NaPO_3 + Na_4P_2O_7$, and $Ba_3P_4O_{13}$ by fusing the Na salt with $BaCl_2$ (F. a. H., *A.* 65, 304; Uelsmann, *A.* 118, 99).

Dekaphosphates $M_{12}P_{10}O_{31}$. The Na salt was obtained by fusing $Na_4P_2O_7 + 8NaPO_3$ (F. a. H., *l.c.*); some other salts were obtained from the Na salt by double decomposition (U., *l.c.*).

Properties and Reactions.—The *orthophosphates* MH_2PO_4 dissolve in water, forming acid solutions; the dimetallic salts M_2HPO_4 dissolve in water when M is an alkali metal, the solutions are feebly alkaline. Of the normal salts M_3PO_4, only those of the alkali metals are soluble in water; the solutions have an alkaline reaction, and are decomposed very easily, even by CO_2, forming M_2HPO_4Aq. Most of the heavy metals form only M_3PO_4. Solutions of alkali orthophosphates give a yellow pp. (Ag_3PO_4) with $AgNO_3Aq$, and a yellow pp. on warming with NH_4 molybdate solution. The orthophosphates M_3PO_4 are not decomposed by heating strongly, unless they are salts of volatile bases; M_2HPO_4 give $M_4P_2O_7$ and H_2O, and MH_2PO_4 give MPO_3 and H_2O when strongly heated. M_3PO_4, M = alkali or alkaline earth metal, are not changed by heating with charcoal, but M_2HPO_4 and MH_2PO_4 give M_3PO_4 and P. When M is a heavy metal, the salts M_3PO_4 generally give metallic phosphides by heating with C. Orthophosphates heated with K or Na yield alkali phosphide. Many insoluble orthophosphates are decomposed by fusion with alkali carbonate, but those of the alkaline earths are only partially decomposed. H_2SO_4 decomposes all orthophosphates. When the salts M_3PO_4 are heated with SO_2Aq under pressure, M_2HPO_4 or MH_2PO_4 are formed (Pitter, *Chem. Indust.* 1878. 398; Gerland, *J. pr.* [2] 4, 97).

Of the *pyrophosphates*, the normal alkali salts are soluble in water, with feebly alkaline reactions; the others are generally insoluble but dissolve in $Na_4P_2O_7Aq$, forming double salts (H. Rose, *P.* 76; 13; Schwarzenberg, *A.* 65, 183; Persoz, *A.* 65, 163). Solution of pyrophosphates give orthophosphates when boiled with the stronger acids, or heated with water to 280° (Reynoso). $M_4P_2O_7$ are not changed by heat unless they are salts of bases decomposed by heat; $M_2H_2P_2O_7$ give MPO_3 and H_2O when strongly heated. All the pyrophosphates are changed to orthophosphates by heating strongly with sufficient alkali or alkali carbonate. Pyrophosphates of metals whose oxides are not reduced by H give orthophosphates and P_2O_5 when heated in H; those which contain metals whose oxides are reduced by H, but not by heat alone, give metallic phosphide when heated in H; and those containing metals the oxides of which are reduced by heat alone, yield metal, H_2O, H_3PO_4, &c., when heated in H (Struve, *J. pr.* 79, 345). Pyrophosphates in solution give a white pp. with $AgNO_3Aq$; they do not give an immediate pp. with warm NH_4 molybdate, and they do not coagulate albumen when acidified by acetic acid.

Some *metaphosphates* are soluble, others are insoluble, in water; some are crystalline, others are amorphous (*v. supra*: *Formation of different classes of metaphosphates*). Solutions of these salts in water are changed to orthophosphates on long-continued boiling; they give a white pp. with $AgNO_3Aq$, no immediate pp. with NH_4 molybdate, and they coagulate albumen after acidification by acetic acid.

Tammann (*Z. P. C.* 6, 123) has examined the electrical conductivities of solutions of Fleitmann's di- and tri- metaphosphates of Na; his results indicate that the ions of the salts in solution are Na_x and $(PO_3)_x$. He has also measured the depression produced in the freezing-point of water by dissolving these salts therein; and, taking the results along with the electrical conductivities, he concludes that Fleitmann's di-salts are tri- salts, and F.'s tri- salts are really di- salts. By the reaction of $AgNO_3Aq$ on the $Na_6P_6O_{18}$ of Graham and Fleitmann, Tammann obtained a crystalline salt $Ag_6P_6O_{18}$, and two salts $Ag_4Na_2P_6O_{18}$ and $Ag_5NaP_6O_{18}$, and from these he formed three Na salts which he formulates as $Na_6P_6O_{18}$, $Na_4.Na_2.P_6O_{18}$, and $Na_5.Na.P_6O_{18}$. Measurements of the electrical conductivities of these salts confirm the above formulæ, and they tend to show that the ions of the salts in solution are Na_4 and $Na_2P_6O_{18}$, and Na_5 and NaP_6O_{18} respectively. A fuller examination of Graham's salt led T. to conclude that it contains another isomeric hexametaphosphate $Na_2.Na_4.P_6O_{18}$.

For *detection and estimation* of phosphates a manual of analysis must be consulted.

ORTHOPHOSPHATES. *Salts derived from* H_3PO_4. (For *thioxyorthophosphates v.* PHOSPHORIC SULPHIDE, p. 147.)

Aluminium orthophosphates. Many occur in minerals, *e.g. angelite, fischerite, wavellite, turquois.* The pps. obtained by adding Na_2HPO_4Aq to alum solutions vary in composition. They may be represented as xAl_2O_3, yP_2O_5, x being chiefly 1, 2, 3, and y being 1 and 2 (Munroe, *A.* 159, 638; Wittstein, *J. B.* 27, 167; Fuchs, *S.* 24, 121; Millot, *C. R.* 82, 89).

The *normal salt*, $AlPO_4.xH_2O$, is obtained by gradually pouring neutral alum solution into excess of Na_2HPO_4Aq; a white loose powder; soluble mineral acids, soluble organic acids, soluble NH_4 citrate solution (Erlenmeyer, *B.* 14, 1869), soluble Al salt solution (Fleischer, *Fr.* 6, 28), soluble in potash; infusible at red heat, fused with Fe and SiO_2 gives Fe phosphide (Schlösing, *C. R.* 67, 1247); partially decomposed by fusing with K_2CO_3 (Rammelsberg, *P.* 64, 405; *cf.* Vauquelin, *A. Ch.* [2] 21, 138). When air-dried $x = 4$ to 5; dried over H_2SO_4, $x = 8$ (Rammelsberg, Millot, Wittstein). For other phosphates of Al *v.* Rammelsberg (*l.c.*), Schweitzer (*B.* 3, 310; 6, 28), Ludwig (*Ar. Ph.* [2] 59, 19), Hautefeuille a. Margottet (*C. R.* 106, 135), Erlenmeyer (*Z.* 3, 572).

Double salts with phosphates of Ca, Li, and Mg have been described (*v. Gm.-K.*, i. 2, 670).

Ammonium orthophosphates. The *normal salt*, $Am_3PO_4.3H_2O$, crystallises in short pyramids, obtained by treating Am_2HPO_4 with conc. NH_3Aq (Berzelius, *Gm.-K.* i. 2, 527). Loses two-thirds NH_3 by boiling water (Kraut, *C. C.* 1855. 894). Sestini (*B.* 11, 1927) obtained a salt with $5H_2O$. The *di-ammonium salt*, Am_2HPO_4, is formed in monoclinic prisms by allowing NH_3 or $(NH_4)_2CO_3$ in H_3PO_4Aq to evaporate; soluble four parts cold water, solution is alkaline; on boiling NH_3 is evolved; S.G. 1·62–1·67 (Rammelsberg, *B.* 3, 278; Schiff, *A.* 112, 88; Buignot, *J.* 1861. 15; Proust a. Brooke, *Gm.-K.* i. 2, 528). The *mon-ammonium salt*, AmH_2PO_4, crystallises in quadratic forms, isomorphous with KH_2PO_4, by adding NH_3Aq to H_3PO_4Aq till $BaCl_2Aq$ ceases to give a pp. S.G. 1·758 (Schiff, *l.c.*; Mitscherlich, *P.* 19, 385).

Barium orthophosphates. The *normal salt*, $Ba_3P_2O_8$, is a heavy white solid, obtained by ppg. $BaCl_2Aq$ by Na_3PO_4Aq (Graham; Rotondi, *B.* 15, 1441). Two *acid salts* have been obtained: (1) $BaHPO_4$, by boiling the normal salt with H_3PO_4Aq, or by ppg. $BaCl_2Aq$ by Na_2HPO_4Aq soluble in 10,000 to 20,000 parts water, easily soluble if NH_4 salts, $BaCl_2$, or NaCl is present; soluble in H_3PO_4Aq or dilute HNO_3Aq (Berzelius, Ludwig, Rose, Brett, Wittstein, Bischoff, Malaguti, *Gm.-K.* i. 2, 272; Skey, *C. N.* 22, 61; Erlenmeyer, *J.* 1857. 145; Setschenoff, *C. C.* 1875. 97; Gerland, *J. pr.* [2] 4, 125); (2) $BaH_4P_2O_8$, from a solution of $BaHPO_4$ in H_3PO_4; white triclinic crystals; decomposed by much water to H_3PO_4Aq and $BaHPO_4$ (Berzelius).

Double salts.—(1) $3Ba_3P_2O_8.BaCl_2$ (Rose, *P.* 8, 211; Ludwig, *Ar. Ph.* [2] 56, 265; Deville a. Caron, *A. Ch.* [3] 67, 451);
(2) $4BaHPO_4.BaCl_2$ (Erlenmeyer, *J.* 1857. 145);
(3) $BaNaPO_4.10H_2O$ (Rose, Guyton, Berzelius, *Gm.-K.* i. 2, 313; de Schulten, *Bl.* [2] 39, 500; Joly, *C. R.* 104, 1702); (4) $BaKPO_4.10H_2O$ (de S., *l.c.*).

Beryllium orthophosphates. The *normal salt*, $Be_3P_2O_8$, is a white pp., obtained by adding Na_2HPO_4Aq to solution of a salt of Be. An *acid salt* is obtained by dissolving the normal salt in H_3PO_4Aq (Vauquelin, *Gm.-K.* i. 2, 269).

Double salts. $Be.NH_4$ and Be.K phosphates are known (Rössler, *Fr.* 1878. 148; Ouvrard, *C. R.* 110, 1333).

Bismuth orthophosphate $BiPO_4$. White powder, obtained by adding $Bi_2O_3.xH_2O$ to H_3PO_4Aq; little known (Wenzel, *Gm.-K.* i. 2, 832; Chancel, *C. R.* 50, 416).

Cadmium orthophosphates. The *normal salt*, $Cd_3P_2O_8$, is obtained as an amorphous pp. by adding Na_3PO_4Aq to a Cd salt solution (de Schulten, *Bl.* [3] 1, 473).

Acid salts (de S., *l.c.*): (1) $Cd_5H_2P_4O_{16}.4H_2O$, by ppg. hot $CdCl_2Aq$ by Na_2HPO_4Aq.
(2) $CdH_4P_2O_8.2H_2O$, by dissolving the foregoing salt in cold dilute H_3PO_4Aq and allowing to evaporate at ordinary temperature.

Double salt $3Cd_3P_2O_8.CdCl_2$ (de S., *l.c.*).

Calcium orthophosphates. Ca phosphates are widely distributed minerals.

Normal salt $Ca_3P_2O_8$. Obtained, as a white amorphous powder, by adding NH_3Aq to solution of bone-ash in HClAq or HNO_3Aq; by adding Na_3PO_4Aq, or a mixture of Na_2HPO_4Aq and NH_3Aq, to $CaCl_2Aq$. For details of preparation from *phosphorite*, or bone-ash, &c. *v.* DICTIONARY OF APPLIED CHEMISTRY. The pp. from $CaCl_2Aq$ in presence of NH_3 contains $5H_2O$ according to Wittstein (*J.* 1866. 168; *v.* also Ludwig, *Ar. Ph.* [2] 69, 286). Slightly soluble in water; one litre cold water dissolved 79 mgm. freshly ppd., and 31 mgm. strongly heated, $Ca_3P_2O_8$ (Völcker, *J.* 1862. 131). Decomposed slowly by boiling water into $CaH_4P_2O_8$ and $2Ca_3P_2O_8.CaO_2H_2$ (Warington, *C. J.* [2] 11, 983). Solubility in water is increased by small quantities of alkali salts (*v.* Wöhler, *P.* 4, 166; Liebig, *A.* 61, 128; Lassaigne, *J.* 1847. 341; Thomson, *Ann. Philos.* 17, 12; Völcker, *J.* 1862. 131; Fresenius, *Fr.* 10, 133; Hünefeld, Delkeskampf, Morveau, *Gm.-K.* i. 2, 367; Terreil, *Bl.* [2] 35, 548; Erlenmeyer, *B.* 14, 1253). Presence of starch and various organic substances increases solubility in water (*v.* Wöhler, *A.* 98, 143; Hayes, *N. Ed. P. J.* 5, 378). Soluble in CO_2Aq; $CaCO_3$ and $CaHPO_4$ separate on standing (Liebig, *A.* 106, 196; Warington, *C. J.* [2] 4, 296; Dusart a. Pelouze, *C. R.* 66, 1327; von Georgievics, *M.* 12, 566).

Partially decomposed by boiling with NaOHAq, or by fusing with Na_2CO_3 (Wöhler, *A.* 51, 437; Rose, *P.* 95, 437; Fresenius, *Fr.* 10, 133). Easily changed to CaC_2O_4 by boiling with $(NH_4)_2C_2O_4Aq$ (Fresenius, *l.c.*).

Strongly heated with C and SiO_2, gives Ca silicate, P, and CO; heated in CO, all P is set free (Schlösing, *C. R.* 59, 384; Anderson, *B.* 5, 1065). Heated with Na, K, or Mg, metallic phosphide is formed (*v. Gm.-K.* i. 2, 366).

Dissolved by SO_2Aq; on standing, $CaHPO_4$ and $CaSO_3$ separate (*v.* Gerland, *C. N.* 20, 268; Aldred, *C. N.* 42, 177; Rotondi, *B.* 15, 1441). Dilute H_2SO_4Aq forms $CaHPO_4$, or $CaH_4P_2O_8$, or $CaSO_4$ and H_3PO_4, according to the quantities of H_2SO_4 and $Ca_3P_2O_8$, the temperature, and the time of action (*v. Gm.-K.* i. 2, 369; Kolb, *C. R.* 78, 825; Joulie, *C. R.* 76, 1288; Crum, *A.* 63, 394). For the (similar) reactions with HClAq and HNO_3Aq *v.* Crum, *l.c.*; Piccard (*J.* 1886. 468); Bischof (*S.* 67, 39); Birnbaum a. Packard (*Z.* [2] 7, 137); Tissier (*C. R.* 38, 192); Warington (*C. J.* [2] 4, 302).

Double salts. (1) $Ca_3P_2O_8.Ca_2SiO_4$ (Carnot a. Richard, *C. R.* 97, 316). (2) $3Ca_3P_2O_8.CaCl_2$ by fusing $Ca_3P_2O_8$ with NaCl, or heating to 250° with $CaCl_2Aq$, or passing PCl_3 vapour over glowing lime (Forchhammer, *P.* 91, 568; Debray, *A. Ch.* [3] 61, 424; Daubrée, *Ann. M.* (4) 19, 684; Deville a. Caron, *A. Ch.* [3] 67, 451). (3) $3Ca_3P_2O_8.CaF_2$; occurs native as *apatite* (with varying quantities of $CaCl_2$); obtained by fusing Na_2HPO_4, CaF_2, and $CaCl_2$ (D. a. C., *l.c.*; Briegler, *A.* 97, 95). (4) $Ca(NH_4)PO_4.xH_2O$ (Herzfeld a. Feuerlein, *Fr.* 1881. 191). (5) $CaKPO_4$ (Rose, *P.* 77, 291). (6) $CaLiPO_4$ (Rose, *P.* 77, 298). (7) $CaNaPO_4$ (Rose, *P.* 77, 291; Bunge, *A.* 172, 18).

Acid salts. I. *Dicalcium phosphate* $Ca_2H_2P_2O_8$. Obtained by adding Na_2HPO_4Aq, or $NaNH_4HPO_4Aq$, to excess of $CaCl_2Aq$; pp. contains a little $Ca_3P_2O_8$: also by the action of CO_2Aq on $CaCO_3$ and $(NH_4)_2HPO_4Aq$ (Becquerel, *C. R.* 34, 573); and by acting on powdered $CaCO_3$ with H_3PO_4Aq (Debray, *A. Ch.* [3] 61, 424); by passing CO_2 into H_2O, holding freshly ppd. $Ca_3P_2O_8$ in suspension (Percy, *P. M.* [3] 26, 194; Reichardt, *Ar. Ph.* [3] 2, 236). Obtained in crystals by allowing solutions of $(NH_4)_2HPO_4$ and $CaCl_2$ to mix slowly through a porous cell (Vohl, *A.* 88, 114), or through a layer of water (Drevermann, *A.* 87, 120); also by allowing a solution of amorphous $CaHPO_4$ in a weak acid to evaporate (Bödeker, *A.* 69, 206; Baer, *P.* 75, 152; Vorbringer, *Fr.* 9, 457; *v.* also Causse, *J. Ph.* [5] 21, 544). $CaHPO_4$ ppd. at low temperatures and dried quickly at 100° contains $2H_2O$, which is lost by long drying at 100° in a stream of dry air. Forms $Ca_2P_2O_7$ when strongly heated; decomposed to $Ca_3P_2O_8$ and $CaH_4P_2O_8$ by long boiling with water. For description of various hydrates $xCaHPO_4.yH_2O$ *v.* Vorbringer (*Fr.* 9, 457), Gerland (*J. pr.* [2] 4, 104), Millot (*Bl.* [2] 33, 194), Skey (*C. N.* 22, 61), Dusart a. Pelouze (*C. R.* 66, 1327), Davies (*C. N.* 64, 287). Soluble in boiling NH_4ClAq (Kraut, *Ar. Ph.* [2] 111, 102); soluble SO_2Aq (Gerland, *J. pr.* [2] 4, 123), in HClAq and HNO_3Aq (Berzelius, Baer, *Gm.-K.* i. 2, 372). Decomposed by boiling alkali carbonate solutions (Malaguti, *Gm.-K.* i. 2, 373).

II. *Monocalcium phosphate* $CaH_4P_2O_8.H_2O$. This salt is the chief constituent of artificial '*superphosphate of lime*' prepared by treating crushed bones, *phosphorite*, &c., with H_2SO_4 (*v.* DICTIONARY OF APPLIED CHEMISTRY). Prepared by dissolving $Ca_2H_2P_2O_8$ in 81 p.c. H_3PO_4Aq, crystallising, washing with absolute alcohol, then with ether, and drying (Stoklasa, *Listy Chem.*, 13, 203, 240, 273; abstract in *C. J.* 58, 695). This salt is also formed by evaporating $Ca_2H_2P_2O_8$ with $HNO_3Aq + H_2SO_4Aq$. Also by leaving a solution of the commercial honey-like monocalcium phosphate in contact with $Ca_3P_2O_8$ for some time, and evaporating the solution formed at a gentle heat; the salt is thus obtained in crystals (Pointet, *Bl.* [3] 5, 254). Not hygroscopic; the hygroscopic nature of the preparation made by Birnbaum and others is said by Stoklasa (*l.c.*) to be due to traces of H_3PO_4. Thin rhombic plates (*v.* Haushofer, *Z. K.* 7, 263); S.G. 2·02 (Schröder, *B.* 11, 126). Loses H_2O at 100°, decomposes at 200° to mixture of CaP_2O_6 and $Ca_2P_2O_7$ (Birnbaum, *B.* 6, 898). Decomposed by H_2O. Stoklasa (*l.c.*) represents the decomposing action of water as

$$xCaH_4P_2O_8.H_2O + H_2O$$
$$= (x-1)CaH_4P_2O_8.H_2O + CaHPO_4 + 2H_2O + H_3PO_4;$$

the greater the quantity of water the more salt is dissolved without decomposition; with 200 parts H_2O to 1 part salt a clear solution is formed without any free H_3PO_4; above this limit $CaH_4P_2O_8$ is re-formed from the products of its decomposition (for older observations *v.* Birnbaum, *l.c.*; Erlenmeyer, *N. J. P.* 7, 225; Warington, *Fr.* 1880. 243). According to Reynoso (*C. R.* 34, 795), water at 280° decomposes the salt, forming H_3PO_4 and crystalline $Ca_3P_2O_8$. Various salts produce $Ca_2H_2P_2O_8$ from solutions of $CaH_4P_2O_8$ (*v.* Debray, *A. Ch.* [3] 61, 424; Dusart a. Pelouze, *C. R.* 66, 1327; Vorbringer, *Fr.* 9, 457; Erlenmeyer, *l.c.*; Birnbaum, *l.c.*).

Cerium orthophosphate $CePO_4$. By fusing Ce_2O_3 with KPO_3; also by digesting $Ce_2K_3(PO_4)_3$ with KClAq. Monoclinic prisms; S.G. 3·8 (Ouvrard, *C. R.* 107, 37). The *double salt* $Ce_2K_3(PO_4)_3$ is formed by fusing K_3PO_4 or $K_4P_2O_7$ with Ce_2O_3.

Chromium orthophosphates. The *normal chromic salt*, $Cr_2P_2O_8$, is known in two forms, green and violet. *Violet form*, $Cr_2P_2O_8.12H_2O$, a violet crystalline pp. by adding Na_2HPO_4Aq to excess of Cr alum solution; loses $7H_2O$ at 100°, becoming green; changed to green by conc. HNO_3Aq, H_2SO_4, or PCl_3 (Rammelsberg, *P.* 68, 383; Etard, *C. R.* 84, 1091). *Green form*, $Cr_2P_2O_8.6H_2O$, by adding excess of Na_2HPO_4Aq to Cr alum; also by ppg. a slightly acid solution of a Cr salt by Na_2HPO_4 and Na acetate (Rose, *P.* 77, 291, 298; Carnot, *Bl.* [2] 37, 482; Vauquelin, *Gm.-K.* i. 2, 304). Soluble mineral acids, also KOHAq (*v.* Dowling a. Plunkett, *Chem. Gazette*, 1858. 220; Kämmerer, *Fr.* 12, 375). Gives alkali chromates by fusion with alkali sulphates (Grandeau, *C. R.* 95, 921). Forms a *double salt* with Ca (Dingler, *D. P. J.* 212, 532; Plessy, *Rép. Chim. app.* 1862. 453; Köthe, *D. P. J.* 214, 59). The *acid salt* $CrH_4P_2O_8.8H_2O$ is probably formed by dissolving $Cr_2O_3.xH_2O$ in H_3PO_4Aq (Vauquelin, *Gm.-K.* i. 2, 304; Haushofer, *Z. K.* 7, 263).

Chromous orthophosphate $Cr_3P_2O_8.H_2O$, a blue pp. by adding Na_2HPO_4Aq to $CrCl_2Aq$;

quickly becomes green in air (Moissan, *A. Ch.* [5] 25, 401).

Cobalt orthophosphates. The *normal salt* $Co_3P_2O_8.xH_2O$ is formed by heating $CoHPO_4.3H_2O$ with water, or with $Co(NO_3)_2Aq$, to 250° in a sealed tube (Debray, *A. Ch.* [3] 61, 438); also by treating $Co(NH_4)PO_4.6H_2O$ with boiling water (Chancel, *Précis d'analyse* [Paris, 1862] 1, 263). In this salt $x = 2$. A salt with $x = 8$ is said to be formed by ppg. $CoH_4P_2O_8Aq$ by alcohol (Reynoso, *C. R.* 34, 795; Reitler, *Vierteljahr. Pharm.* 7, 246). Two *acid salts* are known: (1) $CoHPO_4.3H_2O$, by boiling $CoCO_3$ with H_3PO_4Aq, or boiling solution of a Co salt with $CaH_4P_2O_8$ (Debray, *J. Ph.* [3] 46, 121); a salt with $5H_2O$ was obtained by Bödeker (*A.* 94, 357). (2) $CoH_4P_2O_8$, by heating Co pyrophosphate with water to 280° (Reynoso, *C. R.* 34, 795). *Double salts*: NH_4 salts *v.* Dirvell, *C. R.* 89, 903; Popp, *Z.* [2] 6, 305. For luteo- and roseo- cobaltamine phosphates *v.* Gibbs a. Genth, *Am. S.* [2] 21, 86; 23, 234, 319; Braun, *Gm.-K.* i. 3, 463; Porumbaru, *C. R.* 93, 342. For K and Na double salts *v.* Ouvrard, *C. R.* 106, 1729.

Copper orthophosphates. *Normal salt* $Cu_3P_2O_8.3H_2O$, obtained by adding a little Na_2HPO_4Aq to excess of a Cu salt solution (Mitscherlich, *Gm.-K.* i. 3, 614); also by heating $CuCO_3$ with H_3PO_4Aq to 70° (Debray, *A. Ch.* [3] 61, 437). A blue-green powder; decomposed by hot water under pressure (Debray; *v.* also Reynoso, *C. R.* 34, 1795; Jörgensen, *Gm.-K.* i. 3, 615). *Basic salts* and *acid salts* are known; composition doubtful (*v.* Rammelsberg, *P.* 68, 383; Metzner, *A.* 149, 67). For *double salts* with NH_4 *v.* Metzner, *l.c.*, and Schiff, *A.* 123, 41; with Na, *v.* Weineck, *A.* 156, 57; with K, also with Na, *v.* Ouvrard, *C. R.* 111, 177. For an account of the salts produced by the reaction of Na_2HPO_4Aq with $CuSO_4Aq$ and $Cu(NO_3)_2Aq$ *v.* Steinschneider, *C. C.* 1891, ii. 51 (abstract in *C. J.* 60, 1423).

Didymium orthophosphate $DiPO_4$: also double salts with alkali metals (Ouvrard, *C. R.* 107, 37).

Iron orthophosphates. Ferrous salts. The *normal salt* $Fe_3P_2O_8.8H_2O$ occurs native as *vivianite*; it is obtained by ppg. $FeSO_4Aq$ with excess of Na_2HPO_4Aq, and digesting at 60°-80° for eight days. Small monoclinic crystals (Rammelsberg, *P.* 64, 251, 405), nearly colourless but becoming blue in air (Debray, *C. R.* 59, 40). A salt with one H_2O is obtained by heating $Fe_2H_2P_2O_8.4H_2O$ with water at 250° (Debray, *A. Ch.* [3] 61, 437). Various *acid salts* are obtained by dissolving Fe in H_3PO_4Aq; if the materials are air-free, and evaporation is effected in CO_2, the salt $Fe_2H_2P_2O_8.4H_2O$ is formed (Erlenmeyer, Debray, Rammelsberg, *l.c.*). For *double salts* with NH_4, *v.* Otto, *J. pr.* 2, 409; and Debray, *C. R.* 59, 40.

Ferric salts. The *normal salt* $FePO_4$ is obtained by ppg. $FeCl_3Aq$ by Na_2HPO_4Aq; dried at 50° contains $8H_2O$, at 100° contains $4H_2O$, dehydrated by heating strongly; also formed by oxidation in air of $Fe_3P_2O_8$ (Debray, Rammelsberg, Wittstein, *l.c.*). Whether the salt ppd. from $FeCl_3Aq$ in presence of acetic acid is the normal or a basic salt is undecided (*v.* Winkler, *J. prakt. Pharm.* 5, 337; Heydenrich, *C. N.* 4, 158; Struve, *N. Peters. Acad. Bull.* 1, 465; Wackenroder a. Ludwig, *Ar. Ph.* [2] 53, 1; Mohr *Fr.* 2, 520). $FePO_4.xH_2O$ is sol. c. 1500 parts boiling water; but is decomposed (Lachowicz, *M.* 13, 357). *Acid salts* are obtained by dissolving $Fe_2O_3.xH_2O$ in H_3PO_4Aq: Erlenmeyer got $FeH_6P_3O_{12}$ by evaporating quickly (*v.* also Waine, *C. N.* 36, 132; Wagner, *Chem. Zeitung*, 1881. 247). Hautefeuille a. Margottet (*C. R.* 106, 1357) obtained various ferric phosphates by dissolving $Fe_2O_3.xH_2O$ in glacial phosphoric acid.

Lanthanum orthophosphate $LaPO_4$: also double salts with K and Na (*v.* Ouvrard, *C. R.* 107, 37).

Lead orthophosphates. The *normal salt*, $Pb_3P_2O_8$, is ppd. as a white powder by adding Na_2HPO_4Aq to Pb acetate solution (Berzelius; Mitscherlich, *Gm.* 3; *v.* also Heintz, *P.* 73, 119; Gerhardt, *A. Ch.* [3] 22, 505; Haushofer, *Z. K.* 7, 264). A *double salt* with $PbCl_2$ is obtained by action of Na_2HPO_4Aq on $PbCl_2$ (Debray, *A. Ch.* [3] 61, 419; Manross, *A.* 82, 348; Deville a. Caron, *A. Ch.* [3] 67, 451). By ppg. boiling $Pb2NO_3Aq$ by H_3PO_4Aq, Heintz (*P.* 73, 119) obtained the *acid salt* $Pb_2H_2P_2O_8$.

Lithium orthophosphates. The *normal salt*, $Li_3PO_4.H_2O(?2Li_3PO_4.H_2O)$. By heating Na_2HPO_4Aq with solution of a salt of Li (Mayer, *A.* 98, 183; *v.* also Berzelius, *P.* 4, 245; Rammelsberg, *C. N.* 38, 240, also *B.* 15, 283; Fresenius, *Fr.* 1, 42; Kraut, *A.* 182, 165). Loses H_2O at 100°. Obtained in rhomboidal tables, S.G. 2·41 at 15°, by dissolving in fused LiCl (de Schulten, *Bl.* [3] 1, 479). Soluble in c. 2,540 parts water. *Acid salts*: LiH_2PO_4 and $LiH_5P_2O_8.H_2O$, by dissolving normal salt in H_3PO_4Aq (Rammelsberg, *l.c.*).

Magnesium orthophosphates. The *normal salt*, $Mg_3P_2O_8.xH_2O$, is obtained with $4H_2O$ by ppg. Mg salts by alkali phosphate and drying at 100° (Graham; Rose, *P.* 76, 84; Gregory, *A.* 54, 98; Stein a. Tollens, *A.* 187, 79; Fresenius). Forms monoclinic crystals (Haushofer, *Z. K.* 6, 137). Very slightly soluble water (Völker, *J.* 1862. 131). For solubility in salt solutions *v.* Liebig (*A.* 106, 185), and in citric acid *v.* Erlenmeyer (*B.* 14, 1253). Soluble SO_2Aq (Gerland, *J. pr.* [2] 4, 126; Rotondi, *B.* 15, 141). Crystals with $6H_2O$ separate from $MgSO_4Aq + Na_2HPO_4Aq$ at 36° and upwards; and at lower temperatures a salt with $14H_2O$ is obtained (*v.* Percy, *P. M.* [3] 26, 194; Reischauer, *N. R. P.* 12, 43; 14, 57).

Acid salts. 1. $MgHPO_4.xH_2O$ ($x = 6,7,8,9$); by dissolving *magnesia alba* in H_3PO_4Aq (Bergmann, Fourcroy, *Gm.-K.* i. 2, 446; Debray, *J. pr.* 97, 116; Haushofer, *Z. K.* 7, 257).—2. $MgH_4P_2O_8$; by boiling the foregoing acid salt with water (Schaffner; Rotondi, *B.* 15, 141).

Double salts. Magnesium-ammonium orthophosphate $MgNH_4PO_4.6H_2O$. By adding Na_2HPO_4Aq to a Mg salt to which NH_4ClAq and excess of NH_3Aq have been added; or by adding a mixture of H_3PO_4Aq and excess of NH_3Aq to a Mg salt. For experiments on different conditions of formation *v.* Graham (*A.* 29, 25); Riffault (*A. Ch.* [2] 19, 90); Mohr (*Fr.* 12, 36); Gibbs (*C. N.* 28, 51); Lesieur (*C. R.* 59, 191); Stein a. Tollens (*Gm.-K.* 1, 2, 476); Kubel (*Fr.* 8, 125); Kissel (*Fr.* 8, 164); Brunner (*Fr.* 11, 30); Berzelius (*P.* 4, 275); Heintz (*Fr.* 9, 16). Obtained in large crystals by separating the reacting liquids by a membrane (Vohl, *A.* 88, 114; Nonier, *C. R.* 78, 800; Millot, *Bl.* [2] 18, 20; Millot a. Maquenne, *Bl.* [2] 23, 238). Loses NH_3 in air; strongly heated gives $Mg_2P_2O_7$. For solubility in various solutions *v.* Fresenius (*A.* 55, 109); Ebermayer (*J. pr.* 60, 41); Liebig (*A.* 106, 196); Völcker (*J.* 1862. 131); Kissel (*Fr.* 8, 173); Gerland (*J. pr.* [2] 4, 127); Millot (*Bl.* [2] 18, 20); Ville (*C. R.* 75, 344). Another Mg-NH_4 phosphate is described by Gawalovski (*C. C.* 1885. 721). For other double salts: with $MgCl_2$, *v.* Deville a. Caron (*A. Ch.* [3] 67, 456); with $MgCl_2$ and MgF_2, *v.* Bischof (*D. P. J.* 237, 51, 136); with $MgCl_2$ and CaF_2, *v.* D. a. C. (*l.c.*); with K, *v.* Haushofer (*Z. K.* 7, 257), Ouvrard (*C. R.* 106, 1729); with Na, *v.* Rose, Berzelius, &c. (*Gm.-K.* i. 2, 476), Ouvrard (*l.c.*).

Manganese orthophosphates. *Normal manganic orthophosphate*, $MnPO_4.H_2O$, a greenish grey pp. by adding conc. $Mn(NO_3)_2Aq$ to H_3PO_4 and a little boiling water (Christensen, *J. pr.* [2] 28, 1). For properties of products of reaction of H_3PO_4 on manganates and permanganates *v.* Laspeyeres (*J. pr.* [2] 15, 320); Hermann (*P.* 74, 303); Rose (*P.* 105, 289); Barreswill (*C. R.* 44, 677); Hoppe-Seyler (*J. pr.* 90, 303).

Normal manganous orthophosphate, $Mn_3P_2O_8.xH_2O$. Obtained with $14H_2O$ by ppg. $MnSO_4Aq$ by Na_2HPO_4Aq; loses $7H_2O$ over H_2SO_4, and one more H_2O at 100° (Erlenmeyer, *A.* 190, 208). Salts with 9 to 11 H_2O, $7H_2O$, and $3H_2O$ are obtained by decomposing $MnHPO_4.xH_2O$ by water, and drying under different conditions (E., *l.c.*). The salt without H_2O is formed by strongly heating the hydrates, also by heating $Mn_2P_2O_7$ in H (Struve, *J.* 1860. 73). A white amorphous pp., soluble mineral acids and acetic acid, and various salt solutions (*v.* Berzelius, *Gm.-K.* i. 2, 472; Heintz, *P.* 74, 449; Joulin, *A. Ch.* [4] 30, 272; Gerland, *J. pr.* [2] 4, 97; Wittstein, *Gm.-K.* 2, 472; Braun, *Fr.* 7, 340; Erlenmeyer, *B.* 14, 1253).

Various *acid salts* have been described:—1. $MnHPO_4.3H_2O$ (Bödeker, *A.* 69, 206; Heintz, *P.* 74, 449; Erlenmeyer, *A.* 190, 208).—2. $MnH_4P_2O_8.2H_2O$ (Heintz, Erlenmeyer, *l.c.*).—3. $Mn_3P_2O_8.MnHPO_4.xH_2O$ (Erlenmeyer, *l.c.*; Haushofer, *Z. K.* 7, 257). *Double salts*: with $MnCl_2$ (Deville a. Caron, *A. Ch.* [3] 67, 459); with $Fe_3P_2O_8$ and $MnCl_2$, and with $Fe_3P_2O_8$ and MnF_2 (D. a. C., *l.c.*); with NH_4 (Otto, *S.* 66, 288; Heintz, *l.c.*); with K and with Na (Ouvrard, *C. R.* 106, 1729).

Mercury orthophosphates. *Normal mercurous orthophosphate*, Hg_3PO_4, by ppg. excess of Na_2HPO_4Aq by $HgNO_3Aq$ (Gerhardt, *J.* 1849. 283). Brooks (*P.* 66, 63) describes a *basic salt*. A *double salt* with $HgNO_3$ is described by Gerhardt (*l.c.*; *v.* also *Gm.-K.* 3, 918). *Normal mercuric orthophosphate*, $Hg_3P_2O_8$, is obtained by heating Hg_3PO_4 to low redness, also by adding strongly acidified $Hg(NO_3)_2Aq$ to Na_2HPO_4Aq (*v. Gm.-K.* 3, 754, 918; also Haack, *C. C.* 1890. [2] 736). For a *double salt* $Hg.NH_2Hg_2O.PO_4$ *v.* Hirzel (*Gm.-K.* 3, 820).

Nickel orthophosphates. The *normal salt* $Ni_3P_2O_8.7H_2O$ is obtained as a green flocculent pp. by adding Na_2HPO_4Aq to a Ni salt; heated strongly loses $7H_2O$ (Rammelsberg, *P.* 68, 383; Struve, *Gm.-K.* 3, 543). *Double salts*: with NH_4 (Debray, *C. R.* 59, 40); with Mg (Rose, *Gm.-K.* 3, 568); with Na and with K (Debray, *l.c.*; Ouvrard, *C. R.* 106, 1729).

Potassium orthophosphates. *Normal salt* K_3PO_4. A white solid, obtained by adding excess of K_2CO_3 to H_3PO_4Aq, and evaporating; slightly soluble cold water, more soluble hot water. *Acid salts*: 1. K_2HPO_4 (Graham, Funke, *Gm.-K.* 2, 30). 2. KH_2PO_4; by dissolving K_2CO_3 in so much H_3PO_4Aq that blue litmus paper is turned red but goes blue again on drying. Colourless tetragonal crystals; very soluble water; at red heat gives KPO_3; S.G. 2·29 to 2·4 (*v. Gm.-K.* 2, 30; also Senarmont, *A. Ch.* [3] 33, 391; Schiff, *A.* 112, 88; Buignet, *J.* 1861. 15).

Silver orthophosphates. *Normal salt* Ag_3PO_4, a yellow solid, obtained by adding an alkali phosphate to $AgNO_3Aq$ (Wetzlar, *Gm.-K.* 3, 918; Skey, *C. N.* 22, 61; Lassaigne, *J. Ph.* [3] 16, 289; Joly, *C. R.* 103, 1071). The *acid salt* Ag_2HPO_4 forms, in white hexagonal crystals, from a solution of the normal salt in H_3PO_4Aq (Berzelius, *P.* 2, 163; Hurtzig a. Geuther, *A.* 111, 160; Schwarzenberg, *A.* 65, 162; Joly, *C. R.* 103, 1071).

Sodium orthophosphates. The *normal salt*, $Na_3PO_4.12H_2O$, is obtained by adding excess of NaOHAq to Na_2HPO_4Aq and evaporating. Six-sided pyramids; melt at 77°; S.G. 1·618 (Schiff, *A.* 112, 18); soluble in 2 pts. water at 15°; solution absorbs CO_2 from air, giving Na_2HPO_4Aq. The anhydrous salt, Na_3PO_4, is obtained by heating the salt with $12H_2O$, or by heating $Na_2HPO_4.12H_2O$ with NaOH in equal molecular proportions (Graham, Mitscherlich, *Gm.-K.* 2, 163). S.G. 2·511 at 12°, 2·536 at 17·5° (Clarke's *Table of Specific Gravities*). For experiments on diffusion of the different Na orthophosphates *v.* van Bemmelen, *B.* 11, 1675; Hinteregger, *B.* 11, 1619; Tobias, *B.* 15, 2452.

Disodium hydrogen orthophosphate $Na_2HPO_4.12H_2O$. (*Ordinary sodium phosphate.*) Occurs in urine of carnivorous animals. Prepared by adding a slight excess of Na_2CO_3 to H_3PO_4Aq, and crystallising. (For preparation from bone-ash &c. *v.* DICTIONARY OF APPLIED CHEMISTRY.)

Colourless, rhombic, prisms; for measurements *v.* Senarmont, *A. Ch.* [3] 33, 391. S.G. 1·5235 at 16° (*v. Gm.-K.* 2, 165); melts at 35° (Kopp, *A.* 93, 129; *v.* also *Gm.-K.* 2, 165); effloresces in air, losing $5H_2O$.

Solubility in water (Mulder, *Gm.-K.* 2, 165).

Saturated Na_2HPO_4Aq boils at 105°, and freezes at −·45° (Rüdorff). S.G. of Na_2HPO_4Aq at 19° (Schiff, *A.* 110, 70); 2 p.c. = 1·0083, 4 p.c. = 1·0166, 6 p.c. = 1·025, 8 p.c. = 1·0332, 10 p.c. = 1·0418, 12 p.c. = 1·0503 (p.c. of $Na_2HPO_4.12H_2O$). S.G. solution saturated at 15° = 1·0469, at 16° = 1·0511

(Michel **a. Kraft, Stolba,** *Gm.-K.* 2, 166). **Loses** $12H_2O$ ***in vacuo*** **over** H_2SO_4, **or by heating to** 100°; **a** salt with $7H_2O$ crystallises from Na_2HPO_4Aq at 33° (Blücher, Mulder, Clark, *Gm.-K.* 2, 166). For vapour-pressure of water-gas when the salt is warmed *v.* Debray (*C. R.* 66, 195), Horstmann (*A. Suppl.* 8, 125), Pfaundler (*B.* 4, 773). For change of volume on melting *v.* Wiedemann (*W.* 17, 561).

Absorbs HCl, probably forming NaH_2PO_4 and NaCl (Thomas, *C. J.* 33, 27). Na_2HPO_4Aq absorbs CO_2 (Pagenstecher, *J. B.* 21, 124; Liebig, *A.* 64, 349; 79, 112; Heidenhain a. L. Meyer, *A. Suppl.* 2, 157; Marchand, *J. pr.* 37, 321). The solution decomposes NH_4Cl (Rose, *Gm.-K.* 2, 166); boiled with S forms Na_3PO_4Aq with $Na_2S_2O_3$Aq and Na polysulphides (Filhol a. Senderens, *C. R.* 94, 649; 95, 343; 96, 1057). For remarks on character of reactions of Na_2HPO_4Aq with solutions of metallic salts *v.* Joly, *C. R.* 103, 1129.

Trisodium diphosphate $Na_3H_3P_2O_8.xH_2O$; by exactly neutralising H_3PO_4Aq by NaOHAq, and evaporating *in vacuo* (Filhol a. Senderens, *l.c.*).

Sodium dihydrogen phosphate $NaH_2PO_4.H_2O$; by adding H_3PO_4 to solution of $Na_3H_3P_2O_8$ till $BaCl_2$Aq is no longer ppd. (Mitscherlich, Berzelius, *Gm.-K.* 2, 167). A salt with $4H_2O$ was obtained by Joly a. Duffet (*C. R.* 102, 1391) by cooling a very conc. solution.

Double salts. 1. *Sodium ammonium hydrogen orthophosphate* $Na(NH_4)HPO_4.4H_2O$ (*Microcosmic salt*). Occurs in guano. Obtained by dissolving 5 pts. $Na_2HPO_4.12H_2O$ and 2 pts. $(NH_4)_2HPO_4$ in water, adding a little NH_3Aq, and allowing to crystallise in the cold (Berzelius). Large, clear, monoclinic crystals; S.G. 1·554 (Schiff); very soluble water, solution loses NH_3. The solid effloresces in air, losing all NH_3 and $4H_2O$, and leaving NaH_2PO_4; when strongly heated leaves $Na_6(PO_3)_6$. For double salts formed by fusing with metallic oxides *v.* Wallroth, *B.* 16, 3059.—2. $NaKHPO_4.7H_2O$ (Mitscherlich, Liebig, Schiff, *Gm.-K.* 2, 167). – **3.** $Na(NH_4)_2PO_4.4H_2O$ (*v. Gm.-K.* 2, 220). – **4.** $Na_2(NH_4)PO_4.12H_2O$ *(Herzfeld a. Feuerlein, Fr. 1881. 191). — 5.* $Na_4K_3H_5(PO_4)_4.22H_2O$, and $Na_3(NH_4)_3H_6(PO_4)_4.3H_2O$ (Filhol a. Senderens, *C. R.* 94, 649; 95, 343; 96, 1057).— 6. $2Na_3PO_4.NaF.xH_2O$; $x=19$ and 22 (Baumgarten, *J.* 1865. 219; Thorpe, *C. J.* [2] 10, 660).

Strontium orthophosphates. *Normal salt* $Sr_3P_2O_8$, is ppd. by adding Na_3PO_4Aq or Na_2HPO_4Aq + NH_3Aq to excess of $SrCl_2$Aq; also by adding cold ammoniacal solution of 90 pts. $Na_2HPO_4.12H_2O$ to 100 pts. $SrCl_2$ in Aq (Barthe, *C. R.* 114, 1267). By pouring $SrCl_2$Aq into Na_3PO_4Aq at c. 10° gelatinous $Sr_3P_2O_8$ is formed, but rapidly changes to crystalline $SrNaPO_4.9H_2O$ (Joly, *C. R.* 104, 1702.)—*Acid salt* $SrHPO_4$; by adding Na_2HPO_4Aq to $SrCl_2$Aq (Skey, *C. N.* 22, 61; Berzelius, Brett, Wittstein, *Gm.-K.* 2, 324; Malaguti, *A. Ch.* [3] 51, 346; Barthe, *l.c.*). Barthe (*l.c.*) describes another *acid salt*, $SrH_4P_2O_8.2H_2O$.

Double salts. 1. $3Sr_3P_2O_8.SrCl_2$ (Deville a. Caron, *A. Ch.* [3] 67, 452).—2. $SrKPO_4$ (Rose, Weber, *Gm.-K.* 2, 324).—3. $SrNaPO_4.9H_2O$ (R. W., *l.c.*; Joly, *C. R.* 104, 905, 1702).

Thallium orthophosphates. *Normal thallous orthophosphate* Tl_3PO_4; by adding H_3PO_4Aq and NH_3Aq to $TlNO_3$Aq, or mixing Tl_2SO_4Aq and Na_2HPO_4Aq with a little NH_3Aq (Crookes, *C. N.* 3, 193, 303; 7, 290; 8, 159; Lamy, *Bl.* [2] 4, 193). While silky mass, or needles; insoluble alcohol, easily soluble NH_4 salts (Carstanjen, *J. pr.* 102, 65, 129). *Acid salts.*—TlH_2PO_4 and $Tl_2HPO_4.xH_2O$ (Lamy, *l.c.*); according to Rammelsberg (*B.* 15, 283) the second of these does not exist. *Normal thallic orthophosphate* $TlPO_4.2H_2O$, by adding H_3PO_4Aq to $Tl(NO_3)_3$Aq (Willm, *Bl.* [2] 2, 89; 5, 354; Strecker, *J. pr.* 102, 65, 129).

Thorium orthophosphates. Various *double salts* of Th and K, and Th and Na, are described by Troost and Ouvrard (*C. R.* 102, 1422; 105, 30).

Tin orthophosphates. The compositions of the *stannous salt*, obtained by adding Na_2HPO_4Aq to $SnCl_2$ in dilute acetic acid, and the *stannic salt*, by digesting SnO_2 with H_3PO_4Aq, are somewhat doubtful (*v.* Lenssen, *A.* 114, 113; Reynoso, *J. pr.* 54, 261; Reissig, *A.* 98, 339; Girard, *C. R.* 54, 468). Ouvrard (*C. R.* 111, 177) describes various double Sn-K and Sn-Na phosphates.

Titanium orthophosphates. Various *double salts* of Ti and K, and Ti and Na, are described by Ouvrard (*C. R.* 111, 177).

Uranium orthophosphates. For *double* U-K and U-Na *salts*, *v.* Ouvrard (*C. R.* 110, 1333). Johnson (*B.* 22, 976) describes a salt $UO_3.2P_2O_5$.

Zinc orthophosphates. *Normal salt* $Zn_3P_2O_8.4H_2O$; by ppg. solution of a Zn salt by Na_2HPO_4Aq; pp. is gelatinous, but becomes crystalline. Insoluble water, easily soluble in acids, NH_3Aq, and NH_4 salts (*v.* Mitscherlich, *Gm.-K.* 3, 16; Schindler, *Mag. Pharm.* 26, 62; Debray, *Bl.* [2] 2, 14; Heintz, *A.* 143, 356; Graham, *A.* 29, 23). The *acid salt* $ZnH_4P_2O_8.2H_2O$ is obtained in large, triclinic crystals by dissolving ZnO in H_3PO_4Aq (Demel, *B.* 11, 1171).

Double salts. 1. With NH_4, *v.* Debray (*C. R.* 59, 40), Bette (*A.* 15, 129), Heintz (*A.* 143, 156), Schweikert (*A.* 145, 57), Rother (*A.* 143, 356).—2. *With Na, v. Scheffer (A. 145, 53), Ouvrard (C. R. 106, 1729).*—3. With K, *v.* Ouvrard (*l.c.*).

Zirconium orthophosphates. For *double salts* with K and Na, *v.* Ouvrard, *C. R.* 102, 1422; 105, 30.

PYROPHOSPHATES. *Salts derived from* $H_4P_2O_7$. (For *Thiopyrophosphates v.* PHOSPHORIC SULPHIDE, *Reactions*, No. 7, p. 147; and for *Selenopyrophosphates*, *v.* PHOSPHORIC SELENIDE, p. 145.)

Aluminium pyrophosphate $Al_4(P_2O_7)_3$. White amorphous pp. by adding $AlCl_3$Aq to $Na_4P_2O_7$Aq; soluble NH_3Aq, $Na_4P_2O_7$Aq, and mineral acids (Schwarzenberg, *A.* 65, 147; Rose, *A.* 76, 16; Wittstein, *Repert.* 63, 224). Forms a *double salt* with Na (Persoz, *A.* 65, 170; Pahl, *Bl.* [2] 22, 122).

Ammonium pyrophosphates. *Normal salt* $(NH_4)_4P_2O_7$; by adding excess NH_3Aq to $H_4P_2O_7$Aq and recrystallising from alcohol. Solution boiled gives the *acid salt* $(NH_4)_2H_2P_2O_7$ (Schwarzenberg, *A.* 65, 141).

Barium pyrophosphate $Ba_2P_2O_7.xH_2O$. White amorphous solid; by adding $Na_4P_2O_7$Aq to $BaCl_2$Aq, or $H_4P_2O_7$Aq to BaOAq. Heated in

steam gives off PH_3; gives orthophosphate by heating with alkali carbonates (Hesse, *P.* 80, 71; Schwarzenberg, *l.c.*; Birnbaum, *Z.* [2] 7, 139; Struve, *J. pr.* 79, 348; Rose, *P.* 76, 20). Forms a *double salt* with Na (Baer, *P.* 75, 166).

Bismuth pyrophosphate $Bi_4(P_2O_7)_3$ (Chancel, *C. R.* 50, 416).

Cadmium pyrophosphate $Cd_2P_2O_7.2H_2O$ (at 100°) (Schwarzenberg, *A.* 65, 153).

Calcium pyrophosphates *Normal salt* $Ca_2P_2O_7.4H_2O$, by adding $Na_4P_2O_7Aq$ to $CaCl_2Aq$, or CaOAq to $H_4P_2O_7Aq$; sol. in much $Na_4P_2O_7Aq$. Amorphous, but crystallises from solution in acetic acid or SO_2Aq (Schwarzenberg, *A.* 65, 145; Rose, *P.* 76, 16, 20, 230). For action of heat, *v.* Baer (*P.* 75, 155). Decomposed by water at 280° to H_3PO_4Aq and $Ca_3P_2O_8$ (Reynoso, *C. R.* 34, 795). Partially decomposed by boiling with NaOHAq or fusing with alkali carbonate (Rose). The *acid salt* $CaH_2P_2O_7.2H_2O$ is said to be obtained by decomposing the normal salt by a little $H_2C_2O_4Aq$ (Pahl, *Bl.* [2] 22, 122). Von Knorre a. Oppelt (*B.* 21, 769) failed to obtain this salt, but prepared the salt $2CaH_2P_2O_7.Ca_2P_2O_7.6H_2O$ by adding $CaCl_2Aq$ to $Na_2H_2P_2O_7Aq$.

Double salt $CaNa_2P_2O_7.4H_2O$ (Baer, *P.* 75, 159).

Chromium pyrophosphate $Cr_4(P_2O_7)_3$. A reddish green pp. by adding $Na_4P_2O_7Aq$ to Cr alum solution; soluble $Na_4P_2O_7Aq$, KOHAq, SO_2Aq, and mineral acids (Schwarzenberg, *A.* 65, 149).

Cobalt pyrophosphates. Salts having the composition $Co_3P_4O_{13}$ and $Co_6P_{10}O_{31}$ are said to be formed by strongly heating luteo-cobalt phosphate (Braun, *Fr.* 3, 468; *Gm.-K.* 3, 463).

Copper pyrophosphates. The *normal salt* $Cu_2P_2O_7.2H_2O$, by adding $Na_4P_2O_7Aq$ (not excess) to Cu salt solutions and drying at 100°; greenish-white amorphous pp., becoming crystalline by boiling in SO_2Aq; soluble $Na_4P_2O_7Aq$, NH_3Aq, and mineral acids (Schwarzenberg, *A.* 65, 156; Stromeyer a. Gladstone, *Gm.-K.* 3, 615). Forms *double salts* with NH_4, K, and Na (*v.* Schwarzenberg, *l.c.*; Schiff, *A.* 123, 1; Persoz, *A. Ch.* [3] 20, 315; Fletimann a. Henneberg, *A.* 65, 387).

Iron pyrophosphates. The *ferrous salt* is obtained by ppg. $FeSO_4Aq$ by $Na_4P_2O_7Aq$; composition not decided (*v.* Schwarzenberg, *A.* 65, 153; Struve, *J. pr.* 79, 318). The *ferric salt* $Fe_4(P_2O_7)_3.9H_2O$ is a yellowish pp., formed by adding neutral $FeCl_3Aq$ to $Na_4P_2O_7Aq$ (acidified $FeCl_3Aq$ gives $FePO_4$; Schwarzenberg). Gladstone (*C. J.* [2] 5, 435) obtained an allotropic form by heating the ordinary salt in dilute H_2SO_4Aq.

Double salts, with Na (Gladstone, *l.c.*; Persoz, *A. Ch.* [3] 20, 315; Fleitmann a. Henneberg, *A.* 65, 390; Rieckher, *N. J. P.* 23, 1; Milck, *J.* 1865. 263).

Lead pyrophosphate $Pb_2P_2O_7$. A white amorphous powder; by ppg. $Pb(NO_3)_2Aq$ by $Na_4P_2O_7Aq$. Obtained in colourless, transparent, rhombic prisms by dissolving PbO in molten KPO_3 (Ouvrard, *C. R.* 110, 1333). Soluble excess of $Na_4P_2O_7Aq$, insoluble acetic acid or NH_3Aq; decomposed by boiling water (Stromeyer, Schwarzenberg, *Gm.-K.* 3, 121; Gerhardt, *A. Ch.* [3] 22, 5[illegible]6). Forms a *double salt* with Na (Gerhardt, *l.c.*; Ouvrard, *l.c.*).

Lithium pyrophosphate $Li_4P_2O_7.2H_2O$; by adding $Na_4P_2O_7Aq$ to LiClAq, dissolving in acetic acid, and ppg. by alcohol (Rammelsberg, *B. B.* 1883. 18; Merling, *J.* 1879. 1043). A *double salt*, $Li_3NaP_2O_7$, is formed in prismatic crystals by dissolving Li_2CO_3 in molten $NaPO_3$ (Ouvrard, *C. R.* 110, 1333).

Magnesium pyrophosphates. The *normal salt* $Mg_2P_2O_7.3H_2O$ is formed by adding $MgSO_4Aq$ to $Na_4P_2O_7Aq$ (Rose, *P.* 76, 16, 20), or by dissolving MgO in $Na_2H_2P_2O_7Aq$ and heating (Schwarzenberg, *Gm.-K.* 2, 448). Pp. becomes crystalline by remaining under liquid from which it has been ppd. (Popp, *Z.* [2] 6, 305), also by boiling with SO_2Aq (Schwarzenberg, *l.c.*). The salt is obtained, without H_2O, by strongly heating $MgNH_4PO_4$. Loses $3H_2O$ at 100°; fused with soda or heated with conc. H_2SO_4 gives $Mg_3P_2O_8$ (Rose; Weber, *P.* 73, 137). Easily soluble HClAq and HNO_3Aq; ppd. incompletely by NH_3Aq (Fresenius; Weber). An *acid salt*, $MgH_2P_2O_7$, combined with NO_2, is said to be formed by evaporating to dryness with HNO_3Aq (Luck, *Fr.* 13, 255; Campbell, *P. M.* [4] 21, 380). Forms a *double salt* with Na (Persoz, *A.* 65, 169; Schwarzenberg, *A.* 65, 146; Beer, *P.* 75, 168).

Manganese pyrophosphates. The *normal manganous salt* $Mn_2P_2O_7.3H_2O$ is a white amorphous powder; by ppg. a salt of Mn by $Na_4P_2O_7Aq$ (Schwarzenberg, *A.* 65, 133). Soluble $Na_4P_2O_7Aq$ (Pahl, *Bl.* [2] 22, 122). Loses one H_2O at 120° (S., *l.c.*). The salt without H_2O is formed by strongly heating the hydrated salt, or $MnHPO_4.3H_2O$, or $MnNH_4PO_4.H_2O$ (S., *l.c.*; Heintz, &c., *Gm.-K.* 2, 475); white powder, S.G. 3·5847 at 20° (Lewis, *Am. S.* [3] 14, 281); heated to whiteness in H gives $Mn_3P_2O_8$; reduced by charcoal to Mn phosphide (Struve, *J.* 1860. 78). The *acid salt* $MnH_2P_2O_7.4H_2O$ is said to be formed by action of oxalic acid on the normal salt (Pahl, *l.c.*). Various *double salts* are described with K (Pahl, *l.c.*; Schjerning, *J. pr.* [2] 45, 515); with Na (Pahl, Rose; Christensen, *J. pr.* [2] 34, 41); with Na and NH_4 (*v.* Otto, *J. pr.* 2, 418). The *acid manganic salt* $MnHP_2O_7$ is said to be formed by heating $MnPO_4$ with H_3PO_4Aq to 170°-190° (Christensen, *J. pr.* [2] 28, 1).

Mercury pyrophosphates. The *normal mercurous salt* $Hg_4P_2O_7.H_2O$ is a heavy white powder obtained by adding $Na_4P_2O_7Aq$ to $HgNO_3Aq$ (Rose, *Gm.-K.* 3, 754; Schwarzenberg, *A.* 65, 133). The *normal mercuric salt*, $Hg_2P_2O_7$, is obtained by adding $Na_4P_2O_7Aq$ to $Hg(NO_3)_2Aq$ (S., *l.c.*; Reynoso, *C. R.* 34, 795).

Nickel pyrophosphate $Ni_2P_2O_7$. A green pp. by adding $Na_4P_2O_7Aq$ to $NiSO_4Aq$; soluble excess $Na_4P_2O_7Aq$, NH_3Aq, and acids; obtained crystalline by boiling with SO_2Aq; decomposed by water at 280°-300° (S., *l.c.*; Reynoso, *l.c.*).

Potassium pyrophosphates. The *normal salt*, $K_4P_2O_7.xH_2O$, is obtained by strongly heating K_2HPO_4; also formed by reaction of $POCl_3$ with KOHAq (Gladstone, *C. J.* [2] 5, 435). Loses one H_2O at 100°, and is dehydrated at 300°. Solution in water does not change to K_2HPO_4 on boiling (Schwarzenberg), nor on evaporation (Gladstone), but change is effected by heating to 280° (Reynoso, *C. R.* 34, 795); boiling with KOHAq produces the ortho- salt. The *acid salt*, $K_2H_2P_2O_7$, *is obtained by treating the normal with acetic* acid and alcohol, and evaporating over H_2SO_4 (Schwarzenberg, *A.* 65, 137). Forms a *double salt* with $2K_2(NH_4)HP_2O_7.H_2O$ (S., *l.c.*); also with $Cr_2H_4(P_2O_7)_2$ (Schjerning, *J. pr.* [2] 45, 515).

Silver pyrophosphates. *Normal salt*, $Ag_4P_2O_7$; a white pp. from $AgNO_3Aq$ and $Na_4P_2O_7Aq$ (Clark, Stromeyer, *Gm.-K.* 3, 919). S.G. 5·306 at 7·5°; soluble NH_3Aq, reppd. by HNO_3Aq; boiled with Na_2HPO_4Aq gives Ag_3PO_4. Heated with H_3PO_4Aq at 180° gives the *acid salt* $Ag_2H_2P_2O_7$ (Hurtzig a. Geuther, *A.* 111, 160).

Sodium pyrophosphates. The *normal salt*, $Na_4P_2O_7$, is formed by strongly heating Na_2HPO_4; a glass-like solid, becoming opaque on cooling (Clark, *N. Ed. P. J.* 7, 298); gives Na_3PO_4 and PH_3 when heated in H (Struve, *J. pr.* 79, 350); heated with NH_4Cl gives NaCl, $NaPO_3$, and PCl_3 (Rose). The hydrated salt, $Na_4P_2O_7.10H_2O$, crystallises from $Na_4P_2O_7Aq$ (Clark, *l.c.*; von Blücher, *P.* 50, 542) in monoclinic crystals (Rammelsberg; Haidinger, *P.* 16, 510; Handl, *W. A. B.* 32, 250; Schacchi, *P.* 109, 365; Duffet, *C. R.* 102, 1327). Crystallises unchanged from Aq with NH_3 or NH_4Cl added. Solution boiled with acids gives Na_3PO_4Aq. Poggiale (*J. Ph.* [3] 44, 273) gives solubility; 100 parts water dissolve—

	$Na_4P_2O_7$	$Na_4P_2O_7.10H_2O$

100	40·26	93·11

The *acid salt* $Na_2H_2P_2O_7$; by heating NaH_2PO_4 to 190°–204° (Graham, *Gm.-K.* 2, 169), or by addition of alcohol to an acetic acid solution of $Na_4P_2O_7$ (Schwarzenberg, *A.* 65, 139). Crystallises from aqueous solution with $6H_2O$ (Bayer, *J. pr.* 106, 501; Rammelsberg, *B.* 16, 21; Duffet, *C. R.* 102, 1327). When strongly heated gives $Na_4H_2P_4O_{13}$ (Fleitmann a. Henneberg, *A.* 65, 328).

Double salts.—1. $Na_2(NH_4)_2P_2O_7.xH_2O$, $x=5$ or 6 (Schwarzenberg, *A.* 65, 140, 142; Rammelsberg). — 2. $Na_2K_2P_2O_7.12H_2O$, and $Na_4P_2O_7.Na_2H_2P_2O_7.2H_2O$ (S., *l.c.*; R., *l.c.*). Wallroth (*Bl.* [2] 39, 316) has described double salts with pyrophosphates of Al, Be, Bi, Cd, Ca, Ce, Cr, Co, Cu, Di, Er, La, Mn, Mg, Ni, Th, Yb, Y, Zn, and Zr. For double salts with pyrophosphates of Sn and Ti *v.* Wunder, *J.* 1870. 359; 1871. 323. $Na_4P_2O_7$ seems to combine with B_2O_3 by fusing $Na_4P_2O_7$ with boric acid (Prinvault, *C. R.* 74, 1219).

Strontium pyrophosphate, $Sr_2P_2O_7$. A crystalline powder; from $Sr(NO_3)_2Aq$ and $Na_4P_2O_7Aq$; also by heating $SrHPO_4$ (S., *l.c.*). Forms *acid salts* (von Knorre a. Oppelt, *B.* 21, 769); also a *double salt* with Na (Baer, *P.* 75, 166).

Thallium pyrophosphates. *Normal thallous salt*, $Tl_4P_2O_7$; by heating Tl_2HPO_4 (Descloizeaux, *A. Ch.* [4] 17, 329). S.G. 6·786. Crystallises from aqueous solution with $2H_2O$ (D., *l.c.*). The *acid salt* $Tl_2H_2P_2O_7.H_2O$ is formed by heating TlH_2PO_4 to 250°–275° (Lamy, Rammelsberg, *Gm.-K.* 3, 177).

Thorium pyrophosphates. *Double salts* with K and Na are described by Ouvrard (*C. R.* 105, 30).

Uranium pyrophosphates. *Double salts* with K and Na are described by Ouvrard (*C. R.* 110, 1333).

Yttrium pyrophosphate. Johnson describes $Y_4(P_2O_7)_3$, formed by heating Y_23SO_4 with HPO_3 to 316° (*B.* 22, 976).

Zinc pyrophosphate, $Zn_2P_2O_7$. By ppg. Zn salts by $Na_4P_2O_7$ (Stromeyer, *Gm.-K.* 2, 832; Gladstone, *ibid.* 3, 16; Schwarzenberg). Forms a *double salt* with NH_4 (Bette, *A.* 15, 129).

Zirconium pyrophosphates. *Double salts* with K and Na are described by Ouvrard (*C. R.* 105, 30).

METAPHOSPHATES. *Salts derived from* HPO_3. The general methods of preparation, properties, and reactions of the metaphosphates are described at the beginning of this article (p. 106); the divisions into *mono-*, *di-*, *tri-*, *tetra-*, and *hexa- metaphosphates*, with the processes by which typical salts of each division are prepared, have also been described already (p. 107). It will suffice here to enumerate the salts, with an indication in each case to which division the salt is assigned by Maddrell, Fleitmann a. Henneberg (*cf.* Tammann's results regarding Na, di-, and tri- metaphosphates p. 107). T.'s paper in *J. pr.* [2] 45, 417 should also be consulted.

Aluminium dimetaphosphate, $Al_2P_6O_{18}$. By dissolving $Al_2O_3.xH_2O$ in H_3PO_4Aq, evaporating, and heating to 316° (Maddrell, *C. S. Mem.* 3, 373; Johnson, *B.* 22, 976). For *hexa- salt v.* T., *J. pr.* [2] 45, 417.

Ammonium metaphosphates. $(NH_4)_2P_2O_6$, from Cu salt by $(NH_4)_2SAq$; at 200°–250° becomes *mono- salt* $(NH_4)PO_3$ (Fleitmann, *A.* 72, 236). For *deca-* and *penta- salts* v. T., *l.c.*

Barium metaphosphates. (1) ? *Mono- salt* BaP_2O_6; by heating $BaCO_3$ with H_3PO_4 to 316° (M., *l.c.*; F., *l.c.*; Rose, *P.* 76, 5; Birnbaum, *Z.* [2] 7, 139). (2) *Di- salt*, $Ba_2P_4O_{12}.xH_2O$; from Na or NH_4 salt and $BaCl_2Aq$ (F., *l.c.*). (3) *Tri- salt*, $Ba_3P_6O_{18}.xH_2O$; from Na salt and $BaCl_2Aq$ (F. a. Henneberg, *A.* 65, 313). (4) *Hexa- salt*; from Na salt and $BaCl_2Aq$ (Rose; Graham, *P.* 32, 68).

Bismuth metaphosphate. ? *Tetra- salt*; by fusing H_3PO_4 with $Bi_2O_3.xH_2O$ (F., *l.c.*); HPO_3Aq, $Bi3NO_3$ solution and NH_3Aq give a pp. (Persoz, *Gm.-K.* 2, 832).

Cadmium metaphosphate. ? *Tetra- salt* (F., *l.c.*; Persoz, *Gm.-K.* 3, 54). *Double salts* with Na and K (Ouvrard, *C. R.* 106, 1729).

Calcium metaphosphates. A salt is obtained by heating $CaHPO_4$; for action of HPO_3 on $CaCO_3$ *v.* Rose (*P.* 76, 5), Liebig (*A.* 11, 262). *Di- salt*, $Ca_2P_4O_{12}.xH_2O$; from Na salt and $CaCl_2Aq$ (M., *l.c.*; F., *l.c.*). *Double salts.*— $CaAm_2P_4O_{12}.2H_2O$ (F., *l.c.*); $CaNaP_3O_9$ (F. a. H., *l.c.*).

Chromium dimetaphosphate, $Cr_2P_6O_{18}$. By heating CrO_3H_3 with H_3PO_4 to 316° (M., *l.c.*; Hautefeuille a. Margottet, *C. R.* 96, 849, 1042; Johnson, *B.* 22, 976).

Cobalt metaphosphates. ? *Mono- salt* CoP_2O_6; by evaporating $CoSO_4$ with H_3PO_4Aq, and heating to 316° (M., *l.c.*; H. a. M., *l.c.*). *Di- salt* $Co_2P_4O_{12}$; by heating roseo-cobaltic phosphate (Braun, *Ammon. Kobaltverbindungen* [Göttingen, 1862]). ? *Hexa- salt* $Co_6P_{12}O_{36}$; by $CoCl_2$Aq and the Na salt (Rose). *Okto- salt* (T., *l.c.*). *Double salt* with Na (M., *l.c.*).

Copper metaphosphates. *Di- salt* $Cu_2P_4O_{12}$; by heating CuO or $Cu(NO_3)_2$ with H_3PO_4 to 316° (M., *l.c.*; F., *l.c.*); obtained with $8H_2O$ by evaporating $CuSO_4$Aq mixed with $Na_2P_2O_6$ (F. *l.c.*). ? *Hexa- salt*; by ppg. $CuCl_2$Aq (*not* $CuSO_4$Aq) by the Na salt (Rose). *Double salts* with NH_4 and Na (F., *l.c.*; T., *l.c.*).

Iron metaphosphate. *Di-ferric salt* $Fe_2P_6O_{18}$; by heating $FeCl_3$ with H_3PO_4 to 316° (M., *l.c.*; H. a. M., *l.c.*; Johnson, *B.* 22, 976).

Lithium hexametaphosphate. A *double salt* $Li_2Na_4P_6O_{18}$, is described by Tammann (*l.c.*).

Lead metaphosphates. *Di- salt* $Pb_2P_4O_{12}$; from $Pb(NO_3)_2$Aq and the Na salt; also by heating H_3PO_4 and PbO (F., *l.c.*). *Tri- salt* $Pb_3P_6O_{18}$; from the Na salt and $Pb(NO_3)_2$Aq (F. a. H., *l.c.*). *Deka-salt*, T. (*l.c.*). *Double salt* $PbAm_2P_4O_{12}$ (F., *l.c.*).

Magnesium metaphosphates. ? *Mono- salt* MgP_2O_6, by heating MgO with H_3PO_4 (M., *l.c.*). *Di- salt* $Mg_2P_4O_{12}.xH_2O$; and *tri- salt* $Mg_3P_6O_{18}.xH_2O$; from the corresponding Na salt and $MgCl_2$Aq (F., *l.c.*). *Hexa- salt* $Mg_6P_{12}O_{36}$ (Graham, *Gm.-K.* 2, 214). *Double salts*, with NH_4 and Na, *v.* F. (*l.c.*); F. a. H. (*l.c.*); M. (*l.c.*); Graham (*l.c.*); Ouvrard (*C. R.* 106, 1729); Tammann (*l.c.*).

Manganese metaphosphates. *Di- salt* $Mn_2P_4O_{12}$; by heating a Mn salt with H_3PO_4 to 316° (M., *l.c.*; F., *l.c.*); with $8H_2O$ by ppg. $(NH_4)_2P_2O_6$Aq by excess of $MnCl_2$Aq (F., *l.c.*). *Tri- salt* $Mn_3P_6O_{18}.11H_2O$; from $MnCl_2$Aq (*not* $MnSO_4$) and $Na_3P_3O_9$. *Hexa- salt* $Mn_6P_{12}O_{36}$; by using $Na_6P_6O_{18}$ (Otto, Rose, *Gm.-K.* 2, 490; Braun, *l.c.*). *Deka- salt* $Mn_{10}P_{20}O_{60}$ (Tammann, *J. pr.* [2] 45, 417). *Double salts*, with NH_4 and Na (*v.* F., *l.c.*; Rose, *l.c.*; T., *l.c.*).

Mercury metaphosphates. White pps. are formed by adding Na tri- and hexa- metaphosphate to $Hg(NO_3)_2$Aq (F. a. H., *l.c.*; Rose, *Gm.-K.* 2, 754).

Nickel metaphosphates. *Di- salt* $Ni_2P_4O_{12}$; by heating Ni_2O_3 with H_3PO_4 to 316° (M., *l.c.*; H. a. M., *l.c.*). *Hexa- salt* $Ni_6P_{12}O_{36}$; by adding $NiCl_2$Aq to $Na_6P_6O_{18}$ (Rose). *Double salt* with Na (M., *l.c.*).

Potassium metaphosphates. *Mono- salt* KPO_3; by heating KH_2PO_4 to full redness (M., *l.c.*; Graham, Darracq, *Gm.-K.* 2, 32). S.G. 2·2639 at 14·5° (Clarke, *Am. S.* [3] 14, 281). *Di- salt* $K_2P_2O_6$; by treating the Cu salt with K_2SAq (F., *l.c.*). *Hexa- salt* $K_6P_6O_{18}$ (T., *l.c.*). *Double salt* with NH_4 (F., *l.c.*). *Compound with* B_2O_3 (Prinvault, *C. R.* 74, 1249).

Silver metaphosphates. *Di- salt* $Ag_2P_2O_6$; and *tri- salt* $Ag_3P_3O_9$; from $AgNO_3$Aq and the corresponding Na salts (F., *l.c.*; F. a. H., *l.c.*). *Hexa- salt* $Ag_6P_6O_{18}$; from $AgNO_3$ heated with H_3PO_4 to 316°, or by adding $Na_6P_6O_{18}$Aq to $AgNO_3$Aq (Graham; F., *l.c.*; T., *l.c.*; Rose, Berzelius). *Double salts* with Al, Cr, and Fe (H. a. M., *l.c.*).

Sodium metaphosphates. For conditions of formation and general reactions *v.* p. 106. The following salts have been described: *Mono- salt* $NaPO_3$ (F., *l.c.*; M., *l.c.*; F. a. H., *l.c.*; Graham, *Gm.-K.* 2, 170; Jamieson, *A.* 59, 350; Müller, *P.* 127, 428); *di- salt* $Na_2P_2O_6.2H_2O$ (F., *l.c.*); *tri- salt* $Na_3P_3O_9.6H_2O$ (F. a. H., *l.c.*); *tetra- salt* $Na_4P_4O_{12}$ (F., *l.c.*); *hexa- salt* $Na_6P_6O_{18}$ (F., *l.c.*; T., *l.c.*; G., *l.c.*). For *double salts* with Na and NH_4, *v.* F. (*l.c.*).

Strontium metaphosphates. ? *Mono- salt* SrP_2O_6; by heating $SrCO_3$ with H_3PO_4 (M., *l.c.*; *cf.* Rose, *P.* 76, 8; Scheerer, *J. pr.* 75, 113). For a *deka- salt*, *v.* T. (*l.c.*).

Thallium metaphosphate. $TlPO_3$ said to exist in two forms, one insoluble in water (? di-salt), and the other soluble (Lamy, *Gm.-K.* 2, 177).

Thorium metaphosphate ThP_4O_{12} (? di- salt, $Th_2P_8O_{24}$); by heating $Th(SO_4)_2$ with H_3PO_4 to redness (Johnson, *B.* 22, 976). For *double salts* with K and Na, *v.* Troost a. Ouvrard (*C. R.* 105, 30).

Uranium metaphosphate. *Di- salt* $U_2P_8O_{18}$ (H. a. M., *l.c.*).

Zinc metaphosphates. *Di- salt* $Zn_2P_4O_{12}$; by heating ZnO with H_3PO_4 to 350° (F., *l.c.*); with $4H_2O$ by adding $ZnCl_2$Aq to $(NH_4)_2P_2O_6$Aq. For *double salts* with NH_4 and Na, *v.* F. a. H. (*l.c.*); Bette (*A.* 15, 129).

TETRAPHOSPHATES and DEKAPHOSPHATES. *Salts of the hypothetical acids* $H_6P_4O_{13}$ and $H_{12}P_{10}O_{31}$ (*v.* pp. 106, 107).

Barium tetraphosphate $Ba_3P_4O_{13}$. A heavy crystalline powder; by fusing $Na_6P_4O_{13}$ with $BaCl_2$ (F. a. H., *A.* 65, 313).

Magnesium tetraphosphate $Mg_3P_4O_{13}$. Prepared similarly to the Ba salt (F. a. H., *l.c.*).

Silver tetraphosphate $Ag_6P_4O_{13}$. From the Na salt and $AgNO_3$Aq (Berzelius, *P.* 19, 331).

Sodium tetraphosphate $Na_6P_4O_{13}$. By fusing $Na_6P_6O_{18}$ with $Na_4P_2O_7$ or Na_3PO_4 (F. a. H., *l.c.*; Uelsmann, *A.* 118, 101).

Silver dekaphosphate $Ag_{12}P_{10}O_{31}$. From the Na salt and $AgNO_3$Aq (F. a. H., *l.c.*; U., *l.c.*).

Sodium dekaphosphate $Na_{12}P_{10}O_{31}$. A glassy mass; by fusing $Na_6P_6O_{18}$ and $Na_4P_2O_7$ (F. a. H., *l.c.*).

M. M. P. M.

PHOSPHENYL CHLORIDE *v.* PHENYL-*di-chloro*-PHOSPHINE.

PHOSPHENYLIC ACID *v.* PHENYL PHOSPHITES.

PHOSPHENYLOUS ACID $C_6H_5PHO.OH$. *Benzene phosphinic acid.* [70°]. S. 7·23 in the cold; 211 at 100°. Formed by adding water to $C_6H_5PCl_2$, and boiling (Michaelis, *A.* 181, 303; *B.* 10, 816). Leaflets, v. sol. alcohol. Decomposed by heat into phenyl-phosphine, benzene, and HPO_3. PCl_5 forms $C_6H_5PCl_2$.—KA′ 2aq.—NH_4A'. BaA′₂ 4aq.—PbA′₂: amorphous pp.

Ethyl ether EtA′. Oil.

Di-ethyl ether $C_6H_5P(OEt)_2$ (235°). Formed from $C_6H_5PCl_2$ and NaOEt. Liquid with very powerful odour.

PHOSPHIDES. *Compounds of P with one other more positive element.* The chief phosphides are those of Al, Sb, As, Ba, Be, Bi, Cd, Ca, Cu, Cr, Au, H, Fe, Pb, Mg, Mn, Hg, Mo, Ni, K, Pt, Ag, Na, Th, Sn, Tl, W, Zn, Zr. (Phosphides of H are described as *Phosphorus hydrides* under PHOSPHORUS.) Many phosphides are formed by heating together P and the more positive element in an atmosphere of CO_2 or N; phosphides are also produced by heating P with several metallic oxides or with salts in solution; also by heating metals or their oxides in PH_3. Phosphides are generally brittle solids; many react with water or dilute acids, evolving P hydrides; some yield basic phosphates when heated in air. For descriptions of the different phosphides *v.* the individual elements.

M. M. P. M.

PHOSPHINE. PH_3 is sometimes known by this name, *v.* PHOSPHORUS, HYDRIDES OF, p. 135.

PHOSPHINES are the phosphorus analogues of amines, and result from the replacement of hydrogen in phosphuretted hydrogen by alkyl radicles. They may be classified, like the amines, into primary, secondary, and tertiary bases, and, in addition, quaternary compounds are known analogous to the salts of compound ammoniums.

Methods of preparation. 1. *Action of the haloid derivatives of hydrocarbon radicles on metallic phosphides.* It was by this reaction that Paul Thénard (*C. R.* 21, 141; 25, 892) discovered the first members of the phosphine group in 1843-47. He experimented with methyl chloride and calcium phosphide, and apparently isolated trimethyl-phosphine, $(CH_3)_2P_4$ as an inert solid, and a substance $(CH_3)_4P_2$ analogous to cacodyl as a spontaneously inflammable liquid, boiling at 250°, very explosive, poisonous, and unstable. Thénard recognised the relationship of trimethyl-phosphine to ammonia, and predicted the existence of the then undiscovered organic compounds of nitrogen and antimony.

In 1855 Hofmann a. Cahours (*T.* 1857; *A. Ch.* [3] 61, 5) investigated the action of methyl iodide on sodium phosphide, and obtained tetramethyl-phosphonium iodide in addition to trimethyl-phosphine and the phosphorised cacodyl of Thénard. They found that the method was dangerous, and furnished mixtures the separation of which presented enormous difficulties.

Berlé (*J. pr.* 66, 73) about the same time obtained very small quantities of triethyl-phosphine by the action at a very high temperature of ethyl iodide on sodium phosphide obtained by heating sodium and phosphorus together in rock oil.

Cahours in 1859 (*C. R.* 49, 87; *J.* 1859, 430) prepared tetrethyl-phosphonium iodide by the action of ethyl iodide on crystallised zinc phosphide (obtained by heating the metal in phosphorus vapour at 180°).

In 1882 Letts a. N. Collie (*Tr. E.* 30 pt. i. 181) investigated the action of benzyl chloride on sodium phosphide, and found that tetra-benzyl-phosphonium chloride was produced in abundance.

2. *Action of organo-metallic bodies on trichloride of phosphorus.* The action of zinc alkyls on phosphorus trichloride was first investigated by Hofmann a. Cahours (*A. Ch.* [3] 51), and was further studied by Hofmann (*A. Ch.* [3] 62; 63 · 64). By this method tertiary phosphines are exclusively formed: $3R_2Zn + 2PCl_3 = 2R_3P + 3ZnCl_2$. It is necessary to treat the product of the reaction with caustic potash, in order to decompose the compound of the phosphine with zinc chloride. By this reaction Hofmann a. Cahours obtained PMe_3 and PEt_3, and showed that they resemble the corresponding amines in many respects, especially in the readiness with which they combine with alkyl iodides to give quaternary compounds. On the other hand, they proved that, unlike the amines, tertiary phosphines readily combine with oxygen to give very stable compounds of the general formula R_3PO.

3. *Action of alcohols on phosphonium iodide; and 4. Action of alkyl iodides on phosphonium iodide and oxide of zinc* (Hofmann's methods). In the year 1871 Hofmann again took up the study of the phosphines (*B.* 4, 205), and by the action of alkyl iodides on phosphuretted hydrogen obtained not only tertiary and quaternary compounds, but also primary and secondary bases. Hofmann took advantage of the fact that phosphonium iodide when heated with alcohol yields phosphuretted hydrogen, ethyl iodide, and water. When phosphonium iodide (1 mol.) is heated with alcohol (3 mols.) for 8 hours at 180° the crystalline product is a mixture of PEt_3HI and PEt_4I, and, on addition of caustic soda, triethyl-phosphine separates as a clear liquid, while the solution gives, on evaporating, beautiful crystals of tetrethyl-phosphonium iodide. If the tubes are heated for four hours only, two layers of liquid are visible on cooling, and the tubes show great pressure when opened. It may be taken for granted, then, that the reaction occurs in two phases, in the first of which EtI is liberated, which then acts upon PH_3 in the same way as it acts on ammonia. Hofmann employed this method successfully in the methyl (*B.* 4, 209), ethyl (*B.* 4, 205), propyl (*B.* 6, 292), butyl (*B.* 6, 296), and amyl (*B.* 6, 297) series. Hofmann (*B.* 4, 372) endeavoured to prepare the primary and secondary bases according to the equations:

$$PH_4I + C_2H_6O = C_2H_5PH_2.HI + H_2O$$
$$PH_4I + 2C_2H_6O = (C_2H_5)_2PH.HI + 2H_2O,$$

by altering the proportions of phosphonium iodide and alcohol, but without success, the tertiary base being produced alone or mixed with the quaternary compound, while with the proportions required for the second equation the tubes invariably exploded.

In the meantime Drechsel a. Finkenstein (*B.* 4, 352) believed that they had succeeded in obtaining the primary bases by saturating EtI or MeI with PH_3, and allowing the solutions to remain for some time at the ordinary temperature, or by heating them at 100°, and also by heating an ethereal solution of ZnI_2 saturated with PH_3 together with MeI. Hofmann (*B.* 4, 372) repeated these experiments, and showed that only tertiary and quaternary derivatives were formed. The idea then occurred to him of heating the alkyl iodide with phosphonium iodide in presence of a metallic oxide, with the happiest results; for on heating a mixture of phosphonium iodide (2 mols.) with ethyl iodide (2 mols.) and zinc oxide (1 mol.) in sealed tubes at 150° for from six to eight hours, a complete reaction occurred, the tubes when cold containing a crystalline mass consisting exclusively of the hydriodates of the primary and secondary bases, the former being the chief product, while the latter was only formed in small quantities. The addition of water to the product of the reaction liberated the primary phosphine alone, which was distilled off in a hydrogen atmosphere, while the secondary phosphine was subsequently set at liberty by the action of an alkali. By means of this general method Hofmann prepared methyl (*B.* 4, 430), ethyl (*B.* 4, 605), propyl (*B.* 6, 292), butyl (*B.* 6, 296), amyl (*B.* 6, 297), and benzyl (*B.* 5, 100) phosphines.

4. *Michaelis's methods.* Hofmann's methods, although of excellent service for obtaining the phosphines of those radicles which form alcohols, could not be employed in the preparation of phosphines containing purely aromatic radicles (*B.* 5, 100). Michaelis, on the other hand, not only succeeded in obtaining all the phenyl-phosphines, but also in discovering a fairly general method for the production of primary phosphines. The substance forming the starting-point for the preparation of phosphines by these methods is trichloride of phosphorus. One atom of chlorine is first replaced in that body by one or other of the following processes:—

(A) The mixed vapours of a hydrocarbon and the trichloride are repeatedly passed through a red-hot tube. Thus when benzene is employed 'phosphenyl' chloride is obtained: $PCl_3 + C_6H_6 = (C_6H_5)PCl_2 + HCl$.

(B) A mercury alkyl is heated with the trichloride under pressure: $PCl_3 + (C_2H_5)_2Hg = (C_2H_5)PCl_2 + Hg(C_2H_5)Cl$.

(C) By digesting a hydrocarbon with the trichloride and aluminum chloride, the reaction being the same as (1). Other substances besides hydrocarbons yield substituted phosphorus chlorides when submitted to this reaction. Thus a mixture of acetone, PCl_3, and aluminium chloride react spontaneously, according to the equation:

$$2(CH_3)_2CO + PCl_3 = 2HCl + (CH_3.CO.CH_2)_2PCl.$$

By means of these different reactions Michaelis and his pupils have obtained a considerable number of substituted phosphorus chlorides, among which are: Phenyl phosphorus-chloride by methods 1, 2, and 3 (*B.* 6 [1873], 601; 8 [1875], 922; 12 [1879], 1009). Tolyl phosphorus-chloride by method 3 (*B.* 13, 653). Xylyl phosphorus-chloride by method 3 (*A.* 212, 203, 209). Ethyl phosphorus-chloride by method 2 (*B.* 13, 2174). Propyl phosphorus-chloride by method 2 (*B.* 13, 2174). Naphthyl phosphorus-chloride by method 2 (*B.* 9, 1051). Acetonyl phosphorus-chloride by method 3 (*B.* 17, 1273). The substituted chlorides resemble PCl_3 in properties. As a rule they are fuming liquids, combining readily with chlorine to give solid compounds analogous to pentachloride of phosphorus; treated with water, they yield phosphinous (phosphinic) acids. Thus phenyl phosphorus-chloride gives phenyl phosphinous (benzene phosphinic) acid: $(C_6H_5)PCl_2 + 2H_2O = (C_6H_5)PH_2O_2 + 2HCl$. The products of addition which they form with chlorine react with water to give phosphinic (phosphonic) acids: $(C_6H_5)PCl_4 + 3H_2O = (C_6H_5)PH_2O_3 + 4HCl$. Michaelis was unable to obtain more than mere traces of the primary phosphine by the action of nascent hydrogen on the substituted chlorides. When gaseous HI is passed into the chloride, chlorine is gradually displaced by iodine: $C_6H_5PCl_2 + 3HI = C_6H_5PI_2HI + 2HCl$. From this iodide Michaelis obtained phenyl-phosphine by the action of alcohol: $3C_6H_5PI_2HI + 9C_2H_6O = C_6H_5PH_2 + 2C_6H_5PO_3H_2 + 3H_2O + 9C_2H_5I$. In later experiments he employed a simpler method, namely the destructive distillation of the phosphinous (phosphinic) acid which, as already stated, is produced by the action of water or alcohol on the substituted chloride: $3C_6H_5PO_2H_2 = C_6H_5PH_2 + 2C_6H_5PO_3H_2$. From phenyl phosphorus chloride Michaelis obtained diphenyl-phosphine by the following reactions: (1) The chloride is digested with mercury diphenyl at 200°:

$$(C_6H_5)PCl_2 + Hg(C_6H_5)_2 = (C_6H_5)_2PCl + HgCl(C_6H_5)$$

(*B.* 8, 1304); or it is heated for some time at 280°, when the following reaction occurs:

$$2(C_6H_5)PCl_2 = (C_6H_5)_2PCl + PCl_3.$$

(2) Diphenyl phosphorus chloride when heated with water or dilute soda solution decomposes in the following manner: $2(C_6H_5)_2PCl + 2H_2O = (C_6H_5)_2PH + (C_6H_5)_2HPO_2 + 2HCl$ (Michaelis a. Gleichmann, *B.* 15, 801). He also obtained the tertiary base; at first by acting upon a mixture of phenyl-phosphorus chloride and bromo-benzene with sodium: $(C_6H_5)PCl_2 + 2C_6H_5Br + 3Na = 2NaCl + NaBr + (C_6H_5)_3P$, but later this method was modified in a remarkable way, by substituting for phenyl phosphorus chloride, phosphorus chloride alone, the reaction occurring quite easily and very energetically at ordinary temperatures according to the equation:

$$PCl_3 + 3(C_6H_5)Br + 6Na = 3NaCl + 3NaBr + (C_6H_5)_3P.$$

5. *Action of alcohols on a mixture of phosphorus and phosphorus iodide.* Letts a. Blake (*Tr. E.* pt. 2) have shown that very remarkable reactions occur when benzyl alcohol acts upon a mixture of phosphorus and phosphorus iodide (in the proportions employed for obtaining phosphonium iodide by the action of water), whereby a number of the phosphorus derivatives of benzyl are obtained. The action occurs spontaneously at ordinary temperatures, and, although its mechanism was found difficult to investigate, the following equations account for the formation of the different products:—

(1) $PI_2 + C_7H_7OH + H_2O = (C_7H_7)H_2PO_2 + HI + I$
(2) $PI_2 + C_7H_7OH + 2H_2O + I = (C_7H_7)H_2PO_3 + 3HI$
(3) $PI_2 + 2C_7H_7OH = (C_7H_7)_2HPO_2 + HI + I$
(4) $PI_2 + 3C_7H_7OH + HI = (C_7H_7)_3PO + 2H_2O + 3I$
(5) $PI_2 + 4C_7H_7OH + 4HI = (C_7H_7)_4PI + 4H_2O + 5I$
(6) $PI_2 + 2H_2O = H_3PO_2 + HI + I$
(7) $PI_2 + 4H_2O + 3I = H_3PO_4 + 5HI$
(8) $2HI + C_7H_7OH = C_7H_8 + H_2O + I_2$
(9) $P + I_2 = PI_2$

All the products indicated by the above equations were obtained in quantity, especially benzyl phosphinic acid, di-benzyl phosphinic acid, and tri-benzyl phosphine oxide, and the method is undoubtedly the easiest and best for the preparation of those substances. Whether other alcohols behave in a similar manner to benzyl alcohol with a mixture of phosphorus and its iodide has not yet been ascertained.

General properties of the primary phosphines. The following primary bases have been obtained:

Name	Condition	Boiling-point
Methyl-phosphine [1]	Gas	-14°
Ethyl " [2]	Liquid	25°
Iso-propyl " [3]	"	41°
Iso-butyl " [4]	"	62°
Iso-amyl " [5]	"	106°
n-Octyl " [6]	"	184°–187°
Phenyl " [7]	"	160°–161°
Benzyl " [8]	"	180°–183°
p-Tolyl " [9]	Solid at +4°	178°

[8] Hofmann, *B.* 5, 100; Letts a. Blake, *Tr. E.* 35 pt. 2.
[9] Michaelis a. Panek, *A.* 212, 233.

Most of the primary bases are liquids, insoluble in water, but soluble in ether. They fume in the air, and grow very hot, their vapour igniting spontaneously at times. The products of this oxidation appear to have been investigated only in a few cases, and chiefly in the aromatic series. Phenyl phosphine (Michaelis, *B.* 10, 807) and tolyl phosphine (Michaelis a. Panek, *A.* 212, 234) both absorb a molecule of oxygen, and are converted into phosphinous (phosphinic) acids, which are monobasic, and therefore probably have the constitution RPH(OH):O. These acids are readily decomposed by heat, giving the primary phosphine, and the corresponding phosphinic (phosphonic) acid $3RPH_2O_2 = RPH_2 + 2RPH_2O_3$, a reaction analogous to that which gives rise to phosphoretted hydrogen and phosphoric acid when hypophosphorous and phosphorous acids are heated. Letts and Blake (*Tr. E.* 35, pt. 2) find that benzyl phosphine yields a mixture of benzyl phosphinous (phosphinic) and benzyl phosphinic (phosphonic) acids with some phosphoric acid. Submitted to the action of strong nitric acid, many of the primary phosphines (and probably all) absorb three atoms of oxygen, and are converted into phosphinic (phosphonic) acids. This has been shown by Hofmann (*B.* 5, 110) to be the case in the methyl, ethyl, isopropyl, isobutyl, and isoamyl series.

The phosphinic acids are solid substances, which, with the lower members of the fatty series, can be distilled unchanged (Hofmann, *B.* 6, 303). But in some other instances a different reaction occurs: thus phenyl phosphinic (benzene phosphonic) acid when heated slowly to 200° gives a pyro-acid, while when rapidly heated to 250° it decomposes into benzene and metaphosphoric acid: $C_6H_5PH_2O_3 = C_6H_6 + HPO_3$. The phosphinic (phosphonic) acids are all dibasic, and no doubt have the structure $RPO(OH)_2$. All the primary phosphines have distinct alkaline properties. They combine readily with hydracids forming crystalline compounds, which can, as a rule, be volatilised (with dissociation more or less complete), and which resemble the compounds of phosphoretted hydrogen in being instantly decomposed by water with liberation of the phosphine. The hydrochlorides combine with chloride of platinum to give chloroplatinates. The salts of the primary bases with oxyacids have been scarcely at all investigated. The action of halogens on primary phosphines has not been sufficiently investigated. Methyl and ethyl phosphine take fire when they come in contact with chlorine or bromine (Hofmann, *B.* 4, 433, 609). Benzyl-phosphine yields with bromine a mixture of its own hydrobromide and substitution-products (Letts a. Blake, *Tr. E.* 35, pt. 2).

Sulphur acts on the primary bases. With the methyl and ethyl derivatives, compounds have been obtained but not investigated (Hofmann, *B.* 4, 433, 610). With phenyl phosphine sulphur acts slowly in the cold, rapidly at a high temperature (Michaelis, *B.* 10, 810). Two substances are produced, one, a thick liquid, soluble in ether, having the composition $(C_6H_5)PH_2S$, the other a crystalline product to which Michaelis assigns the formula $(C_6H_5P)_3S$. The first of these bodies decomposes when heated in the following manner:

$$2C_6H_5PH_2S = C_6H_5PS + C_6H_5PH_2 + H_2S.$$

When benzyl phosphine is warmed with sulphur the following reaction occurs (Letts a. Blake, *l.c.*):

$$2C_7H_7PH_2 + 6S = (C_7H_7)_2P_2S_3H_2 + H_2S$$

and the resulting pyro-benzyl-thiophosphinic acid when boiled with water is decomposed, yielding mono-thio-benzyl phosphinic acid:

$$(C_7H_7)_2P_2S_3H_2 + 4H_2O = 2C_7H_7PS(OH)_2 + 3H_2S.$$

In view of the analogies existing between nitrogen and phosphorus, considerable interest is attached to the action of carbonyl chloride and bisulphide of carbon on the primary phosphines. Bisulphide of carbon acts upon both methyl and ethyl phosphine (Hofmann, *B.* 4, 433, 610), but the products have not been investigated. Michaelis a. Dittler (*B.* 12, 338) have studied the action of both reagents on phenyl phosphine. When carbonyl chloride is passed slowly into that substance, an energetic reaction occurs in the following manner:

$$2COCl_2 + C_6H_5PH_2 = C_6H_5PCl_2 + 2CO + 2HCl.$$

Phenyl phosphine and bisulphide of carbon act upon each other when heated in a sealed tube at 150°, and sulphuretted hydrogen is liberated. The product of the reaction is a resinous body $(C_6H_5PHCS)_2S$, and the reaction itself proceeds according to the equation

$$2C_6H_5PH_2 + 2CS_2 = (C_6H_5PHCS)_2S + H_2S.$$

Michaelis a. Dittler were not successful in their attempts to prepare a phosphorised mustard oil from this compound.

They were equally unsuccessful in obtaining a phosphorised carbylamine by the action of chloroform and caustic potash on phenyl phosphine. It is true that a reaction occurs, but its course is completely different from that which takes place with an amine, viz.:

$$C_6H_5PH_2 + 4KHO + CHCl_3 = C_6H_5PHKO_2 + 3KCl + CH_3OH + H_2O.$$

It thus appears that, in their behaviour with carbonyl chloride and a mixture of caustic potash and chloroform, primary phosphines behave in an entirely different manner from the corresponding amines, though there is a certain degree of analogy as regards the action of both on bisulphide of carbon. This difference is no doubt due to the strong affinity of phosphorus for electronegative elements, such as the halogens, oxygen, and sulphur. Chloracetic and bromacetic acid react with benzyl phosphine, and chloroformic ether appears to form a product of addition (Letts a. Blake, *l.c.*). Probably other phosphines act in a similar manner with these reagents.

Primary phosphines readily combine with alkyl iodides to give hydriodides of secondary phosphines.

General properties of the secondary phosphines. The following secondary phosphines have been obtained:

Name	Condition	Boiling-point
Dimethyl phosphine [1]	Liquid	25°
Di-ethyl " [2]	"	85°
Di-isopropyl " [3]	"	118°
Di-isobutyl " [4]	"	153°
Di-isoamyl " [5]	"	210°–215°
Di-phenyl " [6]	"	280° (about)
Methyl-isopropyl " [7]	"	78°–80°
Iso-propyl, isobutyl " [8]	"	139°–140°
Di-benzyl " [9]	?	Decomposes when boiled

[9] Letts a. Blake, *l.c.*

All the secondary phosphines obtained as yet are liquids, having a powerful odour. They are insoluble in water, but soluble in ether &c.

They have as a rule a strong attraction for oxygen, fuming and growing hot on exposure to the air, and often inflaming spontaneously. In some cases they appear to have even a greater affinity for oxygen than the primary bases. This is so according to Hofmann with all the secondary phosphines of the fatty series which he obtained. But apparently it is not the case with diphenyl phosphine. The products of this spontaneous oxidation do not appear to have been examined except in the case of dibenzyl phosphine, which yields dibenzyl phosphinic (phosphonic) acid and possibly the oxide also $(C_7H_7)_2PO$ (Letts a. Blake, *l.c.*). But the products of their oxidation by nitric acid have been investigated, chiefly by Hofmann (*B.* 5, 104; 6, 303). These are in all cases phosphinic acids, R_2PHO_2, which are monobasic, and no doubt have the constitution $R_2P(OH)O$.

These acids are probably also produced when the chlorides R_2PCl are oxidised by nitric acid. Such is at least the case with $(C_6H_5)_2PCl$. Some of them can be distilled unchanged, *e.g.* dimethyl phosphinic acid; others, *e.g.* diphenyl and dibenzyl phosphinic acid, lose water, and give pyro-acids.

Secondary phosphines combine with acids, the resulting salts being far more stable than those of the primary bases. Thus in most cases they are not decomposed by water, though some are (*e.g.* salts of diphenyl phosphine). Comparatively little is known regarding secondary phosphines, and very few of their compounds have been investigated.

Sulphur acts upon them, and in the case of diethyl phosphine, according to A. W. v. Hofmann a. Mahla (*B.* 25, 2436), triethyl phosphine sulphide and diethyl dithiophosphinic acid. PEt_2SSH are formed, together with a third substance which probably has the composition $PSEt_2.S.S.S.PSEt_2$. Bisulphide of carbon also acts upon them, but the products do not appear to have been investigated. They readily combine with alkyl iodides, giving hydriodides of tertiary phosphines.

General properties of tertiary phosphines. The following tertiary bases have been obtained:

Name	Condition	Boiling-point
Trimethyl phosphine [1]	Liquid	40°–42°
Tri-ethyl " [2]	"	127°
Tri-isopropyl " [3]	"	?
Tri-isobutyl " [4]	"	215°
Tri-isoamyl " [5]	"	about 300°
Tri-phenyl " [6]	Solid	above 360°
Tri-benzyl " [6a]	"	"
Ethyl-isopropyl-isobutyl " [7]	Liquid	about 190°
Methyl-diphenyl " [8]	"	284°
Ethyl-diphenyl " [9]	"	293°
Di-ethyl-phenyl " [10]	"	220°
Di-methyl-ethyl " [11]	"	83°–85°
Di-ethyl-methyl " [12]	"	110°–112°
Di-ethyl-propyl " [13]	"	146°–149°
Di-ethyl-isoamyl " [14]	"	185°–187°
Di-ethyl-benzyl " [15]	"	252°–255°
Ethyl-dibenzyl " [16]	"	320°–330°
Dimethyl *p*-tolyl " [17]	"	210°
Di-ethyl *p*-tolyl " [18]	"	240°
Dimethyl xylyl " [19]	"	230°
Diethyl xylyl " [20]	"	260°

The tertiary phosphines hitherto obtained are, with the exception of triphenyl and tribenzyl phosphine, liquids at ordinary temperatures, having a powerful odour. They are insoluble in water, but soluble in ether &c. As a rule, they oxidise rapidly in contact with the air, fuming and growing hot, and in some cases igniting spontaneously. The product of this oxidation is a tertiary phosphine oxide of the formula R_3PO, and, no doubt, of the constitution $R_3P:O$.

The final products of the oxidation of phosphuretted hydrogen, and of primary, secondary, and tertiary phosphines, are therefore respectively: H_3PO_4, RH_2PO_3, R_2HPO_2, R_3PO, the amount of oxygen absorbed by the phosphine decreasing in a regular manner as the series is ascended.

The oxides of tertiary phosphines are solid substances of remarkable stability. They can in the majority of cases be distilled, and even boiled with nitric acid, without change. By no means as yet discovered can they be reduced. Hydracids combine with them, and they give crystalline compounds with a number of metallic salts, such as the chlorides of platinum, zinc, mercury, iron, cobalt, &c., also in some cases with chloride of acetyl, bromine, and sulphur.

Tertiary phosphines also combine with the elements of the sulphur group, forming compounds analogous to the oxides.

The salts of tertiary phosphines are readily obtained by dissolving the bases in acids. They are stable, and are not, as a rule, decomposed by water. Their compounds with hydracids have been chiefly studied; those containing oxy-acids have not been investigated (with very few exceptions). The haloid salts dissociate to a greater or less extent on heating. Their hydrochlorides combine with chloride of platinum to give chloroplatinates of normal composition.

Some of the tertiary phosphines combine with chloracetic acid to give hydrochlorides of phosphorised betaines. At present only two or three of these substances have been obtained – tri-methyl phosphorus betaine by Meyer (*B.* 4, 734), the corresponding ethyl derivative by Hofmann (*Pr.* 11, 530), and in addition to these two the closely allied compound, tri-methyl phosphorus benzo-betaine hydrochloride, by Michaelis a. Czimatis (*B.* 15, 2018), $(CH_3)_3PCl.C_6H_4.COOH$.

The compounds of these phosphorised betaines are stable and well-defined substances. Letts (*Tr. E.* 30, pt. 1, 285) has investigated the reactions and decompositions of the ethylated body, which are of some interest.

The hydrate and the salts of this betaine lose carbonic anhydride when heated, and give rise to the hydrate or salt of methyl-tri-ethyl-phosphonium

$$(C_2H_5)_3PX.CH_2.COOH = CO_2 + (C_2H_5)_3PX.CH_3,$$

a reaction which is entirely analogous to that occurring when the corresponding sulphur compounds (*thetines*) are heated: $(CH_3)_2SX.CH_2.COOH = CO_2 + (CH_3)_2SX.CH_3$. While it is perfectly different from that which the true (nitrogen) betaines experience, as they either dissociate into the original trialkyl-amine and the group $X.CH_2.COOH$ (or the products of its decomposition), or distil unchanged (Brühl, *A.* 177, 214).

Treated with caustic potash, all the salts of tri-ethyl phosphorus betaine yield tri-ethyl phosphine oxide: $(C_2H_5)_3PX.CH_2.COOH + 2KHO = (C_2H_5)_3PO + KX + CH_3.COOK + H_2O$.

Several of the tertiary phosphines combine directly and energetically with a molecule of bisulphide of carbon to give highly characteristic compounds, usually of a red colour, and possibly having the constitution, $R_3P{<}\begin{array}{l}S\\C{:}S\end{array}$. So characteristic and so readily formed is this compound in the case of tri-ethyl phosphine, that its production may be employed as a test either for bisulphide of carbon or for the phosphine itself. As yet these (bisulphide) compounds have been obtained only with methyl, ethyl, and iso-propyl phosphine, and with those of the aromatic phosphines containing ethyl or methyl groups.

According to Czimatis (*B.* 15, 2016) these mixed phosphines combine very easily with bisulphide of carbon if they contain methyl, the readiness with which combination occurs diminishing, however, in proportion to the molecular weight of the aromatic radicle, while, if they contain ethyl, combination occurs only slowly and with difficulty. Hofmann (*Tr.* 1860, 431) has somewhat exhaustively studied the compound of tri-ethyl phosphine and the bisulphide, which forms with explosive violence. Among its properties are the following: It is insoluble in water, difficultly soluble in ether, but easily dissolves in hot alcohol, from which it separates on cooling in red needles like chromic anhydride. From an ethereal solution it is deposited by spontaneous evaporation in large deep-red monoclinic crystals exhibiting dichroism, which melt at 95° and volatilise at 100°. It is soluble in strong hydrochloric acid, and if the solution is mixed with platinic chloride, a yellow amorphous compound is produced, $2(C_2H_5)_3PCS_2,PtCl_4$. When heated with silver oxide or nitrate, it is decomposed as follows: $(C_2H_5)_3PCS_2 + 2Ag_2O = Ag_2S + Ag_2 + CO_2 + (C_2H_5)_3PS$, and moist air produces a similar change. But if is heated with water to 100°C., the following reaction occurs:—

$$4(C_2H_5)_3PCS_2 + 2H_2O$$
$$= 2(C_2H_5)_3PS + (C_2H_5)_3PO + (C_2H_5)_2(CH_3)POH + 3CS_2.$$

Heated with sulphuretted hydrogen, it suffers the following change: $3(C_2H_5)_3PCS_2 + H_2S$
$= 2(C_2H_5)_3PS + (CH_2S)(C_2H_5)_3PCS_2 + CS_2$.

The action of halogens upon tertiary phosphines has not been very fully studied. Probably direct addition would occur in all cases. This has been proved to take place with tri-ethyl phosphine if the halogen is allowed to act very gradually upon it. The chloride $(C_2H_5)_3PCl_2$ thus obtained is crystalline, melting at 100° and volatilising readily, though its boiling-point is high. Similar compounds of bromine and iodine have been obtained.

Compounds of tri-methyl and tri-ethyl phosphine with mustard oils are formed easily, and give crystalline hydrochlorides. They, no doubt, have the constitution, $S{:}C{:}NR{:}PR_3$.

[*Note.*—Some of the aromatic tertiary phosphines, especially tri-phenyl phosphine, have properties which differ materially from those of other tertiary phosphines. Thus tri-phenyl phosphine is a crystalline solid having scarcely any odour, and it does not oxidise spontaneously. It is remarkably stable, and is not attacked by chlorine even when heated. The hydriodide and hydrochloride are formed when it is dissolved in the warm concentrated hydracids, and are crystalline, but on adding water they dissociate. By treating the phosphine with bromine and an alkali, or by oxidising it with hydrochloric acid and chlorate of potash, the hydrate $(C_6H_5)_3P(OH)_2$ is obtained as a crystalline solid. This when heated to 100° readily loses water, and is converted into the oxide, a substance which is not acted upon by bromine, oxygen, sulphur, &c. By dissolving the phosphine in fuming nitric acid a nitrate of the formula $(C_6H_5)_3P(NO_3)_2$ is obtained.]

Tertiary phosphines, apparently without exception, unite with alkyl iodides to form phosphonium salts.

General Properties of Quaternary Compounds (*Phosphonium Salts*). So many of these bodies have been obtained that a list appears inadvisable. It would include derivatives of the series C_nH_{2n+1} to the 5th term, one or two of the series C_nH_{2n-7}, and a large number of mixed phosphoniums containing various radicles, among which are vinyl, allyl, and ethylene.

The phosphonium salts are the most stable of all organic phosphorus compounds. None are decomposed by water, and most of them can be obtained readily in the crystalline state by evaporating their solutions.

As a rule, they are soluble in water and in alcohol. They are readily prepared from their iodides, either by double decomposition with a silver salt, or by first obtaining their hydrates (by the action of moist oxide of silver), and subsequently neutralising the solution with the acid.

The hydrates R_4POH are solid substances, having a powerful alkaline reaction and many properties similar to those of an alkali. Indeed, in the case of tetrethyl phosphonium hydrate, the only remarkable point of difference between it and caustic potash (so far as its reactions with metallic salts &c. are concerned) is that, when added to a zinc or aluminium salt, the zinc or aluminium hydrate, which is at first precipitated, is insoluble in an excess. Phosphonium hydrates are decomposed when heated, and in some cases, when their solutions are boiled or at the moment of production, into a tertiary phosphine oxide and a hydro-carbon,

$$R_4POH = R_3PO + R - H.$$

The action of heat upon the salts of the phosphoniums has been investigated in a number of cases, partly by Letts and N. Collie (*Tr. E.* 30, part 1, 213; *P. M.* August 1886), and partly by the latter chemist alone.

As regards the haloid salts, the chlorides decompose almost quantitatively into a hydrocarbon and a tertiary phosphine hydrochloride (Collie), furnishing an excellent method for 'retrograding' from quaternary to tertiary bodies.

'When the phosphonium chloride contains several ethyl groups, then if more than one of the latter is present, ethylene is always formed, *e.g.*

$$(C_2H_5)_3(C_7H_7)PCl = (C_2H_5)_2(C_7H_7)P.HCl + C_2H_4.$$

But when only one ethyl group is present, then, although ethylene is still formed, two decompositions occur, *e.g.* (1)

$$2(C_2H_5)(CH_3)_3PCl = 2(C_2H_5)(CH_3)_2P.HCl + C_2H_4$$

(2) $(C_2H_5)(CH_3)_3PCl = (CH_3)_3P.HCl + C_2H_4$.

If we compare the decomposition by heat of phosphonium chlorides with the decomposition of any of the compound ammonium salts, it must be with the hydroxides and not with the corresponding chlorides' (Collie, *C. J.* 1888, 636, 714), *e.g.*

$$\begin{aligned}(C_2H_5)_4PCl &= (C_2H_5)_3P.HCl + C_2H_4\\(C_2H_5)_4NOH &= (C_2H_5)_3N + C_2H_4 + H_2O\\(C_2H_5)_3(C_7H_7)P(OH) &= (C_2H_5)_3PO + C_7H_8\\(C_2H_5)_3(CH_3)NCl &= (C_2H_5)_3N + CH_3Cl.\end{aligned}$$

The effect of heat on phosphonium salts derived from oxyacids is completely different. In the case of the ethyl series at all events, they suffer, as a rule, at least two, and occasionally three, different and distinct decompositions. In one of these the molecule splits up into three new groups, consisting respectively of carbonic anhydride, a (paraffin) hydrocarbon, and the tertiary phosphine. In the other, two hydrocarbons are formed—namely, an olefine and a paraffin—in addition to carbonic anhydride and the tertiary phosphine. Whilst in the third, a totally different change occurs, in which only two products are formed—namely, the oxide of the tertiary phosphine and a ketone,

(1)

$$Et_3P<\begin{smallmatrix}C_2H_5\\OOC\,R\end{smallmatrix} = Et_3P + CO_2 + C_2H_5R.$$

(2)

$$Et_3P<\begin{smallmatrix}C_2H_4\,H\\OOC\,R\end{smallmatrix} = Et_3P + CO_2 + C_2H_4 + RH$$

(3)

$$Et_3P<\begin{smallmatrix}C_2H_5\\O\,OCR\end{smallmatrix} = Et_3PO + C_2H_5.CO.R.$$

It is possible, if not indeed probable, that the third reaction occurs subsequently to the first, and that it really depends upon the reducing action of the triethylphosphine upon the carbonic anhydride, at the high temperature at which the decomposition usually occurs, whereby carbonic oxide is liberated, which combines with the hydrocarbon radicle *in statu nascendi*, forming a ketone:

$$Et_3P + CO_2 + (Et) + (R) = Et_3PO + EtCOR$$

$$(\text{or } Et_3P + (OCO - R) + (Et) = Et_3PO + EtCOR).$$

If we merely consider the third kind of decomposition alone, it appears to be, to a certain extent, analogous to the decomposition which a sulphine compound suffers when heated, the difference depending on the greater attraction which phosphorus has for oxygen, compared with that of sulphur for the same element. In both cases a hydrocarbon group is detached from the molecule, and also the residue of the acid, but while with the sulphur compounds these two simply combine (forming a compound ether), and leave a hydrocarbon sulphide, in the case of the phosphonium salt the acid residue is reduced by the tertiary phosphine, and the group thus left combines with the hydrocarbon radicle, forming a ketone.

Thus—

$$Et_2S<\begin{smallmatrix}Et\\OOCR\end{smallmatrix} = Et_2S + EtOOCR.$$

$$Et_3P<\begin{smallmatrix}Et\\O\,OCR\end{smallmatrix} = Et_3PO + EtOCR.$$

A result of this kind is in perfect harmony with the views expressed by Crum Brown and Letts (*Tr. E.* 28, 371; Letts, *Tr. E.* 30, 285) regarding the analogies and differences existing between phosphorus and sulphur and their compounds.

When the phosphonium salts contain ethylene they suffer a different decomposition under the influence of heat; at least this has been ascertained to be the case with the bromide of bromo-ethylene-triethylphosphonium, and the bromide of hydroxy-ethylene-triethyl phosphonium, which decompose as follows (Hofmann):—

$$C_2H_4Br.P(C_2H_5)_3Br = HBr + (C_2H_3)(C_2H_5)_3PBr$$

$$C_2H_4(OH).P(C_2H_5)_3Br = H_2O + (C_2H_3)(C_2H_5)_3PBr$$

and also in that of the hydrate of ethylene-hexethyl diphosphonium, which decomposes according to the equation: $C_2H_4(P(C_2H_5)_3OH)_2 = C_2H_4 + (C_2H_5)_3P + (C_2H_5)_3PO + H_2O$.

Masson and Kirkland (*C. J.* 1889, 126) have studied the action of bromine and chlorine on the salts of tetrethyl phosphonium, the results showing a very close similarity between the polyhaloid derivatives of tetrethyl phosphonium and those of trimethyl sulphine and of tetramethyl ammonium previously described by Dobbin and Masson (*C. J.* 1885, 56; 1886, 846). The tendency to form solid poly-haloid compounds is, however, more marked. For the table, containing a list of the new substances, the methods of forming them, and their chief properties, the original memoir should be consulted.

Organic Phosphorus Compounds which cannot be placed in any of the above Groups.—A phosphorised cacodyl $(CH_3)_4P_2$ (the methyl analogue of liquid phosphoretted hydrogen) was obtained by Thénard (*C. R.* 21, 144, 25, 829) by the action of chloride of methyl on phosphide of calcium, and is interesting not alone as being the sole representative (as yet prepared) of its class, but also as having been probably the first phosphine obtained. Thénard describes it as a colourless, highly refractive liquid, of an odour recalling that of cacodyl itself, insoluble in water, and boiling at about 250°. It inflames spontaneously in contact with air, but if oxidised slowly gives a crystalline acid $(CH_3)_4P_2H_2O_4 = (CH_3)_2PHO_2$ (dimethyl phosphinic acid?), analogous to cacodylic acid. Treated with an excess of hydrochloric acid, it is converted into trimethyl phosphine, and a solid yellow substance $(CH_3)_2P_4$ (which is also formed in the original reaction), and which Thénard regarded as the methyl analogue of solid phosphide of hydrogen.

Michaelis (*B.* 10, 807) obtained a substance, which he named *diphosphenyl* or *phosphobenzene* $C_6H_5.P{:}P.C_6H_5$ (corresponding to azobenzene), by the action of phenyl phosphorous chloride on monophenyl phosphine $C_6H_5PCl_2 + C_6H_5PH_2 = (C_6H_5)_2P_2 + 2HCl$. It is a pale-yellow powder, insoluble in water, alcohol, and ether, but readily soluble in hot benzene, and is slowly oxidised by the air to $(C_6H_5)_2P_2O$. Treated with chlorine, phenyl phosphorous chloride is regenerated. With nitric acid it is oxidised to phenyl phosphinous (benzene phosphinic) acid $C_6H_5PH_2O_2$ if the acid is dilute, but to phenyl phosphinic (benzene phosphonic) acid $C_6H_5PH_2O_3$ if the acid is strong. Treated with hydrochloric acid, it reacts so as to regenerate the substances from which it is formed.

Michaelis (*B.* 7, 499) also obtained a substance, which he called *di-phospho-benzene hydrate* $C_6H_5.P{:}P.OH$, by the action of spontaneously inflammable phosphoretted hydrogen on phenyl phosphorous chloride. It is a yellow powder, soluble with ease in bisulphide of carbon, taking fire on exposure to air, and oxidised by nitric acid to phenyl phosphinic (benzene phosphonic) and phosphoric acids. In addition to the above, Michaelis (*B.* 11, 885) obtained a phenylated solid phosphide of hydrogen $(C_6H_5)HP_4$ by treating phenyl phosphorous chloride with a quantity of water insufficient for complete decomposition (for instance, by keeping it in a badly-stoppered bottle). It is a dark-yellow amorphous body, having a faint odour of phenyl phosphine, soluble in hot bisulphide of carbon, but insoluble in water, alcohol, and ether. Treated with chlorine it reacts as follows: $(C_6H_5)HP_4 + 6Cl_2 = 8PCl_3 + (C_6H_5)PCl_2 + HCl$. Nitric acid oxidises it to a mixture of phenyl phosphinic (benzene phosphonic) and phosphoric acids.

The action of phosphonium iodide on aldehydes has been studied by Girard (*A. Ch.* [7] 2, 50), while that of phosphoretted hydrogen and hydrochloric acid on the same bodies and on ketonic acids has been investigated by Messinger and Engels (*B.* 21, 328, 2919). Girard obtained products of addition containing four molecules of the aldehyde (valeric, propionic, salicylic, and benzoic) to one of phosphonium iodide.

Messinger and Engels obtained similar bodies by acting on the aldehydes with hydrochloric acid and phosphoretted hydrogen. The compounds thus formed are for the greater part solid, crystalline, and fairly stable. By treatment with water they are decomposed, and the aqueous solution gives the reactions of hydrochloric acid and phosphoretted hydrogen. Their constitution is probably represented by the formula $(R.CHOH)_4PCl$. Chloride of tetra-hydroxy-ethylidene phosphine $(C_2H_5O)_4PCl$ is decomposed by caustic potash into the free phosphine $(C_2H_5O)_3PC_2H_4O$ and the hydrate $(C_2H_5O)_4P(OH)$. Benzaldehyde and its mono-nitro- derivative give compounds which differ from those obtained in the fatty series in that they contain no hydracid.

Messinger and Engels have summarised the results of their researches as follows: (1) Phosphoretted hydrogen does not act on an aldehyde alone, but is absorbed if at the same time a hydracid is present. The absorption occurs more completely if the aldehyde is largely diluted with ether. (2) The aldehydes of the fatty series combine with a molecule of phosphoretted hydrogen and a molecule of hydracid, while those of the aromatic series combine with phosphoretted hydrogen only, though in order that the compound shall be formed the presence of the hydracid is necessary. (With benzoic aldehyde the compound has the formula $(C_6H_5COH)_1PH_3$.) (3) The phosphorised derivatives of the fatty series have an unpleasant smell, and are decomposed by water, while those of the aromatic series have no odour, and are nearly insoluble in water. All are soluble with difficulty in ether, and in some cases are insoluble.

By the substitution of a ketonic acid for an aldehyde in the above reaction, compounds are produced in certain cases. Thus lævulic acid gives an oil, and pyruvic acid a solid compound,

either $(CH_3.CO.CO)_3P$ or 
$$\left(CH_3-\overset{\overset{O}{\frown}}{C}-C{=}O\right)_3P,$$

which is a well-defined crystalline body, having neither basic nor acid properties, soluble in alkalis with decomposition, and also decomposed when heated with acids. It dissolves, however, without change in glacial acetic acid, and crystallises out on cooling. Boiled with water, it is decomposed into the substances from which it was originally produced. It forms crystalline compounds with aniline, phenyl hydrazine, and toluene diamine. E. A. L.

PHOSPHINIC ACIDS. The name oxy-ethyl-phosphinic acid has been given to the acid $CHMe(OH).PO(OH)_2$, which is got from aldehyde by successive treatment with PCl_3 and water. A more appropriate name for this acid is, however, oxy-ethane-phosphonic acid, the term phosphinic acid being reserved for acids $R'P(OH)_2$ containing trivalent phosphorus.

PHOSPHINO-BENZENE $C_6H_5PO_2$. *Phosphenylic anhydride.* [100°]. Formed from phosphenylic acid and $POCl_3$ (Michaelis a. Rothe, *B.* 25, 1747). White crystalline powder, v. sol. water, being reconverted into phosphenylic acid.

PHOSPHINO-ψ-CUMENE $C_6H_2Me_3PO_2$. [216°]. Formed from $C_6H_2Me_3.PO(OH)_2$ and $C_6H_2Me_3POCl_2$ (Michaelis a. Rothe, *B.* 25, 1749). Plates (from benzene), v. e. sol. chloroform. Converted by hot water into ψ-cumene phosphonic acid.

PHOSPHINO-TOLUENE $C_6H_4Me.PO_2$. *Toluene phosphonic anhydride.* [101°]. Formed from $C_7H_7.PO(OH)_2$ and $C_7H_7.POCl_2$ (Michaelis a. Rothe, *B.* 25, 1748). Converted by water into toluene phosphonic acid.

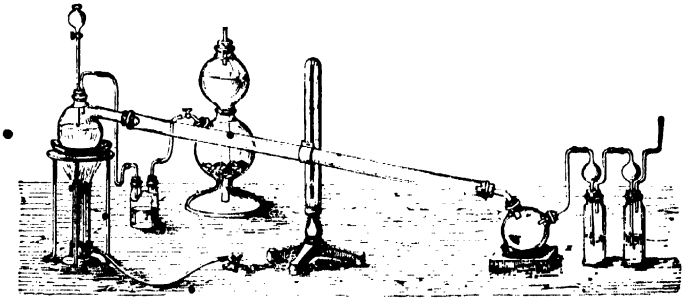
PHOSPHITES. Salts of the acid H_3PO_3; *v.* PHOSPHORUS, OXYACIDS OF, p. 151.

PHOSPHO-. *Use of this prefix applied to inorganic compounds;* for *phospho- acids, phospho- salts,* &c., *v.* the acids, salts, &c., to which *phospho-* is prefixed. Thus, phosphomolybdic acid and phosphomolybdates are described under MOLYBDENUM, ACIDS OF, AND THEIR SALTS.

PHOSPHO-AMIDO-BENZENE SULPHONIC ACID $PO_3H_2.NH.C_6H_4.SO_3H$. The *chloride* $C_6H_5NSPO_3Cl_2$ [158°] is formed from *p*-amido-benzene sulphonic acid and PCl_5 (Laar, *J. pr.* [2] 20, 250). It is converted by MeOH and alcohol into Me_3A''' [114°] and Et_3A''' [102°] respectively.

PHOSPHOBENZENE $C_6H_5P{:}PC_6H_5$. [150°]. Formed by slowly adding $C_6H_5PH_2$ to $C_6H_5PCl_2$ in a current of H (Köhler a. Michaelis, *B.* 10, 812). Yellowish powder, insol. water, alcohol, and ether, sol. benzene. On exposure to air it is oxidised to $(C_6H_5P)_2O$. Dilute HNO_3 oxidises it to phosphenylic acid. Chlorine, diluted with CO_2, forms $C_6H_5PCl_4$. Conc. HClAq forms phenyl-phosphine and $C_6H_5PO_2H_2$.

PHOSPHONIUM COMPOUNDS. PH_3 combines with the halogen acids HX to form compounds PH_3HX. The reactions of these compounds are most simply expressed by regarding them as salts of the radicle PH_4; following the analogy of the ammonium compounds, the bodies PH_4X are called *phosphonium* compounds. The mol. weights of these compounds have not been determined.



PHOSPHONIUM BROMIDE PH_4Br. H.F. $[PH^3,HBr] = 23{,}000$; $[P,H^4,Br] = 44{,}100$ (solid PH_4Br from H, solid P, and liquid Br) (Ogier, *C. R.* 89, 705). Colourless cubes; melts at 30°. V.D. 27·7 corresponding with that required by $PH_3 + HBr$ (Bineau, *A. Ch.* [2] 68, 431). Deliquesces in air; decomposed violently by water to PH_3 and HBrAq. Prepared by bringing together PH_3 and HBr (Serullas, *S.* 64, 238); by leading PH_3 into cold conc. HBrAq (Ogier, *C. R.* 89, 705); by heating conc. HBrAq with P to 100°-120° (Damoiseau, *C. R.* 91, 883).

PHOSPHONIUM CHLORIDE PH_4Cl. Formed in colourless crystals, melting at c. 25°, by subjecting a mixture of equal volumes HCl and PH_3 to 20 atmos. pressure at 14°, or by cooling to −25° under ordinary pressure (Ogier, *C. R.* 89, 705). Skinner (*Pr.* 1887. 283) found the critical temp. to be 48° under 95 atmos.; and the maximum vapour-pressure line to be below those of HCl and PH_3 at all temperatures; from −30° to 10° the line was normal, above 10° combination began; at temperatures near the critical the volume of liquid PH_4Cl formed was nearly half that of the liquid constituents.

PHOSPHONIUM HYDROXIDE. (?)PH_4OH. When PH_3 is strongly compressed in presence of water the PH_3 liquefies and floats on the water. If the pressure is now suddenly decreased, white crystals are formed; these crystals are probably PH_4OH (no analyses have been made). The production and dissociation of the crystals occur at definite pressures and temperatures. No formation occurs above 28° at any pressure. The crystals can be distilled from one part of the tube to another by gently warming (Cailletet a. Bordet, *C. R.* 95, 58). When equal volumes PH_3 and CO_2 are compressed in presence of water, below 22°, the gases disappear and white crystals are formed, which C. a. B. (*l.c.*) take to be a mixture of PH_4OH and the hydrate $CO_2.8H_2O$ discovered by Wroblewski (*C. R.* 94, 954).

PHOSPHONIUM IODIDE PH_4I. H.F. $[P,H^4,I] = 29{,}500$ (solid PH_4I from H, solid P, and solid I); $[PH^3,HI] = 24{,}100$ (solid PH_4I from gaseous PH_3 and HI) (Ogier, *C. R.* 89, 705). This compound was discovered by Labillardière and Gay-Lussac (*A. Ch.* [2] 6, 304), and more fully examined by Serullas (*S.* 64, 238) and H. Rose (*P.* 24, 151; 46, 636).

Formation.—1. By bringing together PH_3 and HI as gases or in conc. aqueous solutions.—2. By the action of gaseous PH_3 on I (Hofmann, *A.* 103, 355).—3. By the action of red P on conc. HIAq at 160° (Oppenheim, *Bl.* [2] 1, 163).—4. Along with P_2I_4, by the action of HI gas on P at ordinary temperatures (Damoiseau, *C. R.* 91, 883).—5. By the action of a little water on PI_3 (*v. Preparation*).—6. By the reaction of HI on H_3PO_2 and warming the product in CO_2 (Lissenko, *B.* 9, 1313).

Preparation.—P and I are combined in CS_2 solution, and the product is decomposed by a little water (Baeyer, *A.* 155, 269; Hofmann, *B.* 6, 286). Hofmann (*l.c.*) gives the following directions: 400 g. P are dissolved in the same weight of dry CS_2 in a retort of 1 litre capacity, and to this solution, *kept cool,* 680 g.

I are added by small portions. The *whole* of the CS_2 is then distilled off on a water-bath, an operation which takes 9 or 10 hours. The retort is then connected with a long wide condensing tube, and a two-necked globular receiver, from which a connecting tube passes to two condensing bottles, the first containing dilute HIAq, the second water (see fig.). Heat is then applied to the retort, gently at first, and 240 g. water are *slowly* added through the drop-funnel. PH_4I and HI are formed; the HI collects in the condensing bottles, and the PH_4I forms a crust, chiefly in the tube, and in smaller quantity in the globular receiver, which, to prevent stoppage, should be connected with the long tube by a wide tube. To prevent the liquid in the condensing-bottles from being forced back in consequence of the rapid absorption, a slow stream of CO_2 is passed through the apparatus during the whole operation. A well-conducted sublimation may be completed in 8 or 9 hours. When it is finished one end of the long condensing tube is closed with a cork, and the PH_4I is detached by means of a stout wire bent and sharpened at the end. Hofmann expresses the reaction thus: $13P + 9I + 21H_2O = 7PH_4I + 3H_4P_2O_7 + 2HI$. The PH_4I may be sublimed in dry HI.

Properties.—Large, clear, lustrous, pyramidal crystals; boils at c. 80°; may be sublimed in HI.

Reactions.—1. With *carbon compounds* reacts as a very energetic reducing agent, and is much used in preparing phosphines &c. (*v.* PHOSPHINES).—2. Decomposed rapidly by *water* or *alkali solution*, evolving non-inflammable PH_3 (*v.* PHOSPHORUS TRIHYDRIDE, *Preparation* 2, p. 136). 3. With *alcohol* forms EtI and PH_3; if the reaction is conducted in a sealed tube PEt_3 and PEt_4I are produced.—4. With *phosphorus trichloride* forms P_2I_4, HCl, PH_3, and solid P_2H (de Wilde, *B.* 16, 217).—5. PH_4I is inflamed by contact with many conc. *acids*, *e.g.* HNO_3, HCl, HBr, HI.

PHOSPHONIUM SULPHATE. When PH_3 is passed into H_2SO_4 at ordinary temperatures much heat is produced, S separates, and SO_2 is formed. The reaction is much slower if the acid is cooled by ice and salt; if the H_2SO_4 is cooled to −20° or −25° (by rapid evaporation of CH_3Cl) a syrupy liquid is formed, from which a white, crystalline, very deliquescent solid separates; this solid seems to be phosphonium sulphate [?$(PH_4)_2SO_4$] (Besson, *C. R.* 109, 644). Exposed to air, H_3PO_4, H_3PO_3, and H_3PO_2 are formed with SO_2, S, and a little H_2S; dissolves in water with hissing noise and evolution of PH_3, but no reduction of the H_2SO_4. M. M. P. M.

PHOSPHORIC ACIDS. In this article are described the three acids, H_3PO_4, HPO_3, and $H_4P_2O_7$; the salts of these acids are described under PHOSPHATES (p. 106); for the other oxyacids of P and their salts *v.* PHOSPHORUS, OXYACIDS OF, AND THEIR SALTS (p. 149). The oxide P_2O_5 is the anhydride of three acids: cold water added to P_2O_5 forms HPO_3, the long-continued action of moist air on HPO_3 produces $H_4P_2O_7$, and H_3PO_4 is formed by boiling for some time an aqueous solution of HPO_3 or $H_4P_2O_7$. The three acids may be formulated as $P_2O_5.H_2O$, $P_2O_5.2H_2O$, and $P_2O_5.3H_2O$ (*cf.* PHOSPHATES, p. 106).

ORTHOPHOSPHORIC ACID H_3PO_4. (*Phosphoric acid. Tribasic phosphoric acid.*) S.G. 1·88 (Schiff, *A.* 113, 183). Melts at 41·75°; liquid solidifies at 38°, temperature rising to 40·5° (Berthelot, *Bl.* [2] 29, 3). H.F. $[P,O^4,H^3]$ = 302,600 (formation of solid acid); 300,080 (formation of molten acid); $[P,O^4,H^3,Aq]$ = 305,290 (*Th.* 2, 225). Heat of fusion = −2520 (*Th.*, *l.c.*). One mol. w. of the molten acid in grams occupies 52·02 c.c. (*Th.*, *l.c.*). μ_A 1·3584, μ_D 1·363, μ_H 1·3746, for H_3PO_4Aq, S.G. 1·11 (=29 p.c.) (Gladstone, *C. J.* [2] 8, 101, 147). Affinity in aqueous solution = c. 25 (HNO_3 = 100) (Ostwald).

Formation.—1. By oxidising P, by long exposure to moist air (Leeds, *A.* 200, 286; Wenzell, *Ph.* [3] 14, 24), or by HNO_3, $HClO_3$, $HClO_4$, SO_3, NO_2, &c.; phosphates are formed by treating P with many metallic oxides, and with alkali carbonates.—2. By oxidising H_3PO_3Aq or H_3PO_2Aq by ClAq, BrAq, or IAq, HClOAq, HNO_3, or by Ag_2O or HgO; H_3PO_3Aq is oxidised to H_3PO_4Aq by standing in air.—3. By reaction of boiling water with P_2O_5, HPO_3, or $H_4P_2O_7$.—4. By burning PH_3 in moist air or O.—5. By reaction of water with $POCl_3$, or much water with PCl_5.—6. By oxidising, by HNO_3Aq, the mixture of H_3PO_3Aq and H_3PO_4Aq obtained in making HI by the action of P, I, and H_2O (Pettenkofer, *A.* 138, 57).—7. By decomposing many phosphates, *e.g.* $Ca_3P_2O_8$, by H_2SO_4; $Pb_3P_2O_8$ decomposed by H_2S in presence of water gives H_3PO_4Aq. For production from bones *v.* DICTIONARY OF APPLIED CHEMISTRY.—8. By decomposing $(NH_4)H_2PO_4$ by warm conc. HClAq, separating NH_4Cl after cooling, and evaporating with HNO_3 till all NH_4 salts and HCl are expelled (Joly, *C. R.* 102, 316).

Preparation.—One part P is mixed with 10–12 parts HNO_3Aq (free from H_2SO_4) S.G. 1·2 (the acid must not be more conc. than this) (Kranthausen, *Ar. Ph.* [3] 10, 410) in a large retort, the beak of which passes loosely into a receiver placed in cold water; about ·3 to ·6 g. I is added for 100 g. P; the retort is gently warmed until the P has completely dissolved. Should any liquid distil over, it is returned to the retort. Oxidation proceeds more regularly, and at a lower temperature, when a little I is present than when HNO_3Aq alone is used (Horn, *Ph.* [3] 10, 468; Ziegler, *D. P. J.* 258, 239). If I is not added, and the acid is more conc. than S.G. 1·2, violent explosions may occur. Von Schrötter recommends the employment of amorphous P and acid more conc. than S.G. 1·2. When the P is all dissolved, the contents of the retort are boiled, and 5–7 parts of the liquid are distilled off (the distillate is HNO_3Aq, S.G. 1·1 to 1·14). During this part of the process copious evolution of NO_2 often occurs, due to the oxidising action of HNO_3 on H_3PO_3. According to Reinsch (*J. pr.* 28, 385) little NO, but much N, is formed during the oxidation of P by HNO_3 at boiling temperature in absence of air, but much NO is produced in an open vessel at low temperatures. The liquid in the retort is evaporated in a basin until the fumes cease to turn blue litmus red. During this operation NO_2 is often freely given off (especially if little or none of this gas has been produced in the retort), as the oxidation of H_3PO_3 is not always completed until the liquid has been evaporated; should no gas be evolved it is advisable to add a little conc. HNO_3Aq to the liquid in the basin after concentration, and again evaporate till acid fumes cease to come off. The liquid in the basin is diluted with water, saturated with H_2S, kept in a warm place for 24 hours, and filtered from As_2S_3 (and Sb_2S_3); which may separate (ordinary P generally contains As). The filtrate is then evaporated, at a temperature not above 150°, until it becomes a thick syrup on cooling, and the cold liquid is placed over H_2SO_4, when it slowly solidifies. By evaporating the syrup *in vacuo* over H_2SO_4, crystalline tablets of H_3PO_4 are obtained; a fragment of these placed in acid S.G. 1·8 (or more conc.) immediately causes crystallisation (Huskisson, *B.* 17, 161).

Properties.—A thick semi-solid mass, S.G. 1·88 (Schiff, *A.* 113, 183); also obtained in crystalline tablets by evaporation of the syrup S.G. 1·88 *in vacuo* over H_2SO_4. According to Berthelot (*Bl.* [2] 29, 3) crystals of H_3PO_4 melt at 41·75°; the liquid solidifies at 38°, with a rise of temperature to 40·5°. H_3PO_4 is tribasic, forming salts $M^IH_2PO_4$, $M^I_2HPO_4$, and $M^I_3PO_4$ (*v.* PHOSPHATES, p. 107). The affinity of H_3PO_4 in aqueous solution is about 25 ($HNO_3 = 100$) (Ostwald). Both crystalline and syrup-like H_3PO_4 deliquesce in air. The acid dissolves readily in water; Hager (in his commentary to the *Pharmacopœia Germanica*) gives the adjoining table.

According to Sieber (*Ph.* [3] 9, 598), H_3PO_4Aq containing ·5 p.c. acid (or even less) stops putrefaction.

Reactions.—1. *Heated* to c. 213°, $H_4P_2O_7$ is formed; at a higher temperature HPO_3 begins to be formed, and at full red heat only HPO_3 is produced.—2. Is not decomposed by electric current, according to Luckow (*Fr.* 1880. 1); by electrolysis of H_3PO_4Aq, using C poles, Bartoli a. Papasogli (*G.* 11, 239, 468; 12, 113, 117, 125) obtained a substance containing C and P, which they called *phosphomellogen.* Molten H_3PO_4, on electrolysis, gives off H and O, and forms $H_4P_2O_7$, then HPO_3, and then H_3PO_3, and inflammable P hydride (Janecek, *C. C.* 1888. 273).—3. It is not certain whether *water* forms hydrates with H_3PO_4, when the acid is dissolved in water (*v.* Crompton, *C. J.* 53, 116).—4. By adding *alkali* solutions to H_3PO_4Aq till neutral, salts M_2HPO_4 are formed; addition of considerable excess of alkali produces M_3PO_4. For connection between quantity of alkali added and electrical conductivity of the solution, *v.* D. Berthelot (*C. R.* 113, 851).—5. Reacts with *phosphorus pentachloride* at ordinary temperatures to form $POCl_3$ and HCl; with *phosphorus oxychloride* when hot to form HPO_3 and HCl, or $H_4P_2O_7$ and HCl, according to the relative quantities of H_3PO_4 and $POCl_3$; with *phosphorus trichloride* to form HPO_3, H_3PO_3, and HCl; and with *metaphosphoric acid* to form $H_4P_2O_7$ (Geuther, *J. pr.* [2] 8, 359). For reactions of salts of H_3PO_4 *v.* PHOSPHATES, p. 107. For *nitriles* of H_3PO_4 *v.* PHOSPHAM (p. 104), and PHOSPHORUS OXYNITRIDE (p. 144); for *amide* and *imido amide* *v.* PHOSPHAMIDES (p. 105) and PHOSPHAMIDO-IMIDE (p. 105). For *thio-amide* *v.* PHOSPHORUS SULPHOCHLORIDE, *Reaction* 7 (p. 148).

PYROPHOSPHORIC ACID, $H_4P_2O_7$.

Preparation.—1. An impure acid, containing some H_3PO_4 and HPO_3, is obtained by heating H_3PO_4 to 213° until a little dissolved in cold

water gives a white pp., without a trace of yellow Ag_3PO_4, with $AgNO_3Aq$, after neutralisation by NH_3Aq.—2. Péligot (*A. Ch.* [2] 73, 286) obtained crystals of $H_4P_2O_7$ by allowing glacial HPO_3 to stand in moist air in a bottle for some years. Crystals of H_3PO_4 formed at the top of the bottle, a liquid S.G. 1·7 in the middle, and crystals of $H_4P_2O_7$ at the bottom.—3. An aqueous solution of $H_4P_2O_7$ is obtained by decomposing $Pb_2P_2O_7$ suspended in water by H_2S, filtering from PbS, and allowing the H_2S to evaporate at the ordinary temperature (Geuther, *J. pr.* [2] 8, 359).—4. By heating together H_3PO_4 and HPO_3 in the ratio HPO_3:H_3PO_4.—5. By the reaction of H_3PO_4 and $POCl_3$ in the ratio $5H_3PO_4$:$POCl_3$ (G., *l.c.*).

Properties and Reactions. — A glass-like solid; Péligot (*A. Ch.* [2] 73, 286) obtained the acid in non-transparent crystals resembling loaf-sugar. Dissolves readily in water; dilute solutions remain unchanged at ordinary temperatures (Graham), when heated H_3PO_4Aq is formed. The solution, neutralised by NH_3Aq, gives a white pp. of $Ag_4P_2O_7$ with $AgNO_3Aq$. $H_4P_2O_7$ is tetrabasic; for description of salts *v.* PHOSPHATES, p. 107. When heated with PCl_5 reacts according to relative masses used: (1) $H_4P_2O_7 + 5PCl_5 = 7POCl_3 + 4HCl$; (2) $H_4P_2O_7 + PCl_5 = 2HPO_3 + POCl_3 + 2HCl$ (Geuther, *J. pr.* [2] 8, 359). PCl_3 heated with $H_4P_2O_7$ forms HPO_3, H_3PO_3, and HCl; $POCl_3$ produces HPO_3 and HCl (G., *l.c.*). For the *amic acids* of $H_4P_2O_7$, and other amic acids derived from hypothetical condensed pyrophosphoric acids, *v.* PHOSPHAMIC ACIDS (p. 105).

METAPHOSPHORIC ACID HPO_3 (Graham, *T.* 1833. 253).

Preparation.—1. H_3PO_4Aq or $H_4P_2O_7Aq$ is evaporated to dryness and the residue heated to full redness until H_2O ceases to be evolved.—2. PbP_2O_6 is suspended in water and decomposed by H_2S, the filtrate from PbS is evaporated to dryness and heated to full red heat.—3. By heating together H_3PO_4 and $POCl_3$ in the ratio $2H_3PO_4$:$POCl_3$, or $H_4P_2O_7$ and $POCl_3$ in the ratio $2H_4P_2O_7$:$POCl_3$, or $H_4P_2O_7$ and PCl_3 in the ratio $3H_4P_2O_7$:PCl_3 (Geuther, *J. pr.* [2] 8, 359).—4. By reacting on H_3PO_3Aq with Cl or Br.—5. A solution of P_2O_5 in a little cold water contains HPO_3.

Properties and Reactions.—According to Tammann (*J. pr.* [2] 45, 417), two varieties of HPO_3 exist; one is a soft, silky mass, formed by heating H_3PO_4 until one molecule of H_2O is removed; the other is obtained by heating H_3PO_4 until it sets to a glassy mass on cooling. A transparent, colourless, glass-like solid. Ordinary *glacial phosphoric acid* is impure HPO_3, generally containing considerable quantities of Na salts, and some H_3PO_4 or $H_4P_2O_7$. Very hygroscopic, soon deliquesces in air. Volatilised completely at bright-red heat (H. Rose, *A.* 76, 2, 13; 77, 319). Not dehydrated by heat nor by the action of dehydrating agents. Heated with PCl_5 forms $POCl_3$ and HCl, HPO_3Aq is changed to H_3PO_4Aq, slowly at ordinary temperatures, more rapidly by boiling or by adding HClAq or HNO_3Aq. (For rate of change *v.* Sabatier, *C. R.* 106, 63; 108, 738, 804.) HPO_3 is monobasic; several series of metaphosphates, some polymeric and some isomeric, exist (*v.* PHOSPHATES, p. 106).

Historical.—In the early part of the seventeenth century a substance was prepared by heating heavy spar with combustible organic matter, *e.g.* egg-white and charcoal, and this substance glowed in the dark (Kopp, *Geschichte der Chemie*, iv. 42). From this time the name phosphorus was given to any substance which emitted light in the dark without being ignited (φωσφόρος = light-bearer). The substance now known as phosphorus was prepared for the first time about 1670; Brand seems to have been the discoverer, but the discovery is sometimes attributed to Kunkel or to Boyle (for details *v.* Kopp's *Geschichte der Chemie*, iii. 327).

For a long time P was prepared in very small quantities; it was obtained by evaporating urine, mixing the residue with sand, and heating in a very hot fire. In 1737 charcoal was mixed with the sand and urine-residue. The discovery of

**phosphates in bones by Scheele in 1771, and in minerals by Gahn in 1780, led to the preparation of P on a comparatively large scale. The discovery of P played an important part in the development of the phlogistic theory. Phosphorus was supposed to be a compound of phlogiston with the acid which was formed when P was burnt; this acid was composed of phlogiston and muriatic acid according to Stahl, and of vitriol and muriatic acid according to Hofmann. Marggraf in 1743 determined that P increased in weight when burnt, and that P was obtained by heating phosphoric acid with combustible matter. In 1777 and 1780 Lavoisier showed that P was a constituent of phosphoric acid (*cf.* Kopp, *l.c.*).

Occurrence.—P is not found uncombined. Phosphates of Al and Ca occur in large quantities in many rocks; phosphates of Fe, Pb, Mg, and NH_4 &c. are also widely distributed minerals. Coprolites (the fossilised excrements of former land-animals) and guano (the excrement of certain birds) consist very largely of Ca phosphate. Phosphates also occur in some kinds of coal (Carnot, *C. R.* 99, 154). Phosphates of Ca and Mg are found in the ashes of plants and the bones of animals; P occurs in combination with C, H, and N in the yolk of eggs, in blood, in semen, and in nerve and brain matter.

Formation.—Ordinary phosphorus is formed: 1.—By heating $CaPO_3$ with powdered charcoal, $3Ca(PO_3)_2 + 10C$
$= 4P + 10CO + Ca_3(PO_4)_2$; or with SiO_2 and charcoal, $2Ca(PO_3)_2 + 10C + 2SiO_2$
$= 4P + 10CO + 2CaSiO_3$.—2. By reducing $Pb_3(PO_4)_2$ with charcoal (Donovan, *P. M.* [4] 2, 202; Fourcroy a. Vauquelin, *Gmelin's Handb.* [6th edit.] i. 2, 95).—3. By decomposing a strongly-heated mixture of $Ca_3(PO_4)_2$ and C by HCl (Cari-Montrand, *C. R.* 38, 864).

Red phosphorus is formed: 1. By the action of light, heat, or electricity on ordinary P, whether the P be solid or in solution, dry or moist, at ordinary temperature or at −14° (Schrötter, *W. A. B.* 1, 130; 8, 241; 9, 414; Corenwinder, *A. Ch.* [3] 30, 242; Lallemand, *C. R.* 70, 182; Hittorf, *P.* 126, 193; V. Meyer, *B.* 15, 297; Grove, *C. J.* 16, 269).—2. By heating common P with a little I. One part of I suffices to transform c. 100 parts of P into the red variety, by melting the P, mixing in the I, and heating again; the mass becomes red at 100°, at 120°-130° a red powder separates, at 200° a more or less explosive action occurs and the change is complete (Brodie, *J. pr.* 58, 171).—3. By adding a little I to a solution of common P in CS_2, evaporating to dryness, adding water, and washing with CS_2 (Corenwinder, *A. Ch.* [3] 30, 242; Lallemand, *C. R.* 70, 182; Brodie, *J. pr.* 58, 171). Rüdorff (*P.* 128, 463) supposed the red substance thus formed to be a hydride of P.

1. **Crystalline ordinary phosphorus** is formed: 1. By heating red P in a vacuous sealed tube to 447° (Hittorf, *P.* 126, 193).—2. By dissolving ordinary P in molten lead and crystallising therefrom (H., *l.c.*).

Preparation.—1. The details of the preparation of **ordinary phosphorus** from bone-ash are described in DICTIONARY OF APPLIED CHEMISTRY, vol. iii. Ordinary P frequently contains notable quantities of As, derived from the H_2SO_4 used; this can be removed only by repeated treatment with dilute HNO_3Aq, S.G. 1·1, a process which involves the loss of about $\frac{5}{8}$ of the P (Herz a. Bärwald, *B. B.* 32, 2, 133; *cf.* Dulk, *ibid.* 34, 1, 247; also Wackenroder, *J. pr.* 2, 340; and Liebig, *A.* 11, 260). Traces of red P may be removed by shaking in a closed vessel with conc. $K_2Cr_2O_7$Aq and H_2SO_4 (Wöhler, *A.* 45, 249). Lockyer (*C. N.* 40, 101) found that a specimen of dry P gave off considerable quantities of H when heated *in vacuo*.

2. **Red or amorphous phosphorus.**—A small flask of hard glass is fitted with a good cork carrying a short tube and an exit-tube which dips just beneath the surface of a little Hg; the entrance tube is fitted with a stopcock. Dry CO_2 is passed through the apparatus for some time; a dry stick of common P is then placed in the flask, and the stream of CO_2 is continued for a little, after which the stopcock is closed, and the flask is heated on a sand-tray or in an oil-bath, to 240°-280°, for 50-60 hours. After cooling, a layer of red P is found at the bottom of the flask, generally covered by a mixture of the two kinds of P. The ordinary P is melted by running in a little water at 50°-60°; the water and melted P are poured off; the residual red P is washed repeatedly with CS_2 (addition of $CaCl_2$Aq, 38°-39° *Beaumé*, causes the CS_2 solution to rise to the surface; Nicklès, *C. R.* 42, 646), or with boiling KOHAq S.G. 1·3, and then with water containing a little HNO_3; the red P is finally washed with water, and dried at c. 100° (Schrötter, *W. A. B.* 1, 130; 8, 241; 9, 414).

The change of common into red P occurs in ten minutes by heating the former to 300° in sealed tubes of thick glass, from which the air has been pumped out (Hittorf, *P.* 126, 193; V. Meyer, *B.* 15, 297).

3. **Crystalline metallic phosphorus.** Hittorf (*P.* 126, 193) claimed to have formed a distinct variety of P by heating red P in sealed tubes of hard glass to c. 447° (in vapour of S); and also by dissolving common P in molten lead and crystallising. A wide tube of hard glass is closed at one end, filled to $\frac{1}{4}$ with common P, and then filled with pieces of lead; the open end is narrowed, and the air is pumped out of the tube, which is then sealed. The tube is embedded in calcined MgO, placed in an iron tube, and heated above the melting-point of Pb for 8-10 hours. After cooling, the Pb is dissolved in HNO_3Aq, S.G. 1·1, and violet-black crystals of P remain; these crystals have not, however, been obtained quite free from lead.

Properties.—P exists in three, and perhaps in more than three, modifications.

1. ***Ordinary, octahedral, or stick phosphorus*** is a semi-transparent, colourless, crystalline solid, with a very distinct smell. The smell is very probably due to a mixture of ozone and P_2O_3, formed by the oxidation of the P (Schönbein, *P.* 65, 377; Thorpe a. Tutton, *C. J.* 57, 573). When melted and cooled quickly P is opaque; when cooled slowly it is nearly as clear as water. P must be kept under water; if the water is free from air the P remains transparent (Baudrimont, *C. R.* 61, 857). In ordinary water**

P becomes covered with a whitish film, but this again becomes transparent at c. 50° (H. Rose, *P.* 27, 563; Baudrimont, *l.c.*). According to Marchand (*J. pr.* 20, 506) the white film contains from ·4 to ·7 p.c. water; Pelouze (*A. Ch.* [2] 50, 83) regarded this substance as a hydrate of P, and Mulder (*J. Ph.* 23, 20) as a compound of oxide with hydride of P. When melted in large quantity and allowed to cool slowly, fairly large dodecahedral and octahedral crystals separate (Hautwein a. Buchner, *Kastn. Arch.* 10, 127, 504; Whewell, *C. N.* 39, 144; Hermann, *B.* 6, 1415). At ordinary temperatures P is as soft as wax; when cooled it becomes brittle. Exposed to light, P soon becomes yellow and then red on the surface. In a vacuum tube, or in a tube filled with an indifferent gas, P easily sublimes in colourless, transparent, very lustrous crystals (Hermann, *B.* 6, 1415; Mitscherlich, *B. B.* 1855. 409; Blondlot, *C. R.* 63, 397; Desains, *C. R.* 23, 149). Melted P often remains liquid many degrees below its m.p.; this is shown especially when P is melted by warming with alcoholic KOH solution, or when a solution of P in CS_2 is gradually evaporated under water (H. Rose, *P.* 32, 469; Kallhofert, *J. pr.* 50, 1). In some cases P remains liquid at c. −15°. P may be obtained in finely-divided particles by melting it under water, and shaking carefully in a flask until the P solidifies; if pure P is melted under a solution of sugar, gum, dextrin, NH_4Cl, $(NH_4)_2CO_3$, &c., and shaken until it solidifies, the P is obtained in a state of extremely fine division (Casaseca, *J. Ph.* 16, 202; Blondlot, *J.* 1865. 126; Schiff, *A.* 118, 88; also *A. Suppl.* 4, 37). P is slightly sol. water, alcohol, ether, ethereal and fatty oils, and hot conc. acetic acid (Vulpius, *Ar. Ph.* [3] 13, 38). Water shaken with P loses the smell and taste of P, and ceases to glow in the dark when it has been exposed to air for a time (Müller, *B.* 3, 84). P is very soluble in CS_2, S_2Cl_2, and liquid P_2S.

P volatilises in water-vapour, even at the ordinary temperature; when P is distilled in steam and the distillate is cooled rapidly, the P is obtained as a white snow-like mass (Remsen a. Kaiser, *Am.* 4, 459); it is also often obtained in this form by distilling crude HIAq containing P (Hell, *J.* 1883. 312).

P oxidises very easily; slowly when exposed to low temperatures, and more rapidly as the ignition-temperature, 60°, is approached. When P is burnt in air or O it emits very bright yellow-white light, and much heat is produced. But if H is passed over slightly warmed P, or if a stream of the warm gas is charged with a very little P, the issuing gas glows with a very feeble greyish-white light, scarcely visible in daylight; the temperature of this flame is very low: if the H is ignited an emerald-green cone appears in the interior of the H flame (for spectrum of this green cone *v.* Christofle a. Beilstein, *C. R.* 56, 399; Salet, *A. Ch.* [4] 28, 56). The glowing of P in the dark was formerly supposed to be due to the evaporation of the P (Corne, *J. Ph.* [5] 6, 17; Marchand, *J. pr.* 50, 1). It was shown that P glows in an indifferent gas only when small quantities of O are present; also that P neither oxidises nor glows in pure O at the ordinary pressure, but only when the O is diluted with an indifferent gas or the pressure is diminished; and also that the glowing is stopped by the presence of H_2S, PH_3, SO_2, CS_2, Br, Cl, N_2O, NO_2, &c. (Fischer, *J. pr.* 35, 342; 39, 48; Schrötter, *J. pr.* 58, 158; Müller, *B.* 3, 84; Joubert, *C. R.* 78, 1853; Deschamps, *C. R.* 52, 355; Müller-Erzbach, *B.* 12, 2130; Chappuis; *Bl.* [2] 35, 419; *cf.* Thorpe, 'On the Glow of Phosphorus,' *N.* 41, 523). Much work has been done to determine whether ozone or H_2O_2, or both, is formed when P oxidises in moist air; the question is not yet finally settled (McLeod, *C. J.* 37, 118; Kingzett, *C. J.* 37, 792); Leeds (*N. Y. Acad. of Sciences*, 1, 363, and 3, 150) has given a full index to the memoirs on the subject. Schmid (*J. pr.* 98, 414) determined that ozone is not formed when P oxidises in dry O. P is extremely poisonous; the lethal dose for adults is from ·2 to ·5 g. Burns with P are very dangerous; the parts should be rapidly and thoroughly washed with dilute bleaching powder solution.

The atomic weight of P has been determined, (1) by ppg. Ag and Au solutions by P and determining the ratio of Ag : P and Au : P (Berzelius, *G. A.* 53, 433; *P.* 8, 17); (2) by finding the Ag needed to ppt. Cl from PCl_3 (Pelouze, *C. R.* 20, 1047; Dumas, *A. Ch.* [3] 55, 174); (3) by oxidising red P in O to P_2O_5 (Schrötter, *J. pr.* 53, 435); (4) by analysing and determining V.D. of PCl_3, PF_5, &c.; (5) by measuring S.H. of P.

Determinations of the S.G. of P vapour made by Dumas, Mitscherlich, and Deville a. Troost at temperatures from 500° to 1000° gave numbers agreeing with the molecular wt. $P_4 = 124$. Biltz a. V. Meyer (*B.* 22, 725) obtained the values 52·5 at 1480°, 46·7 at 1680°, and 45·5 at 1700° for V.D. of P, showing that at a white heat the mol. formula is probably P_2 (V.D. = 31).

The mol. wt. of ordinary P in solution in C_6H_6 was determined by Paterno a. Nasini (*B.* 21, 2153) by the cryoscopic method; values were obtained between P_2 and P_4. Hertz, using the same method and the same solvent, obtained the value $124 = P_4$ (*Z. P. C.* 6, 358). Beckmann also found $124 = P_4$ for P in solution in CS_2 by the method of raising of boiling-point of the solvent (*Z. P. C.* 5, 76).

The action of light, heat, or electricity on P changes it into allotropic red P. Light affects the change whether the P be in air or another gas, or *in vacuo*, whether water be present or not (Schrötter, *W. A. B.* 1, 130, 8, 241; 9, 414), at temperatures as low as −14°, and whether the P be solid or dissolved in CS_2 (Corenwinder, *A. Ch.* [3] 30, 242; Lallemand, *C. R.* 70, 182). For an account of the action of tropical sunlight on P in CS_2 *v.* Pedler, *C. J.* 57, 599. The action of heat begins at c. 215° at the ordinary pressure; diminution of pressure causes a slackening of the rate of change, and the action stops at 393 mm. pressure, temp. being 215°. The change is complete by heating to 260° for c. 8 days; at 300°, in a sealed tube, it is finished in a few minutes (Schrötter, *l.c.*; Hittorf, *P.* 126, 193; V. Meyer, *B.* 15, 297; *cf.* DISSOCIATION, vol. ii. p. 391). The change is accomplished by electricity by passing the current through a little P in a closed tube with Pt wires fused into the ends (Grove, *C. J.* 16, 269; Geissler, *P.* 152, 171). Hittorf (*P.* 126, 193) regards the action as due to the heating of the P vapour by the current. Certain reagents also effect the change: *e.g.* heating with a very little I (Brodie, *J. pr.* 58, 171); or heating a solution of P in CS_2 with I (Corenwinder, *A. Ch.* [3]. 30, 242; Lallemand, *C. R.* 70, 182), but Rüdorff (*P.* 128, 463) says the product is a hydride of P. In the change of 62 g. ordinary P into red P c. 7,100 g.-units of heat are produced; and there is a contraction of volume (*v.* Petersen, *Z. P. C.* 8, 601).

2. *Amorphous or red phosphorus* is a dull, dark carmine, odourless, tasteless powder, which becomes darker on heating, and black when boiled with KOHAq. It is brittle, and shows no trace of crystalline form. Amorphous P is heavier, and conducts electricity much better, than crystalline P, although its conductive power is very small compared with the metals (*v.* data at beginning of this article). Amorphous P does not melt when heated to redness in a sealed tube (Hittorf, *l.c.*); vapour is formed in the tube, and on cooling this solidifies as crystalline P, but the unvapourised portion remains amorphous. When distilled, amorphous P becomes crystalline; the action begins at c. 260° (Schrötter, *l.c.*). The process, like the reverse change of crystalline into amorphous P, is essentially one of dissociation (*v.* DISSOCIATION, vol. ii. pp. 391-3). Amorphous P takes fire at c. 250°-260° (Hittorf, Schrötter, *l.c.*), but active combustion begins at c. 300°; it does not oxidise in dry air, but in presence of moisture oxidation proceeds slowly, with the smell of ozone and the formation of an acid liquid (Personne, *C. R.* 45, 113; Wilson, *Ph.* 17, 410; Pedler, *C. J.* 57, 599). Red P does not glow in the air; it is not poisonous (De Vrij, *J.* 1851. 313). This variety of P is insoluble in the menstrua which dissolve ordinary P; boiling turpentine, and a few liquids of high boiling-points, dissolve a little and change it into ordinary P.

3. *Crystalline metallic phosphorus* is described by Hittorf (*P.* 126, 193) as forming long, black, thin, rhombohedral crystals which appear red in transmitted light; S.G. 2·34 at 15·5°; less volatile than amorphous P; heated in a sealed tube drops of ordinary P appear at c. 358°. It is doubtful whether this is a distinct variety of P; it does not seem to have been obtained free from Pb (for preparation, *v. ante*). According to Troost and Hautefeuille (*C. R.* 78, 748), the S.G. and heat of combustion of red P change continuously with temperature; at 580° ruby-red crystals appear, which have the S.G. of Hittorf's metallic P.

Thénard observed that P became black when heated and suddenly cooled (*Gm.-K.* [6th ed.] i. 2, 102); some experimenters claim this to be a special variety of P (*v.* Reichardt, *Ar. Ph.* [3] 9, 442; P. Thénard, *C. R.* 95, 409); according to others it contains foreign substances. Blondlot obtained it only when a trace of Hg was present (*C. R.* 70, 856; 78, 1130); Ritter found the presence of As necessary (*C. R.* 78, 192).

Napoli (*C. R.* 25, 369) thought that a special yellow modification of P was produced by keeping freshly-melted ordinary P under water.

The atom of P is trivalent in most gaseous molecules, *e.g.* PCl_3, PH_3, PF_3, &c.; it is pentavalent in the gaseous molecule PF_5. P acts as a non-metallic element; its oxides are acidic, although some of them combine with less acidic oxides to form salt-like compounds. P is closely related to As, Sb, and Bi, and also to N, V, Nb, Di, Er, and Ta; these elements form Group V. For a detailed consideration of the chemical relations of P *v.* NITROGEN GROUP OF ELEMENTS, vol. iii. p. 571. The specific volume of P at its b.p. is 20-21 (Pisati a. de Franchis, *B.* 8, 70; Ramsay a. Young, *C. J.* 39, 50); the specific volume of P in combination is c. 25·3 (Thorpe, *C. J.* 37, 333).

Reactions and Combinations.—1. P combines with *oxygen* to form P_4O, P_2O_3, and P_2O_5; the reaction begins at ordinary temperature with crystalline P, and at c. 250°-260° with amorphous P. (For more details *v.* PHOSPHORUS, OXIDES OF, p. 138.) P does not combine with pure O at the ordinary pressure, but only when an indifferent gas is present, or the pressure is diminished (for references *v. Properties of P*, p. 128). The combination of P in O is arrested in proportion to the dryness of the O (Baker, *C. J.* 47, 349; *Pr.* 46, 1). Amorphous P does not oxidise in dry *air*, but the oxidation proceeds slowly in moist air. Ordinary P oxidises readily in moist air; it is not yet finally settled whether or not ozone is produced (*v.* McLeod, *C. J.* 37, 118). In moist air H_3PO_3 is formed; this may be a direct product of oxidation, or it may result from the reduction of H_3PO_4 formed by the direct oxidation of the P (*v.* Schönbein a. Bohlig, *J.* 1863. 167; Blondlot, *C. R.* 66, 351; Stiassny, *D. P. J.* 199, 414).—2. P is easily changed to P_2O_5 by *oxidising agents*, *e.g.* HNO_3, CrO_3, KNO_3, &c. A mixture of P and $KClO_3$ explodes violently when struck or rubbed; the explosion is less violent with amorphous P. Amorphous P is inflamed when rubbed with CrO_3, PbO_2, Pb_3O_4, HgO, $K_2Cr_2O_7$, or Ag_2O, and when heated with MnO_2, CuO, or KNO_3.—3. P combines with *sulphur*, the *halogens*, and many *non-metals* when heated with these. The reactions occur at lower temperatures, and more rapidly, with ordinary than with amorphous P, yet amorphous P combines with Br and Cl at the ordinary temperature.—4. P decomposes solutions of *salts of copper*, *silver*, and some *other metals*, with separation of the metal, which often combines with the P.—5. Boiling *water* is slightly decomposed by P *in presence of air*, with formation of PH_3, H_3PO_2Aq, and H_3PO_4Aq (Cross a. Higgin, *C. J.* 35, 254); at 250° the reaction is more rapid (Schrötter); with amorphous P the action is slow (C. a. H.).—6. *Concentrated hydrochloric acid* is decomposed by P at 140°, with formation of PH_3 and H_3PO_3Aq (Oppenheim, *Bl.* [2] 1, 163).—7. *Hydriodic acid* reacts with P to form PH_4I and PI_2; *hydrobromic acid* reacts at 100°-120° to produce PH_4Br (Damoiseau, *C. R.* 91, 883).—8. *Chlorosulphonic acid* [$SO_2.OH.Cl$] reacts explosively with ordinary P at 25°-30°, and more slowly and at a higher temperature with amorphous P, to form SO_2, HCl, and H_3PO_4 (Heumann a. Köcklin, *B.* 15, 416).—9. *Sulphuryl chloride* [SO_2Cl_2] produces PCl_3 and SO_2; the reaction is violent, even with amorphous P (H. a. K., *B.* 15, 1736).—10. Adie (*C. J.* 59, 230) describes the action of *sulphur trioxide* on P as producing $3P_2O_4.2SO_3$.—11. With *boiling solutions of alkalis* P forms PH_3 and alkali salts of H_3PO_2. P left for a long time in contact with *ammonia solution* probably forms P hydride and NH_4 phosphite (*v.* Blondlot, *C. R.* 57, 1250; Commaille, *C. R.* 68, 263; Flückiger, *J.* 1868, 171). Red P is not acted on by NH_3Aq (F., *l. c.*).—12. Heated with the *alkaline earths* P forms phosphides and phosphates.—13. When P is strongly heated with *anhydrous alkali carbonates* C is separated. For an account of the technical applications of P *v.* Dictionary of Applied Chemistry; for description of the methods of testing for P and estimating it a *manual of analysis* must be consulted.

Phosphorus, acids of. The *phosphoric acids* are described under that heading (p. 124), the other acids under the heading Phosphorus, oxy-acids of, and their salts (p. 149). For *phosphamic acids v.* p. 105, and for *thiophosphamic acids v.* Thiophosphoryl chloride, *Reaction* No. 7, p. 148.

Phosphorus, bromides of. P and Br combine violently; two products of the reaction have been isolated, PBr_3 and PBr_5. These formulæ are probably molecular.

Phosphorus tribromide, PBr_3 (*Phosphorous bromide*). B.P. = 172·9° at 760·2 mm. (Thorpe, *C. J.* 37, 335). S.G. $\frac{0°}{4°}$ 2·92311 (T., *l.c.*). Does not solidify at −13·6°. A colourless liquid, with very penetrating odour; fumes in the air. PBr_3 is formed by the direct union of P and Br. If P is added to Br, the Br must be kept in a freezing mixture, and the P must be added in extremely small pieces until a colourless liquid is obtained; the process is dangerous. Lieben (*A.* 146, 314) recommends to pass CO_2 through slightly warmed Br, to lead the gas over small pieces of dry P, and to distil the liquid thus produced after it has stood for some days. Schorlemmer uses amorphous P. The P is placed in a flask connected with an inverted condenser, and having a dropping funnel passing through the cork. Br is added drop by drop from the funnel: the first few drops combine, with a production of flame, but after a little the Br may be added more freely; the PBr_3 is distilled from the excess of P (*v.* also Pierre, *A. Ch.* [3] 20, 5; Kekulé, *A.* 130, 16; Löwig, *Gm.-K.* i. 2, 334).

PBr_3 is not acted on by O; reacts with S to form $PSBr_3$ (Gladstone, *P. M.* [3] 35, 345); Cl forms PCl_5 and Br; $HgCl_2$ forms PCl_3 and $HgBr_2$; H_2S produces P_2S_3 and HBr. PBr_3 is decomposed slowly by cold water, rapidly at 25°, to HBrAq and H_3PO_3Aq (Löwig, *l.c.*). P and I dissolve in PBr_3.

Phosphorus pentabromide, PBr_5 (*Phosphoric bromide. Perbromide of phosphorus*). Produced by adding excess of Br to PBr_3, stirring well with a glass rod, and after a time removing the excess of Br by warming very gently in a stream of dry CO_2. Also formed by action of Br on PCl_3 in presence of a little I (Gladstone, *P. M.* [3] 53, 345). PBr_5 forms a citron-yellow solid; fumes in the air; melts to a red liquid when gently warmed, which solidifies again to rhomboidal crystals, which are yellow if cooling has been rapid, and red if cooling has been slow. The red crystals become yellow when rubbed (Baudrimont, *Bl.* 1861. 118); at a higher temperature (below 100°) gives red vapours that condense to yellow needles. PBr_5 is separated at c. 100° into PBr_3 and Br, which re-combine on cooling. (Ogier, *C. R.* 92, 83) gives the following heats of formation: $[P,Br^5] = 63,000$ from liquid Br; $= 83,000$ from gaseous Br; $= 62,300$ from solid Br; in each case solid PBr_5 is formed.

Reactions.—1. Heated to 200° in *oxygen*, PBr_5 inflames with formation of P_2O_5 (Baumstark, *A.* 140, 75).—2. Neither *hydrogen* nor *sulphur* reacts in the cold with PBr_5.—3. *Chlorine* forms PCl_5 and Br; *iodine* produces PBr_3 and IBr_3.—4. In *moist air*, $POBr_3$ is formed (*q. v.*).—5. A *little water* produces HBr and $POBr_3$; with *much water* HBr and H_3PO_4 are formed.—6. PBr_5 reacts with *hydroxides* to substitute OH by Br; the reaction is similar to, but not so energetic as, that of PCl_5.—7. *Hydrogen sulphide* forms $PSBr_3$ and HBr.—8. *Phosphorus hydride* forms at first PBr_3, and then also P and HBr.—9. *Hydriodic acid* has no action; dry *boric acid* forms some BBr_3 (Gustavson, *B.* 3, 426); dry *oxalic acid* produces $POBr_3$, HBr, CO, and CO_2. 10. *Antimony sulphide* produces $SbBr_3$ and $PSBr_3$ (Baudrimont, *Bl.* 1861. 118).—11. With many *metals* at high temperatures, PBr_5 produces phosphides and bromides.

Combination.—With *ammonia* to form $PBr_5.9NH_3$. Prepared by passing dry NH_3 into a solution of PBr_5 in CCl_4 (Besson, *C. R.* 111, 972).

Phosphorus, bromochlorides of. Several compounds of P, Br, and Cl are formed by the reaction of PCl_3 with Br. PBr_2Cl_3, PBr_4Cl_3, or PBr_8Cl_3 is produced according to the relative quantities of PCl_3 and Br used; and from one or other of these the compounds PBr_7Cl_2 and $PBrCl_4$ are obtained. According to Stern (*C. J.* 49, 815) PBr_2Cl_3 is formed, and on addition of more Br the compound PBr_3Cl_2 is produced, and unites with Br to form PBr_5Cl_2; the whole of the Cl in PCl_3 cannot be thus replaced by Br (Michaelis, *B.* 5, 9, 411; Wichelhaus, *A. Suppl.* 6, 277; Stern, *C. J.* 49, 815; Geuther, *J. Z.* 10, 128; Michaelis a. Geuther, *J. Z.* 6, 242; Prinvault, *C. R.* 74, 868). Michaelis regarded PBr_4Cl_3 and PBr_8Cl_3 as compounds of PBr_2Cl_3 with Br_2 and $3Br_2$ respectively; Prinvault looked on PBr_4Cl_3 as $PBr_3Cl_2.BrCl$, and PBr_8Cl_3 and PBr_7Cl_3 as $PBr_5.3BrCl$ and $PBr_5.2BrCl$, respectively. Against Prinvault's view it was urged by Michaelis that if the compounds contain PBr_5 they must give $POBr_3$ and BrCl by reacting with SO_2, whereas the products are $POCl_3$, SBr_4, and Br; but Geuther showed that $POBr_3$ reacts with BrCl to give $POCl_3$ and Br. Geuther regarded the compounds as containing trivalent Br atoms.

Phosphorus dibromotrichloride, PBr_2Cl_3. Yellow-red crystals, melting at 35°; obtained by gradually adding 160 pts. Br to 137·5 pts. PCl_3, and keeping in a closed tube in a freezing mixture for some time (M.). Addition of 18 pts. water reacts thus (G. a. M.): $3PBr_2Cl_3 + 3H_2O = 2POCl_3 + POBr_3 + 3HCl + 3HBr$. If SO_2 is passed into the contents of the tube, SBr_4 and $POCl_3$ are formed (M.)

Phosphorus tetrabromotrichloride PBr_4Cl_3. Large dark-red crystals with a blue sheen; formed by adding Br slowly to PCl_3 till two layers are produced, the lower of which is dark and oily, and then adding PBr_2Cl_3 until the lower layer solidifies (G.). Also produced by warming PBr_5 with PCl_5 to 40°:

$4PBr_5 + 6PCl_5 = 5PCl_3 + 5PBr_4Cl_3$ (G.), when heated PBr_4Cl_3 melts and separates into two layers, which unite again on cooling. A little H_2O produces $POCl_3$, $POBr_3$, HCl, HBr, and Br: much H_2O forms H_3PO_4, HCl, HBr, and Br; SO_2 produces $POCl_3$, SBr_4, and Br.

PHOSPHORUS OCTOBROMOTRICHLORIDE PBr_8Cl_3. Brown needles, melting at 25°. Formed by adding 4⅔ pts. Br to 1 pt. PCl_3 (*i.e.* in the ratio $8Br : PCl_3$), heating to 65°, and allowing the oily liquid to cool to c. 4°; much heat is produced in the reaction (P.). Geuther (*l.c.*) says the compound is also produced by adding BrCl to PBr_5 in the ratio $PBr_5 : 3BrCl$.

PHOSPHORUS HEPTABROMODICHLORIDE PBr_7Cl_2. Prismatic crystals. Obtained by rapidly distilling the preceding compound at a little above 90° (P.); also by dropping PCl_3 into Br until two layers are formed, and allowing to stand. Soluble in PCl_3.

PHOSPHORUS MONOBROMOTETRACHLORIDE $PBrCl_4$. According to Prinvault (*l.c.*) this compound is obtained, as yellow crystals, by heating to boiling a solution of the preceding compound in PCl_3, also by the reaction of PCl_3 with BrCl. P. says that PBr_8Cl_3 and PCl_3 react in accordance with the equation $PBr_8Cl_3 + PCl_3 = PBr_7Cl_2 + PBrCl_4$.

Phosphorus, bromofluoride of, PBr_2F_3. A liquid, which fumes in the air, and is violently decomposed by water; also decomposed easily by heat to PBr_3 and PF_5; formed by passing PF_3 into Br (Moissan, *C. R.* 100, 1348).

Phosphorus, bromonitride of, PBr_2N. This compound is said to be formed by heating the product of the action of NH_3 on PBr_5, in a sealed tube, to 250°–275°, with twice its weight of PBr_5 for twelve hours, and then heating the resulting substances under reduced pressure, when PBr_5 sublimes, and then at 200° a white crystalline sublimate of PBr_2N is formed; the compound is purified by resubliming *in vacuo*. The crystals melt at 188°–190°; sublime at 150° *in vacuo*; sol. ether, less sol. CS_2 or $CHCl_3$, insol. water (Besson, *C. R.* 114, 1479).

Phosphorus chlorides of. P and Cl combine directly and easily, with the production of light and much heat. Two compounds are thus produced, PCl_3 and PCl_5; these formulæ are molecular. According to Donny a. Mareska (*C. R.* 20, 717), and Dumas (*A. Ch.* [3] 55, 172), liquid Cl surrounded by solid CO_2 combines with P.

PHOSPHORUS TRICHLORIDE PCl_3 (*Phosphorous chloride*). Mol. w. 137·07. Boils at 75·95° at 760 mm. (Thorpe, *C. J.* 37, 333; *v.* also Pierre, *A. Ch.* [3] 20, 5; Haagen, *P.* 131, 122). S.G. $\frac{0°}{4°}$ 1·61275 (Thorpe, *l.c.*); V.D. 70·6 (Dumas, *A. Ch.* [3] 55, 172). S.H. of vapour ·1347, equal weight of air = 1; ·64, equal vol. of air = 1 (Regnault, *J.* 1863. 85). μ for H line $a = ·3222$; $\frac{\mu - 1}{d}$. Mol. w. = 44·3 (Haagen, *P.* 131, 122). H.F. [P,Cl^3] = 75,300 (*Th.* 2, 408; formation of liquid PCl_3). Regnault (*J.* 1863. 65) gave the vapour pressures of PCl_3 in mm. of Hg as follows:—87·98 at 0°, 62·68 at 10°, 100·55 at 20°, 155·65 at 30°, 233·78 at 40°, 341·39 at 50°, 485·63 at 60°, 674·23 at 70°.

Formation.—1. By direct union of P and Cl.—2 By reaction of P with $HgCl_2$, $FeCl_3$, $CuCl_2$, ICl_3, S_2Cl_2, or $SeCl_2$ (*Gm.-K.* **1**. **2**, 390).—3. By reaction of Cl or $HgCl_2$ with PBr_3 or PI_3 (*l.c.*).—4. By decomposing PCl_5 by heat aided by H, P, PH_3, I, HI, S, or one of several metals.—5. By heating HPO_3 with NaCl (*Gm.-K.*, *l.c.*).—6. By heating Na_2HPO_4 with NH_4Cl (H. Rose).—7. By heating P with conc. HClAq (Oppenheim, *Bl.* [2] 1, 163).—8. By passing $POCl_3$ through a tube filled with glowing charcoal (Riban, *C. R.* 95, 1160).

Preparation.—About 500–600 g. P, in pieces about 1 inch long, are dried quickly, twice, between filter-paper, and placed in a dry retort of c. 1 litre capacity, through the neck of which a stream of dry CO_2 is kept passing. The beak of the retort is now passed into a well-cooled receiver, and the tubulus is connected with an apparatus which is evolving dry Cl. The tube through which the Cl passes into the retort is fixed somewhat loosely in the cork, so that it may be moved up or down easily. The retort is placed in warm water until the P is melted; after the action has fairly begun, the heat produced suffices to keep the P molten. A large basin with cold water is kept beneath the retort in case the latter should break. The reaction is regulated by moving the tube from the Cl apparatus near to, or away from, the surface of the P; if this tube is too near the P, the heat of the reaction vaporises much of the P, which then condenses in a reddish layer in the upper part of the retort; if the delivery-tube is too far from the P, solid PCl_5 forms and deposits on the upper part of the retort in yellow crystals. As the reaction proceeds, pieces of red P appear here and there in the retort. Towards the end much red P is formed; this must be heated carefully with a lamp, a process in which the retort is apt to be cracked. The distillate is digested with a little P for a few days, to decompose any PCl_5, and then redistilled from a retort heated on a water-bath (Donny a. Mareska, *C. R.* 20, 717; Dumas, *A. Ch.* [3] 55, 172). Thorpe (*C. J.* 37, 333) recommends to heat red P in dry Cl; he says that the reaction is very regular, and that large quantities of PCl_3 may be prepared thus with great ease and rapidity; the red P should be washed with water, then with alcohol, then with ether, and dried at a gentle heat.

Properties.—A clear, colourless, highly refractive, liquid, which can be vaporised without decomposition in absence of moisture; fumes in air with decomposition; does not redden dry blue litmus paper; vapour has an acrid smell and excites tears. Does not solidify at −115° (Natterer, *P.* 62, 133). Does not conduct electricity. Dissolves P; also I (Gladstone, *P. M.* [3] 35, 345). Mixes with C_6H_6, Et_2O, $CHCl_3$, and CS_2. In a gas-flame or alcohol-flame, PCl_3 burns brightly. Sinks in water and then begins to decompose to H_3PO_3Aq and HClAq; if a little warm water is used, amorphous P separates. Slowly decomposes in the dark to PCl_5 and P (Casselmann, *A.* 83, 247). Combines with Cl to form PCl_5. Not acted on by O at ordinary temperatures; $POCl_3$ is slowly formed at b.p. of PCl_3. $POCl_3$ is formed by action of ozone and various O compounds which readily part with O (*v. Reactions*).

Testing PCl_3 *for* $POCl_3$.—PCl_3 has little action on zinc-dust at ordinary temperatures; POCl$_3$ produces P$_2$O$_5$ and Zn phosphide, which is decomposed by H$_2$O, giving inflammable P hydride. To apply this reaction, a few drops of the liquid are added to a little zinc-dust in a test tube, and then a few drops of water; if POCl$_3$ is present, small bubbles of gas are given off, and take fire in the air (Denigès, *Bl.* [3] 2, 787).

Reactions.—1. *Water* produces H$_3$PO$_3$ and HCl; the reaction proceeds somewhat slowly. If a little warm water is added to PCl$_3$, amorphous P separates as the product of a secondary reaction —3 H$_3$PO$_3$Aq + 2PCl$_3$ = 3HPO$_3$Aq + 6HClAq + 2P (Michaelis, *B.* 8, 504; but *cf.* Geuther, *J. Z.* [2] 3, 2*nd Suppl.* 116).—2. *Oxygen* does not react at ordinary temperatures, but POCl$_3$ is slowly formed at b.p. of PCl$_3$ (Michaelis, *J. Z.* 6, 93; Remsen, *Am. S.* [3] 11, 365).—3. *Ozone* rapidly forms POCl$_3$ (Remsen, *l.c.*).—4. *Potassium chlorate* produces POCl$_3$.—5. *Sulphur trioxide* reacts violently, forming POCl$_3$ and SO$_2$ (Michaelis, *J. Z.* 6, 239; 7, 110; Armstrong, *J. pr.* [2] 1, 255; *cf.* Rose, *P.* 44, 304).—6. *Selenion dioxide* produces POCl$_3$ and Se at 110°; if the SeO$_2$ is in excess, SeCl$_2$ and P$_2$O$_5$ are also formed; SO$_2$ has no action at 140° (M., *l.c.*).—7. Heated in a closed tube at 130° with *arsenious oxide*, forms As, AsCl$_3$, and P$_2$O$_5$ (Michaelis, *l.c.*).—8. *Thionyl chloride* forms PCl$_5$, POCl$_3$, and PSCl$_3$. *Chromyl dichloride* produces POCl$_3$, P$_2$O$_5$, PCl$_5$, and CrCl$_3$. 9. *Nitrogen trioxide* or *pentoxide* reacts with strongly cooled PCl$_3$ to form NOCl, P$_2$O$_5$, POCl$_3$, and P$_2$O$_3$Cl$_4$ (Geuther a. Michaelis, *B.* 4, 766).—10. Many *metallic oxides* withdraw Cl from PCl$_3$ forming metallic chlorides; PbO forms Pb and Pb(PO$_3$)$_2$ besides PbCl$_2$.—11. Many *metallic sulphides* when heated with PCl$_3$ react to form P$_2$S$_3$ and metallic chlorides; *e.g.* K$_2$S, BaS, CaS, Sb$_2$S$_3$, PbS, &c. (*v. Gm.-K.* i. 2, 320).—12. *Sulphur* reacts at c. 130° with production of PSCl$_3$ (Henry, *B.* 2, 638).—13. *Antimony* forms SbCl$_3$ and P (*Gm.-K.*, *l.c.*).—14. Red-hot *iron filings* produce Fe phosphide and FeCl$_2$ (*Gm.-K.*).—15. *Zinc*, at 100°, forms ZnCl$_2$ and P (Most, *B.* 13, 2029).—16. *Platinum* and *silver* are not acted on by PCl$_3$ (*Gm.-K.*).—17. *Sulphuric acid* reacts slowly in the cold, rapidly when hot, to form SO$_2$, HCl, P$_2$O$_5$, and SO$_2$.OH.Cl (Michaelis, *J. Z.* 6, 239).—18. *Phosphorous acid* produces P$_2$O$_5$ (*Nacquet's Chem.* German ed. 1868. p. 218). 19. *Hydriodic acid* reacts at the ordinary temperature, forming PI$_3$ and HCl (Hautefeuille, *Bl.* [2] 7, 198, 200, 203).—20. PSCl$_3$ and PCl$_5$ are formed by heating for some hours at 160° with *sulphur chloride.*—21. *Iodine pentabromide* is said to form ICl$_3$ and PBr$_3$.—22. *Phosphorus hydride* produces HCl and solid P$_2$H (Besson, *C. R.* 111, 972). SbH$_3$ is said to be without action (Mahn, *Z.* [2] 5, 729).—23. Heated with *hydrogen sulphide*, HCl and P$_2$S$_3$ are formed (Baudrimont, *A. Ch.* [4] 2, 5).—24. *Ammonia* seems to form various compounds which have not been fully examined (*v.* Phospham, p. 104).—25. Passed over heated *ammonium chloride*, phospham (*q. v.*) is formed.—26. With many *carbon compounds containing hydroxyl*, PCl$_3$ reacts to substitute Cl for OH.

Combinations.—1. With *chlorine*, to form PCl$_5$ (*q. v.*). — 2. With *bromine* to form several bromochlorides (*q. v.*).—3. With *iodine* to form PI$_2$Cl$_3$ (*v.* **Phosphorus iodochloride**, p. 138).—4. With *titanium chloride* to form PCl$_3$.TiCl$_4$ (Bertrand, *M. S.* [3] 10, 1331); also with a few other metallic chlorides, *e.g.* AuCl.—5. With dry *ammonia* to form PCl$_3$.5NH$_3$ (Rose; Besson, *C. R.* 111, 972).

Phosphorus pentachloride PCl$_5$ (*Phosphoric chloride. Phosphorus perchloride*). Mol. w. 207·81. Melts at 148° under pressure; boils at 160°–165°, with partial decomposition to PCl$_3$ and Cl. V.D. varies with temperature; c. 103 in an atmosphere of PCl$_3$ (*v. Properties*). H.F. [P,Cl^5] = 104,996 (*Th.* 2, 408).

Formation.—1. By combining PCl$_3$ with Cl, or by the action of excess of Cl on P.—2. By reacting with PCl$_3$ on PH$_3$, S$_2$Cl$_2$, or SOCl$_2$.—3. By the action of SbCl$_5$ on PH$_3$ (Mahn, *Z.* [2] 5, 729).

Preparation.—PCl$_5$ may be prepared by the action of Cl on P, but the PCl$_5$ is apt to retain pieces of unchanged P, the presence of which may lead to violent explosions; it is, therefore, better to prepare PCl$_5$ from PCl$_3$. PCl$_3$ is placed in a strong flask with a wide neck; the flask is surrounded by a freezing mixture, and dry Cl is passed in by a *wide* tube which reaches almost to, but does not touch, the surface of the liquid. As the contents of the flask get semi-solid they must be thoroughly broken up by a glass rod. The whole of the PCl$_3$ is not changed to PCl$_5$ until Cl has passed for a considerable time; the change is not complete until, after closing the flask, shaking thoroughly, and allowing to stand for some time, the presence of greenish-yellow gas in the flask is quite apparent. Excess of Cl is finally removed by the long-continued passage of a slow stream of dry CO$_2$ (Müller, *Z.* 1882. 295; Gräbe, *Ar. Sc.* [3] 5, 477).

Properties.—A white, or slightly yellow, crystalline solid with a strong odour; crystallises in rhombic plates; fumes in moist air, with decomposition; sublimes without melting under 100°, but melts at c. 148° under considerable pressure; boils at c. 160°–165°, with partial dissociation to PCl$_3$ and Cl, which re-combine on cooling. PCl$_5$ does not conduct electricity (*Gm.-K.* i. 2, 390). Decomposed by O at c. 300°. Burns in a candle-flame.

Vapour density.—The S.G. of the vapour obtained by heating PCl$_5$ is less than that calculated for PCl$_5$, and it decreases as temperature increases until it is equal to half the calculated value. Wanklyn a. Robinson (*C. R.* 56, 547) showed that the vapour contained free Cl, by diffusing into CO$_2$, and that PCl$_3$ was present in the residue. Deville noticed that the vapour showed the colour of Cl, and that the intensity of colour increased as temperature rose (*A.* 141, 147). The V.D. was determined by Cahours at different temperatures, with the following results (*A.* 141, 42; *v.* also Gibbs, *Am. S.* [3] 18, 277, 371):—

Temp.	S.G. (air = 1)	P.c. Dissociation
182°	5·08	41·7
190	4·99	44·3
200	4·85	48·5
230	4·80	67·4
250	4·00	80·0
274	3·84	87·5
288	3·67	96·2
289	3·69	95·7
300	3·65	97·3

The temperature whereat 50 p.c. is dissociated is c. 202°. Wurtz (*B.* 3, 572) showed that, making certain assumptions, the S.G. of PCl_5 vapour formed in an atmosphere of PCl_3 is c. 7·4-6·8, which agrees with that calculated for PCl_5, viz. 7·2.

Reactions.—1. *Heat* dissociates PCl_5 into PCl_3 and Cl, which recombine on cooling (*v. ante*).—2. PCl_5 is decomposed by *water* to HClAq and $POCl_3$, and finally to H_3PO_4Aq with some HPO_3Aq (*Gm.-K.* i. 2, 390). Thomsen gives $[PCl^5,Aq] = 123,440$ (*Th.* 2, 322).—3. *Boric acid* and *antimonic hydrate* react similarly to water (Gerhardt, *A.* 87, 66, 290; Schiff, *A.* 102, 111; 106, 116). *Boric oxide* when heated with PCl_5 forms $B_2O_3.P_2O_5$ and BCl_3 (Gustavson, *B.* 3, 426).—4. *Hydroxides* generally, including *carbon compounds which contain the group OH*, exchange OH for Cl, with production of $POCl_3$ and chloride of the radicle before in combination with OH.—5. *Compounds containing the group SH* generally react similarly to OH compounds; *e.g.* SH.H gives ClH and $PSCl_3$.—6. *Oxides* generally exchange O for Cl_2; *carbon compounds containing the group CO* generally also react in this way.—7. *Oxygen* reacts with vapour of PCl_5 at c. 300°, producing $POCl_3$, P_2O_5, and Cl (*Gm.-K.* i. 2, 390; Wanklyn a. Robinson, *C. R.* 56, 547).—8. PCl_5 vapour mixed with *hydrogen* and passed through a red-hot tube produces HCl, PCl_3, and P (Baudrimont, *Gm.-K.* i. 2, 394).—9. Heated with *phosphorus* PCl_3 is produced.—10. The compound PS_2Cl_5 is formed by distilling PCl_5 with 8 parts of *sulphur* (Gladstone, *C. J.* 3, 5).—11. *Selenion* produces Se_2Cl_2 and PCl_3.—12. *Iodine* forms PCl_3, and ICl which combines with part of the PCl_5 to produce $PCl_5.ICl$ (*Gm.-K.*, *l.c.*).—13. PCl_5 reacts with many *metals* to form metallic chlorides and PCl_3; sometimes P and metallic phosphides are formed (Baudrimont, *J. pr.* 87, 300; 88, 78; Casselmann, *A.* 98, 213). Among the metals which react with PCl_5 are Al, As, Cd, Au, Fe, Pt, K, Na, Sn, and Zn. The metallic chloride formed often combines with the undecomposed PCl_5; this occurs, *e.g.*, with $AlCl_3$, $FeCl_3$, $HgCl_2$, $PtCl_4$, and $SnCl_4$ (Wöhler, *B.* 13, 875; *cf.* Goldschmidt, *C. C.* 1881. 489).—14. *Phosphorus hydride* produces PCl_3 and HCl; with excess of PH_3, HCl, and P are formed.—15. *Antimony hydride* forms PCl_3, $SbCl_3$, and HCl; *silicon hydride* acts similarly but more slowly (Mahn, *Z.* [2] 5, 729; *ammonia* forms phospham (*q.v.*, p. 104) and nitrogen phosphochloride (vol. iii. p. 570); also phosphamidoimide (*q. v.*, p. 105; *cf.* also Besson, *C. R.* 114, 1264).—16. *Sulphur dioxide* produces $SOCl_2$ and $POCl_3$ (Schiff, *A.* 102, 111; 106, 116; Persoz a. Bloch, *C. R.* 28, 86; Kremers, *A.* 70, 297).—17. *Sulphur trioxide* forms $S_2Cl_2O_5$ and $POCl_3$ (Schiff, *l.c.*; Michaelis, *J. Z.* 6, 235, 240, 292; Williamson, *Pr.* 7, 11).—18. *Selenion dioxide* when distilled with PCl_5 forms $POCl_3$, $SeCl_2$, and P_2O_5, $SeOCl_2$ being formed as an intermediate product (Michaelis, *Z.* [2] 6, 465).—19. *Phosphoric oxide* produces $POCl_3$.—20. *Boric oxide* reacts slowly when heated to c. 140° with PCl_5; $BOCl_3$ is probably formed, and on heating more strongly BCl_3 and $B_2O_3.P_2O_5$ remain (Gustavson, *B.* 3, 426).—21. *Nitrogen dioxide* produces NOCl and $POCl_3$ (*Gm.-K.* i. 2, 390).—22. *Silicon dioxide* forms $POCl_3$, and $SiCl_4$ which combines with the excess of PCl_5 (Weber, *P.* 107, 375).—23. Vapour of PCl_5 reacts with many *metallic oxides*, when these are strongly heated, to form $POCl_3$, and metallic chlorides which frequently combine with undecomposed PCl_5. The following react in this way—Al_2O_3, As_2O_3, and As_2O_5 (Hurtzig a. Geuther, *A.* 111, 159; Michaelis, *J. Z.* 6, 239), [no reaction with Sb_2O_5; Schiff, *A.* 102, 111], CdO, Cr_2O_3, Fe_2O_3, MnO_2, MoO_3 (Schiff, *l.c.*), SnO, TiO_2 (Weber, *P.* 107, 375; Tüttscheff, *A.* 141, 111), WO_3 (Gerhardt a. Chiozza, *C. R.* 36, 1050; Schiff, *l.c.*).—24. *Phosphorus sulphide* forms $PSCl_3$ (Weber, *P.* 107, 375; *Gm.-K.* i. 2, 390).—25. *Carbon disulphide* does not react at 100° (Hofmann, *A.* 115, 264); at 200° $PSCl_3$ is produced (Carius a. Fries, *A.* 112, 193), and CCl_4 (Rathke, *Z.* [2] 6, 57).—26. Many *metallic sulphides* when heated are decomposed by vapour of PCl_5 with formation of $PSCl_3$, S_2Cl_2, and metallic chloride; the following react in this way—sulphide of As, Ba, Bi, Cd, Cu, Pb, Na, Sn, Zn (Weber, *l.c.*; Baudrimont, *l.c.*).—27. *Antimony selenide* and *lead selenide* form $SeCl_4$, which forms a double compound with the excess of PCl_5.—28. *Hydriodic acid* produces PCl_3, HCl, and I (Wurtz, *Gm.-K.*, *l.c.*); *hydrobromic acid* is without action (Gladstone, *C. J.* 3, 5); syrupy *phosphoric acid* solution reacts slowly, the vapours of this acid do not act (Gerhardt, *A.* 87, 66, 290; Schiff, *A.* 102, 111; 106, 116; Persoz a. Bloch, *C. R.* 28, 86).—29. Conc. *nitric acid* reacts energetically, forming $POCl_3$ and HCl.—30. *Sulphuric acid* forms $SO_2.OH.Cl$, HCl, and HPO_3, and $S_2Cl_2O_5$ as the result of a secondary reaction (Michaelis, *J. Z.* 6, 235, 240, 292; Williamson, *Pr.* 7, 11; Baumstark, *A.* 140, 75).—31. Many *metallic salts* react with PCl_5; KNO_3 gives NOCl and $POCl_3$ (Nacquet, *Bl.* 1860); sulphites form $SOCl_2$ (Buchanan, *B.* 3, 485); AgF produces AgCl and probably a fluoride of P (Pfaundler, *W. A. B.* 46, 258); $KClO_4$ gives $POCl_3$; KSCy forms $PSCl_3$, S_2Cl_2, and PCl_3; Na_2HPO_4 gives H_3PO_4 and HCl; haloid salts of the alkalis, and also KCy and K_4FeCy_6, are not acted on by PCl_5.

Combinations.—1. With *iodine chloride* to form $PCl_5.ICl$ (*Gm.-K.* i. 2, 390).—2. With *selenion tetrachloride* to form $SeCl_4.2PCl_5$.—3. With many *metallic chlorides* (*cf. Reactions*, Nos. 13 and 23). These compounds are solids, which sublime with partial decomposition when heated, and are decomposed by water (Baudrimont, *J. pr.* 87, 300; 88, 78; Weber, *ibid.* 77, 65; Casselmann, *A.* 83, 258).—4. With *ammonia* to form $PCl_5.8NH_3$; produced by slowly passing dry NH_3 into a solution of PCl_5 in CCl_4 (Besson, *C. R.* 111, 972; 114, 1264).

Phosphorus, chlorobromides of, *v.* PHOSPHORUS BROMOCHLORIDES, p. 130.

Phosphorus, chlorofluoride of, PCl_3F_2. Mol. w. 175·07. V.D. 78. Poulenc (*C. R.* 113, 75).

Preparation.—Two stoppered flasks of c. 500 c.c. capacity are connected by a bent tube, which passes through the stoppers; one flask is filled with dry Cl, and the other with dry PF_3; that containing PF_3 is connected with a bulb full of Hg, which can be caused to flow into the flask and so force the PF_3 into the flask full of Cl. The PF_3 is slowly driven into the other flask, and the PCl_3F_2 thus formed is kept in contact with Hg for some days (without being shaken with the Hg, else some PF_3 may be decomposed) to remove traces of Cl.

Properties — A colourless gas, with very irritating odour; incombustible; liquefied at -8° at ordinary pressure; absorbed and decomposed by water; heated to c. 250° gives PF_5 and PCl_5, also decomposed in the same way by electric sparks.

Reactions.—1. *Heat* produces PF_5 and PCl_5; the action proceeds at c. 250°.—2. *Electric sparks* also produce PF_5 and PCl_5.—3. Heated with *sulphur* to c. 115°, PSF_3 and S_2Cl_2 are formed.—4. Heated with *phosphorus* to c. 120° PF_3 and PCl_3 are formed.—5. Several *metals* when heated to c. 180° produce metallic chloride and PF_3, *e.g.* Al, Fe, Pb, Mg, Ni, and Sn; Hg exerts a slight action at ordinary temperatures, and acts rapidly at 180°; Na seems to absorb PCl_3F_2 entirely.—6. *Water* reacts rapidly; if a little water-vapour is mixed with PCl_3F_2 the products are POF_3 and HCl; if the gas is passed into water, H_3PO_4Aq, HClAq, and HFAq are formed.—7. Absorbed by *alcohol*, with formation of a compound not yet examined.—8. *Ammonia* is absorbed at ordinary temperature, forming a white solid, which is probably $PF_3(NH_2)_2$.

Phosphorus, chloro-iodide of, *v.* PHOSPHORUS IODOCHLORIDE, p. 138.

Phosphorus, chloronitride of, *v.* NITROGEN PHOSPHOCHLORIDE, vol. iii. p. 570. Besson (*C. R.* 114, 1479) recommends to prepare PCl_2N by forming a layer of PCl_5 on the sides of a large flask, by acting on PCl_3 with Cl, then to heat the PCl_5 with NH_3 till it is superficially saturated, and then to heat under reduced pressure.

Phosphorus, compounds of, with hydrogen and oxygen. Those compounds of P, H, and O, which are acids, are described in the articles PHOSPHORIC ACIDS (p. 124), and PHOSPHORUS, OXYACIDS OF, AND THEIR SALTS (p. 149); but two compounds which have been described by Gautier will find a place here. Gautier (*C. R.* 76, 49) says that the compound P_4HO is formed by heating crystallised H_3PO_3 with 5 or 6 times its weight of PCl_3 to 79°, washing with water, and drying at -10°; at between 80° and 100° the products of the reaction are H_3PO_4, HCl, and amorphous P. This compound is described as an amorphous yellow powder; unchanged in air when dry, but oxidised slowly when moist; insoluble in most menstrua; burns when heated in air to c. 260°; burns explosively when heated with CuO; unchanged at 240°-250° in CO_2, but evolves PH_3 at 265°, and at 350°-360° ordinary P distils off; not acted on by dilute acids; oxidised by ordinary HNO_3Aq; conc. H_2SO_4 evolves SO_2 at c. 200°; decomposed by H_2O at c. 170° to H_3PO_2Aq, H_3PO_3Aq, and PH_3; reacts with dilute alkali solutions; NH_3 combines to form a very unstable brown substance. Gautier (*C. R.* 76, 173) described another compound P_5H_3O; obtained by adding PI_2, little by little, to H_2O at 80°-90°, allowing the yellow solution to deposit a flocculent pp., washing this with warm water, and drying *in vacuo*. If water is added slowly to PI_2 the products are HIAq, H_3PO_3Aq, and H_3PO_2Aq. P_5H_3O is described as a pure yellow solid; amorphous, or perhaps showing traces of crystalline form; tasteless and odourless; insoluble in all menstrua; oxidises in air when moist, when dry oxidises slowly at 100°; oxidised violently by HNO_3Aq; evolves SO_2 from H_2SO_4; gives off PH_3 when heated to 135° in CO_2, and ordinary P at 350°; decomposed by dilute alkali solutions to PH_3, H, H_2KPO_2, and HK_2PO_4; combines with NH_3 to form a brown very unstable substance.

Phosphorus, cyanide of, *v.* CYANOGEN PHOSPHIDE, vol. ii. p. 358.

Phosphorus, fluorides of. Two fluorides of P are known, PF_3 and PF_5; these formulæ are molecular. The compounds are gases at ordinary temperatures.

PHOSPHORUS TRIFLUORIDE PF_3. (*Phosphorous fluoride.*) Mol. w. 87·96. V.D. 43·7 (Moissan, *A. Ch.* [6] 6, 433).

Formation.—1. By the reaction of PbF_2 with Cu phosphide (M., *l.c.*).—2. By adding AsF_3 to PF_3 (M., *l.c.*).—3. By the reaction of PbF_2 with PCl_3 or $POCl_3$ (Güntz, *C. R.* 103, 58).—4. By adding PBr_3 to gently heated ZnF_2 (M., *A. Ch.* [6] 19, 286).

Preparation.—1. AsF_3 is dropped into perfectly dry PCl_3; the gas is shaken with a little water, and dried over H_2SO_4 (M., *C. R.* 100, 272). 2. A mixture of well-dried Cu_3P_2 and PbF_2 free from SiO_2 is heated in a brass tube to dull redness, the gas is passed by a leaden tube through two very small bottles (2 or 3 c.c. capacity) containing H_2SO_4, then through pumice soaked in H_2SO_4, and is then collected over Hg.—3. PBr_3 is gradually added to warm ZnF_2, the gas is washed by passing through water, then dried by passing over pumice soaked in H_2SO_4, and collected over Hg (M., *A. Ch.* [6] 19, 286).

Properties.—A colourless gas, condensed to a colourless liquid at -10° and 40 atmos. pressure. The gas is not liquefied at 24° under a pressure of 180 atmos., but liquefaction occurs when the pressure is suddenly reduced to 50 atmos. (Moissan, *l.c.*). PF_3 does not fume in the air; it is very slowly decomposed by water, with formation of H_3PO_3Aq and HFAq; burns when mixed with O; decomposed by heat; also by electric sparks.

Reactions and Combinations.—1. Decomposed by *heat*; in a glass apparatus P and SiF_4 are formed; in contact with Pt black a gas is formed, probably containing F (Moissan, *C. R.* 102, 763).—2. *Electric sparks* slowly decompose PF_3, forming PF_5 and P (Moissan, *C. R.* 102, 763).—3. Burns when mixed with pure *oxygen* and ignited; a mixture of 1 vol. PF_3 and ½ vol. O explodes violently when sparked, with formation of POF_3 (M., *C. R.* 102, 1245).—4. Very slowly decomposed by *water*, with formation of H_3PO_3Aq and HFAq; more rapidly decomposed by steam at 100°.—5. According to Berthelot (*A. Ch.* [6] 6, 358) *potash solution* produces a fluophosphorous acid probably analogous to fluoboric or fluosilicic acid; Moissan (*C. R.* 99, 655) says that a fluoride and a phosphite are formed.—6. Absorbed rapidly by *bromine* with formation of PBr_2F_3 (*v.* PHOSPHORUS BROMOFLUORIDE, p. 131), also by *chlorine*, with formation of PCl_2F_3 (*v.* PHOSPHORUS CHLOROFLUORIDE, p. 133).—7. Decomposed rapidly by solutions of *chromic acid* or *potassium permanganate*.—8. Decomposed by hot *sodium*, *copper*, *boron*, and *silicon* (M., *C. R.* 99, 655).—9. Combines with *ammonia* to form white, flocculent compound, which is decomposed by water (M., *l.c.*).—10. Combines with *fluorine* to form PF_5 (Moissan, *Bl.* [3] 5, 454).

Determination of composition.—The compound was analysed by Moissan (*C. R.* 100, 272) by heating a known volume in a glass vessel, measuring the volume of SiF_4 formed, dissolving the P deposited in HNO_3Aq, and estimating as $Mg{-}NH_4$ phosphate.

Phosphorus pentafluoride PF_5 (*Phosphoric fluoride*). Mol. w. 125·96. V.D. 63·2 to 65·1 (Thorpe, *A.* 182, 201; Moissan, *C. R.* 102, 763; 103, 1257).

Formation.—1. By passing PF_3 into Br at −15°, PBr_2F_3 is formed, and when heated this gives PF_5 and PBr_5 (Moissan, *C. R.* 101, 1490). 2. By the reaction of AsF_3 with PCl_5.—3. By direct combination of PF_3 with F (M., *Bl.* [3] 5, 454).

Preparation.—AsF_3 is added gradually to PCl_5 surrounded by a freezing mixture; the gas which comes off is passed through PCl_5 contained in a tube which is kept cold, and is collected over Hg (Thorpe, *A.* 182, 201).

Properties and Reactions.—A colourless, strongly-smelling gas, which fumes in air and rapidly attacks the membranes of the mouth and the bronchial tubes. Condensed at 15° and 46 atmos. to colourless liquid which does not act on glass (Moissan, *C. R.* 101, 1490); on partially releasing pressure the liquid solidifies, but soon again becomes liquid (M., *l.c.*). Decomposed by powerful *electric sparks* (150–200 mm. long) to PF_3 and F (M., *C. R.* 103, 1257), but not by ordinary sparking (Thorpe, *l.c.*). Incombustible and does not support combustion. Not acted on by heating with *phosphorus* to dull redness, nor with *sulphur* vapour at 440°, nor *iodine* at 500° (M., *l.c.*). In presence of trace of *water* acts on glass, forming SiF_4 and POF_3. Passed over gently-heated *spongy platinum* is partially decomposed to PF_3 and F; when the Pt is heated to dull redness a compound of Pt with P and F, probably $PF_3.PtF_2$, is formed (M., *Bl.* [3] 5, 454).

Phosphorus, fluobromide of; *v.* Phosphorus bromofluoride, p. 131.

Phosphorus, fluochloride of; *v.* Phosphorus chlorofluoride, p. 133.

Phosphorus, haloid compounds of. P combines readily with the halogens, with production of much heat, to form compounds PX_3 and PX_5; besides these, the compound PI_2 is also known. Several compounds of the type PX_3, and at least one of the type PX_5 (viz. PF_5), have been gasified, so that the formulæ are molecular. The haloid compounds of P are decomposed by water, the fluorides only very slowly, with formation of oxyacids of P and halogen acids; these compounds also combine with many other haloid compounds, both of metals and non-metals, to form double salts.

Phosphorus, hydrides of. P and H do not combine directly; but hydrides of P are produced by evolving H in contact with phosphites or hypophosphites. Three hydrides of P have been isolated; PH_3, PH_2 (or P_2H_4), and P_2H (or P_4H_2). Janssen (*Repert. Chim. app.* 3, 393) obtained a crystalline, explosive substance by the reaction of milk of lime with P, to which he gave the formula P_2H_6. At the ordinary temperature and pressure the first hydride is gaseous, the second liquid, and the third solid. The formula PH_3 is molecular; Croullebois (*C. R.* 78, 496) said that the V.D. of the liquid compound shows the mol. w. to be P_2H_4, but no details are given; the mol. w. of the solid compound is unknown. The liquid hydride takes fire in contact with air; the gas inflames in air at c. 150°, and the solid at c. 200°; the processes for preparing gaseous PH_3 generally also produce more or less liquid P_2H_4, the resultant gas is therefore spontaneously inflammable. PH_3 resembles NH_3 in its reactions, but it is much less decidedly alkaline; phosphonium compounds, *e.g.* PH_4I, similar to ammonium compounds, are known.

Phosphorus trihydride PH_3 (*Phosphoretted hydrogen. Phosphine*). Mol. w. 33·96. Liquefies −90°; solidifies −133·5°; melts at −132·5°; boils c. −85° (Olszewski, *M.* 7, 371). S.G. (air = 1) 1·185. V.D. 17·2. H.F. $[P,H^3]$ = 36,600 (Ogier, *C. R.* 87, 210). S. ·112 (Dybrowski, *J.* 1866. 735).

Formation.—The gas obtained by the following methods is never pure PH_3; it contains more or less P_2H_4, and generally also H; it is usually spontaneously inflammable. 1. By evolving H in contact with phosphites or hypophosphites in solution; phosphates are not reduced (*Gm.-K.* i. 2, 138; Fresenius, *Fr.* 6, 203; Herapath, *Ph.* 7, 57). P and H do not combine directly (Fourcroy a. Vauquelin, *A. Ch.* 21, 202; Dusart, *C. R.* 43, 1126).—2. By heating solutions of phosphites or hypophosphites (*Gm.-K.*, *l.c.*).—3. By the action of boiling alkali solutions on P (H. Rose, *P.* 6, 199; 8, 191; 14, 183; 24, 109, 295; 32, 467; 46, 633).—4. By heating P with syrupy H_3PO_4Aq, or with HClAq, HBrAq, or HIAq (Oppenheim, *Bl.* [2] 1, 163).—5. By heating P with water to 200° (Oppenheim, *l.c.*).—6. By long-continued heating P with blood to 35°–41° (Dybrowski, *J.* 1866. 735).—7. By the action of the electric current on moist molten P (Groves, *C. J.* 16, 268).—8. By heating P with H_2O to c. 200°.—9. By decomposing Zn phosphide by dilute acids, or boiling alkali solution (Schwarz, *D. P. J.* 191, 396). According to Lüpke (*C. C.* 1890. ii. 642), the gas obtained by acting on phosphide of Mg, Sn, or Zn with dilute acid is not spontaneously inflammable.—10. By treating Cu phosphide with KCN and a little 80 p.c. alcohol (*Gm.-K.* i. 2, 138).—11. By decomposing phosphides of the alkali or alkaline earth metals by water or dilute acids.

Preparation.—1. A small flask carrying an exit tube is nearly filled with a conc. solution of KOH in 80 p.c. alcohol; small pieces of P are dropped in, and the flask is heated; the gas is passed through a $CaCl_2$ tube to absorb alcohol vapour, and collected over water. The gas thus prepared does not contain more than c. 45 p.c. PH_3 (Hofmann, *B.* 4, 200); it is generally free from the spontaneously inflammable hydride. The gas prepared by the action of KOHAq on P contains some P_2H_4 and much H; it is spontaneously inflammable in air. The simplest way of preparing this gas is to place a few small pieces of P in a little flask which carries a cork with two tubes, one fitted with a stopcock and passing just through the cork, and the other bent like an ordinary gas-delivery tube and dipping under water in a basin; the flask is nearly filled with conc. KOHAq; the tube with the stopcock is attached to the gas-supply, the cork is fitted loosely into the flask, and a stream of coal gas is passed through the apparatus for a few minutes, after which the cork is fitted tightly into the flask, the stopcock is closed, and the flask is heated. During this process the end of the delivery-tube is kept under the surface of the water in the basin. After a few minutes gas is evolved, and each bubble takes fire as it comes into contact with the air after passing upwards through the water in the basin. If the whole of the air is not driven out of the apparatus before the flask is heated, serious explosions may occur.—2. The best way of preparing pure PH_3 is to decompose PH_4I by KOHAq. A small flask is fitted with a caoutchouc cork, which carries a tube furnished with a bulb and stopcock and an exit-tube; pieces of PH_4I about the size of peas are placed in the flask along with several small pieces of glass-rod, KOHAq (c. 1 pt. KOH in 2 pts. H_2O) is allowed to drop from the bulb-tube *very slowly* on to the PH_4I in the flask. Pure PH_3 is evolved without heating; if the KOHAq is added too rapidly the gas may contain a little P_2H_4 and be spontaneously inflammable (Hofmann, *B.* 4, 200; Rammelsberg, *B.* 6, 88). About 1 litre PH_3 is obtained from 7–7½ g. PH_4I (for preparation of PH_4I *v.* PHOSPHONIUM COMPOUNDS, p. 123).

Properties.—PH_3 is a colourless gas, with a very disagreeable smell like that of onions mixed with decaying fish; very poisonous; slightly soluble in water (*v.* beginning of this article). The solution glows in the dark, and deposits amorphous P when exposed to light and air; on boiling, PH_3 is given off. PH_3 is slightly soluble in alcohol, ether, ethereal oils, and blood; it is completely absorbed by solution of bleaching powder, also by Cu_2Cl_2 in HClAq (*v. Combinations*, No. 4). PH_3 combines with the halogen acids to form salts similar to those of NH_4 (*v.* PHOSPHONIUM COMPOUNDS, p. 123); the H of PH_3 is replaceable by organic radicles (*v.* PHOSPHINES, p. 116). PH_3 reduces solutions of salts of heavy metals. PH_3 free from P_2H_4 takes fire in air at c. 150°. The gas prepared as mentioned under *Formation* takes fire immediately on contact with air; it loses this spontaneous inflammability by exposure to sunlight, by passage through a U-tube cooled to −10°, by mixing with small quantities of Al_2O_3, wood charcoal, various gases, &c. (*v.* Graham, *P. M.* 5, 401). These processes remove P_2H_4, to the presence of which the ready inflammability of the gas is due. Addition to PH_3 of $\frac{1}{500}$ of its weight of P_2H_4 causes the gas to become inflammable in air; the presence of $\frac{1}{1000}$ to $\frac{1}{10000}$ of NO_2 produces the same effect (Graham, *l.c.*; *cf.* Landolt, *A.* 116, 193). The gas prepared by the action of KOHAq on PH_4I (*v. Preparation*, No. 2) is described by Hofmann as taking fire when gently warmed, and being sometimes inflamed by the friction of the stopper of the bottle in which the gas may be kept. According to Rammelsberg (*B.* 6, 88), the gas prepared in this way is sometimes spontaneously inflammable. The gas prepared in this way takes fire when passed into conc. $AgNO_3Aq$ (Poleck a. Thümmel, *B.* 16, 2442).

Reactions.—1. PH_3 is decomposed by *heat*; when passed through a red-hot tube, lustrous, amorphous P is deposited (Merz a. Weith, *B.* 13, 718).—2. Decomposed by *electric sparks* to P and H; the process takes place with regularity, 20 c.c. are decomposed in 5–6 mins. with production of P and 30 c.c. H (for description of an apparatus for lecture purposes *v.* Hofmann, *B.* 4, 204).—3. PH_3 burns in *air* at c. 150° with production of P_2O_5 and H_2O; if a cold substance is brought into the flame, yellow-red specks of amorphous P are deposited.—4. No reaction occurs when pure PH_3, free from P_2H_4, is mixed with *oxygen*, but the mixture explodes if the pressure is suddenly lowered; explosion is said to occur after some hours at the ordinary pressure (Labillardière; *v. Gm.-K.* i. 2, 144).—5. Bubbles of PH_3 burn explosively to PCl_3 and HCl if passed into a vessel filled with *chlorine*; if the Cl is diluted with CO_2, the action is slower, and some P separates.—6. *Bromine* and *iodine* react similarly to Cl; if PH_3 is *heated gently with iodine*, some PH_4I is formed.—7. Heated with *sulphur*, H_2S and P sulphide are formed (Jones, *C. J.* [2] 14, 648).—8. *Salts of the alkali metals and of the alkaline earth metals* decompose PH_3, producing phosphites and hypophosphites (Winkler, *P.* 111, 443).—9. Solutions of *salts of heavy metals* generally decompose PH_3, with production of metallic phosphides, which sometimes combine with the excess of the metallic salts (*v.* Kulisch, *A.* 231, 327). $AgNO_3Aq$ forms a yellow compound (? $Ag_3P.3AgNO_3$), and then black Ag_3P which is quickly reduced to Ag (Poleck a. Thümmel, *B.* 16, 2442); $HgCl_2Aq$, according to Ashan (*Chem. Zeitung*, 10, 82, 102), forms a yellow compound $3Hg_3P_2.7HgCl_2$, a red compound $4Hg_3P_2.5HgCl_2$, and a brown compound $Hg_3P_2.HgCl_2$; $PtCl_4$ is said to form $Pt.PH_2$ (Gavazzi, *B.* 16, 2279); chlorides of Cr, Co, Cu, Au, Fe, and Ni are reduced, with formation of phosphides of the metals, or of metal and P.—10. *Potassium permanganate* solution is reduced by PH_3 to Mn_2O_3, K_2HPO_4 being also formed (Gavazzi, *B.* 16, 2279).—11. PH_3 is decomposed by many *oxides, acids*, and *salts, e.g.* by H_2S, SO_2, NO, N_2O, PCl_3, HNO_3 (no reaction at −25°; Besson, *C. R.* 109, 644), H_2SO_4 (*v.* Besson, *l.c.*), $SbCl_3$, &c., also by certain *metals, e.g.* Sb, Cu, Fe, K, and Zn (*v. Gm.-K.* i. 2, 138).—12. With *haloid compounds of arsenic* PH_3 reacts to form haloid acid and phosphide of As (Besson, *C. R.* 110, 1258).—13. With an ethereal solution of *bismuth bromide* forms a black lustrous body, probably $PBrH(BiBr_2)_2$ (Cavazzi a. Tivoli, *G.* 21, ii. 306).

Combinations.—1. With the *halogen acids* to form compounds of the type PH_4X (X = Cl, Br, or I); combination with HI and HBr occurs at the ordinary temperature and pressure, with HCl combination occurs at −30° to −35° under the ordinary pressure, or at 14° under a pressure of 20 atmos. (Ogier, *Bl.* [2] 32, 483; *v.* also Skinner, *Pr.* 42, 283). At very low temperatures PH_3 seems to combine with H_2SO_4 (*v.* PHOSPHONIUM SULPHATE, p. 124). The compounds PH_4X are described under PHOSPHONIUM COMPOUNDS, p. 123.—2. When PH_3 is strongly compressed in presence of *water*, the gas liquefies and floats on the water. If the pressure is now suddenly released, a white crystalline solid is formed, but this decomposes again when the pressure is reduced below a certain amount (Cailletet a. Bordet, *C. R.* 95, 58; *v.* PHOSPHONIUM COMPOUNDS, p. 123).—3. White compounds, easily decomposed on removing pressure, are said to be formed by compressing PH_3 with *carbon dioxide*, and with *carbon disulphide*, in presence of water (C. a. B., *l.c.*).—4. A solution of *cuprous chloride* in HClAq absorbs PH_3 rapidly; a white crystalline mass of $Cu_2Cl_2.2PH_3$ is formed, but this liquefies as more PH_3 is passed in (? with formation of $Cu_2Cl_2.4PH_3$); the crystals $Cu_2Cl_2.2PH_3$ are decomposed by warming, or by addition of water, to PH_3, HCl, and Cu_3P; the liquid compound loses PH_3 in a stream of an indifferent gas, with production of the crystalline compound (*v.* Riban, *Bl.* [2] 34, 385). This behaviour of PH_3 towards Cu_2Cl_2 gives a method for preparing pure PH_3, and also for estimating PH_3 in a mixture of gases.

Phosphorus dihydride PH_2 or P_2H_4 (*Liquid phosphoretted hydrogen*). Mol. w. said to be 65·92, corresponding with V.D. c. 33, but no details given (Croullebois, *C. R.* 78, 496). Gattermann a. Hausknecht (*B.* 23, 1174) failed to determine V.D. as the compound always decomposed. A spontaneously inflammable gas containing P and H was obtained by Gengembre in 1783 (*Crell's Ann.* 1789. 450). The fact that this gas lost its inflammability by standing over air containing water was explained by Dumas (*A. Ch.* [2] 31, 113) by supposing that the gas was a mixture of two hydrides of P, one only of which was spontaneously inflammable; to one of these Dumas gave the formula PH_2 and to the other the formula PH_3. In 1832 H. Rose (*P.* 6, 199; 8, 191) thought that the two gases had the same composition, but were isomeric one with the other. After Graham (*P. M.* 5, 401) had examined the conditions under which spontaneous inflammability was removed from or bestowed on the gas, Le Verrier (*A. Ch.* [2] 60, 174) came to the conclusion that the gas consisted chiefly of PH_3, but that it contained also a very inflammable compound PH_2, which was decomposed by light into PH_3 and a solid hydride PH. In 1845 P. Thénard made a fuller study of the subject (*A. Ch.* [3] 14, 5); he showed that spontaneously inflammable phosphoretted hydrogen, when passed through a tube cooled to under 10°, deposited a liquid having the composition PH_2, which liquid was extremely inflammable, and that this liquid decomposed in light into gaseous PH_3 and a solid to which he gave the formula P_2H. In 1874 Croullebois said that the V.D. of the liquid hydride corresponds with the formula P_2H_4, but no details were given (*C. R.* 78, 496); in 1890 Gattermann a. Hausknecht attempted to determine V.D., but found that the compound decomposed (*B.* 23, 1174).

Preparation.—Impure Ca phosphide is prepared by heating dry CaO to bright redness in a crucible, and adding dried P little by little, the lid being replaced after each addition of P. The crucible should be arranged so that the P is brought under the strongly-heated CaO; this may be done by placing a few pieces of P in a crucible, filling up with dry CaO, covering tightly (but leaving one small hole), placing the crucible in a furnace arranged so that the lower part of the crucible projects downwards through the bottom of the furnace, heating the upper part of the crucible to bright redness, and then warming the lower part so as to vapourise the P. Small quantities are prepared by placing a dry piece of P in the closed end of a tube of hard glass, partly filling the tube with dry CaO, arranged so that there is a little space between the CaO and the P, placing the tube in a combustion furnace, heating the CaO strongly, and then warming the P. The CaO is transformed into a mixture of Ca phosphide and phosphate; the phosphide is nearly black; the unchanged CaO is picked out when the action is over, and the phosphide is at once placed in a stoppered bottle. (For modification of process *v.* Gattermann a. Hausknecht, *B.* 23, 1174.) A three-necked bottle of about 2 litres capacity is filled three-quarters with water; one of the necks carries the tube from a H apparatus, which tube dips considerably under the water, the middle neck carries a piece of tubing about 15 mm. internal diameter, dipping 2 or 3 cm. under the water, and the third neck carries an exit tube in communication with a condenser; between the condenser and the three-necked bottle is placed a test tube, to collect part of the water vapour coming over. The condenser consists of a tube about 100 mm. long and 30 mm. diameter, narrowed so that the lower end forms a tube about 40 mm. long by 12 mm. wide; this condenser is closed by a cork through which pass the entrance tube from the three-necked bottle and an exit tube, which is bent downwards and dips under the surface of water; these two tubes are cut off obliquely just below the cork. The condenser is placed in a deep vessel full of cold water which contains sufficient ice to keep the temperature at 0°. H is passed through the apparatus until all the air is driven out, the three-necked bottle is placed in a water-bath until the contents are warmed to 60°, and Ca phosphide, in pieces the size of peas, is dropped down the wide tube in portions about 2 g. at a time and at a rate such that 50 g. are added in 15 to 20 minutes. Gaseous P hydride passes off and bubbles up through the water, and the liquid hydride collects in the condenser, about 1-2 c.c. being obtained for 50 g. Ca phosphide used (Hofmann, *B.* 7, 531; Gattermann a. Hausknecht, *B.* 23, 1174; the many precautions to be taken in working with this compound are described by G. a. H.).

Properties and Reactions.—A colourless, highly refractive liquid; insol. in water; burns in air, with bright flame to P_2O_5 and H_2O; does not solidify at −10°; boils 57°-58° at 735 mm. (G. a. H., *l.c.*). S. G. 1·007 to 1·016 (G. a. H.). Decomposed by light into PH_3 and solid P_2H; the liquid may be kept for a short time in sealed tubes, but decomposition soon begins, and the tubes explode violently (G. a. H.). The same decomposition is effected by conc. HClAq, air mixed with CO_2, &c. Passage of the gas prepared as described above through a little conc. HClAq removes every trace of PH_2, and hence causes the gas which issues to be non-inflammable. If CO_2 is passed through the U-tube containing liquid PH_2 a nearly invisible greenish light appears at the end of the tube; this flame is not hot enough to ignite a candle (*v.* Hofmann, *B.* 7, 531; Thénard, *A. Ch.* [8] 14, 5; Bonet a. Bonfil, *J. pr.* 55, 247; Gattermann a. Hausknecht, *B.* 23, 1174). The composition of PH_2 was determined by Thénard by decomposing a known quantity by direct sunlight in a graduated tube filled with Hg: 100 parts liquid phosphide gave 61·8 parts gaseous PH_3 and 38·2 parts solid P_2H; *i.e.* 1 molecule P_2H was produced for 3 mols. PH_3, hence the equation $5PH_2 = P_2H + 3PH_3$. This equation was confirmed by G. a. H., who made also direct estimation of H by burning with $PbCrO_4$ in a current of CO_2 (*B.* 23, 1174).

Diphosphorus hydride P_2H or P_4H_2. Mol. w. unknown. H. F. $[P^2,H] = 17,700$ (Ogier, *C. R.* 89, 707).

Formation.—1. By decomposing phosphide of Ca or K (Magnus, *P.* 17, 527) by HClAq.—2. By the action of light, HClAq, Cl (Le Verrier, *A. Ch.* [2] 60, 174), and various other reagents, on PH_2.—3. By the decomposition of PI_2 by water (Rüdorff, *P.* 128, 473). Hittorf (*P.* 126, 193) obtained only amorphous P by this process.

Preparation. — A two-necked bottle is arranged with an exit tube dipping under water, and a wide entrance tube, down which is passed the delivery tube of a H-apparatus; conc. HClAq is placed in the bottle, H is passed through until all air is driven out, the H apparatus is removed, and small pieces of freshly-prepared Ca phosphide (for preparation *v. Preparation of phosphorus dihydride*, p. 137) are dropped slowly into the bottle. The P_2H which forms in the bottle is rapidly washed with cold water, and dried *in vacuo* (P. Thénard, *A. Ch.* [3] 14, 5).

Properties.—A yellow flocculent powder, which becomes orange-yellow in light; tasteless and odourless. When dry may be heated to c. 200° before taking fire; ignited by a blow of a hammer.

Reactions.—1. Ignited by *heating in air* to c. 200°; also by a blow of a hammer.—2. Slowly decomposed in *moist air*, especially if in sunlight, to P_2O_5 and H.—3. *Distillation in hydrogen* produces PH_3 (Thénard, *l.c.*).—4. *Chlorine* forms PCl_5 and HCl.—5. Dissolves in dilute *nitric acid*; oxidised with ignition by conc. HNO_3Aq.—6. *Alcoholic solution of potash* produces PH_3 and H; addition of water to the reddish solution ppts. yellow flocks of ? amorphous P or a lower oxide of P.—7. Explodes when mixed with *potassium chlorate*, *silver oxide*, *mercuric oxide*, or *cupric oxide*, and struck or warmed. – 8. Ppts. metallic phosphides from solutions of *salts of many heavy metals* (Le Verrier, *l.c.*).

Determination of composition.—The quantity of P in the solid hydride was determined by Thénard by heating with a weighed quantity of PbO, and weighing the mixture of PbO and Pb phosphate thus produced; the H was determined by decomposing by red-hot Cu, and collecting the H set free. Rüdorff decomposed the hydride by heat, and collected and analysed the mixture of PH_3 and H thus formed; he also oxidised the compound by HNO_3Aq, and estimated P as Pb phosphate.

Phosphorus, iodides of. P and I combine directly, even at −24°; two iodides, PI_2 and PI_3, have been isolated, and the existence of a third, PI_5, is probable.

Phosphorus di-iodide PI_2 or P_2I_4. Mol. w. not known. H.F. $[P,I^2] = 9,880$ from solid P and I; 20,680 from solid P and gaseous I (Ogier, *C. R.* 92, 83).

Formation.—1. By adding I to P Combination occurs even at −24°, with production of much heat, and ignition of the excess of P if air is admitted; amorphous P is produced besides PI_3 (*v.* Wurtz, *A. Ch.* [3] 42, 129).—2. By the reaction of I with PH_3; also of I in acetic acid on PCl_3 (Hofmann, *A.* 103, 305; Ritter, *A.* 95, 210).

Preparation.—One part by weight of P is dissolved in CS_2, and $8\frac{1}{5}$ parts of I are added little by little. When the colour of the dark brownish-red liquid thus produced has changed to orange it is cooled to 0° for some hours, when the vessel becomes filled with crystals; the crystals are freed from CS_2 by heating in a water-bath, while a stream of dry air is passed over them (Corenwinder, *A. Ch.* [3] 30, 242). The crystals may also be obtained by evaporating the solution in CS_2 in a stream of CO_2 (Berthelot a. Luca, *C. R.* 39, 748). Corenwinder says that from 2 to 3 g. P, and 60 to 75 c.c. CS_2, are convenient quantities to use.

Properties and Reactions.—Large orange-coloured prisms, melting at 110° (Corenwinder, *l.c.*). Heated in O gives P_2O_5 and I (Berthelot, *C. R.* 86, 628, 787, 859, 920; 87, 575, 667). Decomposed by H_2O to H_3PO_3Aq, PH_3, HIAq, and a yellow flocculent solid supposed to be amorphous P (Hittorf, *P.* 126, 193), regarded by Rüdorff as solid P_4H_2 (*P.* 128, 473), and said by Gautier (*C. R.* 76, 49, 173) to be P_5H_3O.

Phosphorus tri-iodide PI_3 (*Phosphorous iodide*). Mol. w. 410·55. H.F. $[P,I^3] = 10,900$ (Ogier, *C. R.* 92, 83). This compound is obtained in large red prisms by dissolving one part of P in CS_2, adding a solution of $12\frac{1}{4}$ parts of I in CS_2, concentrating much out of contact with air, and then placing in a freezing mixture. As the crystals are very sol. CS_2, they should be at once freed from mother-liquor, and dried in a stream of dry air at c. 50°. The crystals melt at 55°, and boil at a higher temperature, with evolution of I. PI_3 is very deliquescent; moist air decomposes it at once to H_3PO_3Aq and HIAq (Corenwinder, *A. Ch.* [3] 30, 242).

Phosphorus penta-iodide PI_5 (*Phosphoric iodide*). Isolation doubtful. Hampton (*C. N.* 42, 180) obtained a dark-crimson, very deliquescent solid, giving numbers on analysis agreeing with 80 p.c. PI_5 + 20 p.c. PI_3, by dissolving P in a little CS_2 in a stream of pure dry N, adding rather more than enough I to form PI_5, distilling off CS_2 (in a N stream) at 45° under reduced pressure, and then warming to 50°; at 55°, under the reduced pressure, I began to sublime.

Phosphorus, iodo-chloride of, PI_2Cl_3. Produced by adding much I to a little PCl_3, allowing to stand in moist air for some days, drying the crystals in a stream of air, dissolving in CS_2, and crystallising: large, red, six-sided crystals, very hygroscopic; decomposed by water to H_3PO_3Aq, HClAq, and HIAq (Moot, *B.* 13, 2029).

Phosphorus, nitride of. No compound of P and N has been isolated with certainty. A substance supposed to be a nitride by Rose (*P.* 24, 308; 28, 529) and Wöhler a. Liebig (*A.* 11, 139) was found to contain H. Briegleb a. Geuther (*A.* 123, 236) think that a compound P_3N_5 is perhaps produced by the reaction of PCl_5 on hot Mg_3N_2 in an atmosphere of N.

Phosphorus, oxides of. P and O combine very readily, with production of much heat; four compounds are produced according to the conditions: P_4O, P_2O_3, P_2O_4, and P_2O_5; the V.D.

of the second of these shows that its mol. formula as a gas is P_4O_6. The oxides P_2O_3 and P_2O_5 are anhydrides; the former reacts with water to produce the acid H_3PO_3, and the latter to produce three acids, HPO_3, H_3PO_4, and $H_4P_2O_7$; the oxide P_2O_4 is not the anhydride of a corresponding acid—with water it produces the two acids H_3PO_3 and H_3PO_4.

The only oxide formed when P glows in air at ordinary temperature is P_2O_5, but P_2O_3 is formed by drawing air over P without the latter glowing (Thorpe a. Tutton, *C. J.* 57, 573); at 50°-60° small quantities of P_2O_3 are produced, and this oxide is produced in larger quantities when the P is actually ignited; at moderately high temperatures and with a limited supply of air the oxide P_4O is formed in addition to P_2O_5 and P_2O_3. If the products of the slow burning of P in dry air are heated together in CO_2, the oxide P_2O_4 is formed, along with some P_4O. The products of burning P in a limited supply of dry air generally contain small quantities of P; this may be removed by sucking the products through a tube heated by steam (Thorpe a. Tutton, *C. J.* 49, 833).

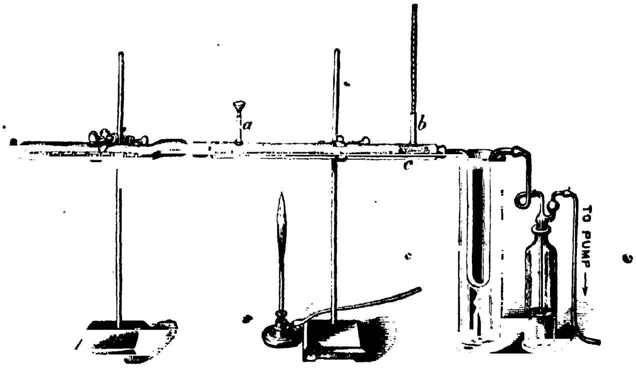
PHOSPHORUS SUBOXIDE P_4O. Mol. w. uncertain. Some doubt still remains concerning the composition of the lowest oxide of P; but the evidence is in favour of the existence of a definite oxide P_4O. Le Verrier (*A.* 27, 167) obtained a yellowish solid by exposing P in PCl_3 or in ether to air, warming the solid thus formed with water, and drying over H_2SO_4. A similar product was obtained by the incomplete combustion of P in air, or by the action on P of such oxidisers as iodic or periodic acid in presence of water (*v. Gm.-K.* i. 2, 107). This substance was generally looked on as an oxide of P; Le Verrier gave it the formula P_4O; Schrötter (*W. A. B.* 8, 246) thought it was only a mixture of ordinary and amorphous P. Reinitzer a. Goldschmidt (*B.* 13, 845) obtained the oxide P_4O by heating $POCl_3$ with P to 200°-250°, also by heating $POCl_3$ with Zn, Mg, or Al at 100°. Thorpe a. Tutton (*C. J.* 49, 833) found that P_4O is one of the products of burning P in a limited supply of air at moderately high temperatures, and that it is formed when the products of the slow burning of P in dry air are heated to c. 300° in CO_2. The experiments of R. a. G. indicate the existence of two varieties of P_4O; one of these reacts with hot alkali solutions, evolving PH_3, and reduces salts of Au and Ag and mercurous salts, and the other is not acted on by alkalis, and does not reduce salts of Au, Ag, or Hg.

Preparation and Properties of P_4O *which reduces salts of* Ag, Au, and Hg.—1. Thin plates of pure Zn are heated with $POCl_3$ in a sealed tube in a water-bath at 100° for some hours, the liquid, with suspended solid matter, is poured off, the solid is allowed to settle and the liquid is decanted off; the solid is heated as before for some time with $POCl_3$ (to remove any Zn present), the liquid is poured off, the solid is washed with $CHCl_3$ to remove $POCl_3$, then with HClAq, and finally with water; the solid is then dried for some days *in vacuo* (Reinitzer a. Goldschmidt, *B.* 13, 849); the other products of the reaction are $ZnCl_2$ and $Zn2PO_3$. As thus prepared P_4O is an orange-red powder. It very obstinately retains water, the sample made by R. a. G. contained c. 8 p.c. water, but the P and O were in the ratio P_4O. This oxide in moist air evolves PH_3; it reacts with boiling alkali solutions forming PH_3 and alkali phosphite and phosphate; solutions of salts of Au and Ag, and mercurous salts, are reduced with ppn. of the metals; heated in H, P is given off, and P_2O_5 remains.—2. PCl_3 is placed in an open flask, of c. 1 litre capacity, containing a layer about 2 cm. thick of P in small pieces; the PCl_3 just covers the P; after c. 2 days the PCl_3 is poured off, the pieces of P and the adhering yellow film are loosened from the flask, and allowed to fall slowly into cold water (if water is added in quantity, heat is produced, and the products of the slow oxidation of P are decomposed). After a little, the water is filtered from suspended P, and the clear yellow filtrate is heated to 80°, when a very finely divided yellow solid settles down; this solid is washed with warm water in a filter, removed from the filter while moist, and placed in a basin, over H_2SO_4 *in vacuo*. Le Verrier's P_4O was tasteless and odourless, did not change in dry air or O, but in moist air it gave off PH_3; it was decomposed somewhat above 360°, giving off P and leaving P_2O_5; oxidised by Cl to PCl_5 and P_2O_5; heated with conc. H_2SO_4, gave SO_2; unacted on by HClAq; oxidised and dissolved by HNO_3Aq; exploded with $KClO_3$; readily combined with H_2O to form $P_4O.H_2O$. The oxide obtained by Thorpe a. Tutton (*C. J.* 49, 833) was formed by slowly burning P in dry air, transferring the products to a tube filled with CO_2, exhausting by a Sprengel pump, and heating to 290°; as the oxide is described as orange-red, it was probably the form of P_4O which reduces salts of Au, Ag, and Hg.

Preparation and Properties of P_4O *which does not reduce salts of* Ag, Au, *and* Hg.—$POCl_3$ is heated with an excess of P in a sealed tube to 200°-250°; the sides of the tube become covered with a scarlet-coloured solid, which is washed with CS_2 (to remove P) and dried *in vacuo* (R. a. G., *l.c.*; the other products are PCl_3, $P_2O_3Cl_4$ and a little P_2O_5). As thus prepared, P_4O is a scarlet-red solid; S.G. 1·88; it is not acted on by water or alkali solutions, and it does not reduce salts of Ag, Au, or Hg. This form of P_4O seems to have been obtained by Pelouze (*A.* 3, 52) by burning P in O; and by Le Verrier (*A.* 27, 175) by burning P in a thin layer on a porcelain plate, washing with water to remove oxyacids, and boiling with PCl_3 to remove P.

PHOSPHOROUS OXIDE P_4O_6. (*Phosphorus trioxide. Phosphorous anhydride.*) Mol. w. 219·6; same in solution in C_6H_6 (Thorpe a. Tutton, *C. J.* 57, 545). Melts at 22·5°; boils at 173·1° (T. a. T.). S.G. $\frac{21°}{4°}$ liquid P_4O_6 1·9431; solid P_4O_6 at $\frac{21°}{4°}$ c. 2·135. S.G. at b.p. = 1·6897 (T. a. T.). V.D. 111·9. S.V. 130·2 (T. a. T.). $\mu_A = 1·5311$; $\frac{\text{Mol. w.}}{\text{S.G.}} \times \mu = 60·5$ (T. a. T.). Mol. w. $\frac{\mu_H - \mu_A}{\text{S.G.}} = 4·17$. M.M. 9·962.

Preparation.—A piece of combustion-tubing about 40 mm. bore is drawn into the shape shown in the figure on following page, and is fitted by a good cork into a brass tube, which is surrounded by a wider tube of brass; water is introduced at *a* between the brass tubes, and a thermometer is placed at *b*. A loose-plug of glass-wool is placed in the inner brass tube at *c*. The U-shaped condenser is of rather narrow bore, the limbs are about 800 mm. long, a small bottle is attached to the vertical piece at the bottom of the condenser, which is itself connected with the inner brass tube by a good cork; the condenser and small bottle are surrounded by ice and salt. The bottle between the condenser and the pump contains oil of vitriol. Two sticks of P are dried between filter-paper, cut into pieces c. 25 mm. long, and placed in the combustion tube, which is then narrowed at the open end and fitted into the brass tube; the pump is set in action, and the P is ignited by holding a small flame beneath the open end of the combustion-tube. Air is sucked over the P as rapidly as possible; if the combustion is too local, much P_2O_5 is formed; considerable quantities of red P_4O are formed near the burning P. When the P has burnt for c. 15 mins. the water in the brass tube is heated to c. 50°, at which temperature it is kept till near the end of the experiment, when it is raised to 60°. P_4O_6 begins to collect in the condenser about 30 mins. after starting the combustion; if the glass-wool is packed properly (it should not be too tight) no P_2O_5 passes into the condenser, and if the temperature of the water does not exceed 60° only very small quantities of P pass over. The process is stopped when c. $\frac{4}{5}$ths of the P is burnt, else the P_4O_6 may be oxidised. The condenser is removed, the P_4O_6 is melted by the heat of the hand, and run down into the little bottle, from which it may be transferred to another bottle which has been filled with dry CO_2; this bottle should have a very tightly-fitting stopper, and should be kept in the dark in an atmosphere of CO_2 (T. a. T., *l.c.*).



Properties.—A white snow-like solid, with an alliaceous odour resembling that of P; when melted and cooled slowly crystallises in long thin prisms, probably monoclinic; melts at 22·5° to a clear, colourless, very mobile liquid, which solidifies again at 21°; the liquid may be cooled in a narrow tube several degrees below m.p. without solidifying; boils at 173·1° in CO_2 or N. Can be gasified in Hofmann's V.D. apparatus at 132°. Mol. w. as gas, and also in solution in C_6H_6 (determined by cryoscopic method), corresponds with P_4O_6. Soluble without change in C_6H_6, CS_2, $CHCl_3$, and ether. Heated to c. 200° in sealed tube begins to decompose to P_2O_4 and P. Decomposed by light, with separation of red P. T. a. T. (*C. J.* 59, 1019) several times obtained clear, transparent, perfectly-formed crystals of P_4O_6 by slow spontaneous sublimation *in vacuo*, which remained unchanged for many days, although exposed to light. Spec. volume at b.p. = 130·2. (For details of thermal expansion and S.G. at b.p. *v.* T. a. T., *C. J.* 57, 545.) Reacts slowly with cold water, forming H_3PO_3Aq; with boiling water reaction is violent, PH_3 is evolved, and red P, or perhaps P_4O, and H_3PO_4Aq are formed. Oxidises to P_2O_5 by exposure to air or O; if temperature is raised the P_4O_6 ignites and may explode. P_4O_6 has a well-marked physiological action; the action of P may be due to P_4O_6, formed by the air oxidising the P (T. a. T., *l.c.* p. 573).

Reactions.—1. *Heat* decomposes P_4O_6, forming P_2O_4 and P (? P_4O); the action begins at c. 210° in a sealed tube, and the whole of the P_4O_6 is decomposed at 440° (T. a. T., p. 552).—2. Rapidly acted on by *light*, becoming yellow and then dark-red (T. a. T., p. 553). The action of light separates red P; the amount obtained after several months' exposure does not exceed 1 p.c. (T. a. T., *C. J.* 59, 1019). By exposing P_4O_6 to light for some months in a sealed tube filled with dry CO_2, then melting, filtering through glass-wool, and repeating this process several times, T. a. T. eventually obtained P_4O_6 which remained perfectly clear and colourless after twelve months' exposure (*l.c.*, p. 1023).—3. Oxidises to P_2O_5 in *air* or *oxygen*; when quite free from P, the oxide is not spontaneously inflammable. Under reduced pressure in O the P_4O_6 glows; on raising temperature to c. 70° at ordinary pressure the glow gives place to flame. Combination occurs between vapour of P_4O_6 and O; ozone is not formed. When P_4O_6 is thrown into O heated to 50°–60° ignition occurs with an intensely brilliant flame (T. a. T., *C. J.* 57, 569).—4. Glows continuously, and oxidises to P_2O_5, when a stream of *ozonised oxygen* is passed over it.—5. Ignites in *chlorine*, burning with a greenish flame; when surrounded by ice and exposed to slow stream of Cl a liquid is formed, which on distillation gives $POCl_3$, while PO_2Cl (?) remains (T. a. T., *C. J.* 57, 572).—6. Reacts violently with liquid *bromine*; using Br vapour at ordinary temperature, T. a. T. (*C. J.* 59, 1020) obtained PBr_3 and P_2O_5, and on then heating $POBr_3$ and PO_2Br (?) were formed.—7. *Iodine* reacts slowly; by heating with I and CS_2 under pressure, P_2O_5 and P_2I_4 are produced (T. a. T., *l.c.*, p. 1021). 8. Heated with *sulphur*, in CO_2 or N, two layers of liquid are formed; at 160° there is violent reaction, and solid $P_4O_6S_4$ is produced (*v.* PHOSPHORUS, SULPHOXIDE OF, p. 149; T. a. T., *l.c.*, p. 1022).—9. Seems to form a Se compound analogous to $P_4O_6S_4$ by heating with *selenium* (T. a. T., *l.c.*, p. 1026).—10. Dissolves very slowly in *water*, forming H_3PO_3Aq (T. a. T., *C. J.* 57, 567); $P_4O_6 + 6H_2O + Aq = 4H_3PO_3Aq$. The action of *hot water* is very energetic; red P, or red P_4O, is ppd., inflammable hydride of P is evolved, and H_3PO_4Aq is formed; if the quantity of P_4O_6 exceeds 2 g. the action of hot water is violently explosive.—11. Dry *hydrogen chloride* is rapidly absorbed; PCl_3 is formed along with H_3PO_3, H_3PO_4, and yellow P (T. a. T., *C. J.* 59, 1022).—12. Conc. *sulphuric acid* reacts violently, forming H_3PO_4 and SO_2; if 1 g. or more P_4O_6 is used, the mass ignites (T. a. T., *l.c.* p. 1026).—13. P_4O_6 is rapidly oxidised to P_2O_5 by *sulphur trioxide*, which is reduced to SO_2; no compound could be obtained (T. a. T., *l.c.* p. 1026). According to Adie (*C. J.* 59, 230), if a little water is present, P_4O_6 and SO_3 form an unstable compound $H_3PO_4.3SO_3$.—14. *Nitrogen tetroxide* seems to react like SO_3, forming P_2O_5 and N_2O_3 or NO (T. a. T., *l.c.* p. 1028).—15. *Phosphorus pentachloride* produces PCl_3 and $POCl_3$; *phosphorus trichloride* reacts at c. 180° in a sealed tube, forming a mixture of P_2O_5, PCl_5, and red P (T. a. T., *l.c.* p. 1028).—16. *Sulphur chloride* reacts violently, producing $POCl_3$, $PSCl_3$, SO_2, and S (T. a. T., *l.c.* p. 1026).—17. *Ammonia* reacts with some violence, probably producing $OH.P.(NH_2)_2$ (*v.* PHOSPHAMIDES, p. 105).—18. *Cold dilute caustic soda*, or *caustic potash solution*, slowly dissolves P_4O_6, forming a solution of Na or K phosphite; *cold conc.* or *hot dilute solution of soda or potash* produces red P (or P_4O ?) and alkali phosphate, and evolves inflammable hydride of P.—19. Ignites in contact with *absolute alcohol*; by allowing the alcohol to drop slowly on to cooled P_4O_6 the acid $P(OEt)_2OH$ is formed (T. a. T., *C. J.* 57, 569). P_4O_6 seems *not* to react with H, PH_3, CO, CO_2, SO_2, N, NO, CN, or C_2H_4 (T. a. T., *C. J.* 59, 1029).

PHOSPHORUS TETROXIDE P_2O_4 (*Phosphoroso-phosphoric oxide. Hypophosphoric oxide*). Mol. w. not determined; corresponding sulphide has mol. w. P_3S_6. Hautefeuille a. Perrey (*C. R.* 99, 33) noticed that a crystalline sublimate is obtained by heating the products of the combustion of P; Thorpe a. Tutton (*C. J.* 49, 833) proved that this sublimate is a definite oxide P_2O_4. Concerning the combustion of P in air *v.* pp. 128 and 139.

Preparation.—P is burnt slowly in a stream of air dried by H_2SO_4 and P_2O_5; the products are collected in a glass tube, surrounded by an outer tube filled with steam, and are then quickly transferred to a tube filled with dry CO_2, the tube is drawn out, exhausted by a Sprengel pump (care being taken to prevent entrance of moisture), and sealed; at c. 290° the white mass becomes orange-coloured, and then red, and a white crystalline sublimate of P_2O_4 is formed, leaving P_2O_3 and P_4O in the lower part of the tube. T. a. T. (p. 838) think that the P_2O_4 is derived from the P_2O_3, thus $7P_2O_3 = 5P_2O_4 + P_4O$; that P_2O_4 is formed by heating P_2O_3 out of contact with O is shown by T. a. T. (*C. J.* 57, 552).

Properties and Reactions.—Colourless crystals, probably orthorhombic; do not melt at 100°. Volatilises at c. 180°. Very deliquescent, forming H_3PO_3Aq and H_3PO_4Aq; from this reaction T. a. T. conclude that P_2O_4 is not the anhydride of $H_4P_2O_6$, as an aqueous solution of this acid does not behave like a mixture of H_3PO_3 and H_3PO_4, and can be boiled without change. Solution of P_2O_4 in water reduces $AgNO_3Aq$ to Ag, and $HgCl_2Aq$ to HgCl; $KMnO_4Aq$ is very slowly decolourised; 'magnesia mixture' gives an immediate pp., and after standing some time the filtrate gives a large pp., with NH_4 molybdate after heating with HNO_3Aq.

PHOSPHORIC OXIDE P_2O_5 (*Phosphoric anhydride. Phosphorus pentoxide*). Formula probably molecular, from analogy of P_2S_5. S.G. 2·387 (Brisson, *Pesanteur spécifique des Corps* [Paris, 1787]). H.F. $[P^2,O^5] = 369,900$; $[P^2O^5,Aq] = 35,600$ (*Th.* 2, 409).

Formation.—1. This oxide is formed by burning P in a large excess of air; concerning the combustion of P in air *v.* pp. 128 and 139.—2. It is also formed by burning P in such gaseous O compounds as NO, NO_2, ClO_2.—3. By distilling $P_2O_3Cl_4$.

Preparation.—A large glass balloon with a wide opening and two side necks is thoroughly dried; through a cork in the wide opening passes a piece of wide tubing, which reaches to about the centre of the balloon, and from the lower end of this tube a small porcelain basin is suspended by Pt wires; one of the side necks is connected with U-tubes containing pumice soaked in H_2SO_4, and the other side neck is connected with a wide-mouthed perfectly dry bottle, which is again in connection with a water-pump, a bottle with H_2SO_4 being placed between the pump and the wide-mouthed bottle. A small piece of well-dried P is placed in the little basin, and is ignited by passing a hot wire down the glass tube, the mouth of which is then closed by a good cork; a rapid stream of air is sucked through the apparatus; the P is burnt to P_2O_5, part of which collects on the bottom of the balloon and part passes into the bottle attached to the side neck. When the P is burnt another small piece is dropped down the glass tube into the little basin, and the process is continued. When sufficient P_2O_5 has collected in the bottle this is closed by a well-fitting stopper (Delalande, *A. Ch.* [2] 76, 117). For other forms of apparatus *v.* Marchand, *J. pr.* 16, 373; Mohr, *Gm.-K.* i. 2, 120. Grabowski (*A.* 136, 119) has described a vessel of tinplate for preparing large quantities of P_2O_5.

Shenstone says that P_2O_5, prepared by the ordinary process, has generally reducing powers, and is not, therefore, trustworthy as a drying agent. S. recommends to heat for some days at c. 300° in a *very slow* stream of dry O; then to

**heat at 300° in a more liberal, but still limited, supply of dry O until the reddish colour produced by the first heating has disappeared; then to heat at 300° in a more rapid stream of dry O so long as sublimation occurs; and finally to sublime, fractionally, in a current of dry O, from retorts of hard glass into receivers of the same material. The first portions of the sublimate should be rejected. The whole of these processes may be done in glass vessels. The retorts used in the final sublimation may be heated in a combustion furnace (*private communication*).

Hautefeuille a. Perrey (*C. R.* 99, 33) say that P_2O_5 can be obtained in three forms: crystalline, amorphous and powdery, and glass-like. They say that when P is burnt in a glass tube in dry air, the crystalline form of P_2O_5 is deposited on the colder part of the tube, the amorphous powdery form on the hotter part, and the vitreous form on that part of the tube which is heated to redness. These authors assert that crystalline P_2O_5 is obtained free from the other forms by distilling the products of the burning of P; that heating the crystals in vapour of S produces the powdery amorphous form; that the vitreous variety is formed by heating either of the others to low redness; and that this vitreous form yields crystalline P_2O_5 when sublimed at a red heat. Considering the facts brought to light by the work of Thorpe a. Tutton on the combustion of P (*C. J.* 49, 833; 57, 545; *v.* beginning of this article, p. 139), the existence of various modifications of P_2O_5 must be looked on as very doubtful. T. a. T. (*C. J* 49, 838) think it very likely that the crystalline form of P_2O_5 obtained by H. a. P. was P_2O_4; and it is probable that the differences in the properties of the powdery and vitreous P_2O_5 were due to admixture with P_2O_3. No analytical data are given by H. a. P. Shenstone (*priv. comm.*) says that P_2O_5 purified by his method is crystalline, but becomes amorphous when suddenly heated.

Properties.—A snow-white, amorphous, inodorous, very deliquescent, solid. Melts and sublimes below red heat (Lautermann, *A.* 113, 240); according to Davy (*A. Ch.* [2] 10, 218) volatile only at white heat. Absorbs water very rapidly; hence is used as a very efficacious drying agent. P_2O_5 is the anhydride of three phosphoric acids: HPO_3, H_3PO_4, and $H_4P_2O_7$. Dry P_2O_5 does not change the colour of dry litmus paper. Commercial P_2O_5 often contains traces of P, which cause it to redden in light, and also traces of As_2O_3 derived from the impure P used; it generally has more or less marked reducing powers.

Reactions. — 1. *Water* produces HPO_3; $H_4P_2O_7$ is formed from HPO_3 by the long-continued action of moist air; and H_3PO_4 is produced by continued heating of HPO_3Aq.—2. P_2O_5 removes H_2O from many *compounds which contain water or the elements of water*; *e.g.* it produces anhydrides when heated with several acids, H_2SO_4 gives SO_3, HNO_3 gives N_2O_5, and hydrocarbons are often formed by heating P_2O_5 with compounds of C, H, and O.—3. Heated with several *metals*, *e.g.* Fe, K, Na, Zn, metallic oxide, phosphide, and phosphate are formed.—4. *Salts of acids the anhydrides of which are volatile* are decomposed by heating with P_2O_5, with formation of phosphates and volatilisation of the anhydrides (Odling, *P. M.* [4] 18, 168).—5. $POCl_3$ is formed by heating P_2O_5 with *sodium chloride*, or with *phosphorus pentachloride*.—6. Heated with *phosphoryl chloride*, $P_2O_3Cl_4$ and $P_7O_{15}Cl_5$ (which may be a mixture) are formed (Huntly, *C. J.* 59, 202).—7. *Ammonia* produces $PONH_2(OH)_2$ and $P_2O_3(NH_2)_2(OH)_2$ (*v.* PHOSPHAMIC ACIDS, p. 105).—8. Heated with *boron chloride* to 200° for 2–3 days, $P_2O_5.B_2O_3$ and $POCl_3.BCl_3$ are formed (Gustavson, *B.* 4, 976). $P_2O_5.B_2O_3$ is also formed by heating P_2O_5 with *boric acid.*

Combinations.—1. With *water* (*v. supra, Reactions*, No. 1).—2. With *sulphur trioxide* to form $P_2O_5.3SO_3$, decomposed at 30° (Weber, *B.* 20, 86).—3. With *silica and water* to form $P_2O_5.SiO_2.4H_2O$; formed by heating conc. H_3PO_4Aq with silica (Hautefeuille a. Margottet, *C. R.* 104, 156). Similar compounds with *oxides of titanium, zirconium*, and *tin* are described by H. a. M. (*C. R.* 102, 1017).

Phosphorus, oxyacids of. The three phosphoric acids are described in the article PHOSPHORIC ACIDS, p. 124, and the salts of those acids in the article PHOSPHATES, p. 106; the other oxyacids of P and their salts are described under PHOSPHORUS, OXYACIDS OF, AND THEIR SALTS, p. 149.

Phosphorus, oxybromide of, $POBr_3$ (*Phosphoryl tribromide*). Mol. w. 286·2. Melts at 55° (Baudrimont, *A. Ch.* [4] 2, 58); at 45°–46° (Ritter, *A.* 95, 210). Boils at 195° (Ritter, *l.c.*); at 193° (Gladstone, *P. M.* [3] 35, 345). V.D. 145·5. S.G. 2·822 (Ritter, *J.* 8, 301). H.F. $[P,O,Br^3] = 108,000$ from liquid Br; 120,000 from gaseous Br (Ogier, *C. R.* 92, 83).

Formation.—1. By the action of moist air or a very little H_2O on PBr_5 (Gladstone, *P. M.* [3] 35, 345).—2. By the action of oxalic or acetic acid on PBr_5 (Baudrimont, *A. Ch.* [4] 2, 58; Ritter, *A.* 95, 210).—3. By passing O into boiling PBr_3; explosions generally occur (Demole, *Bl.* [2] 34, 201).

Preparation.—To 137·5 parts PCl_3 are added 18 parts H_2O, and then 160 parts Br are added drop by drop, HBr and HCl are evolved, and $POCl_3$ and $POBr_3$ remain (part of the PCl_3 is decomposed to H_3PO_3 and HCl, and the H_3PO_3, Br, and remaining PCl_3 react, (?) thus $2PCl_3 + H_3PO_3 + 3Br_2 = 2POCl_3 + POBr_3 + 3HBr$); the liquid is distilled, the portion boiling above 150° being kept separate and surrounded by a freezing mixture till it solidifies (Geuther a. Michaelis, *J. Z.* 6, 242).

Properties and Reactions.—Large colourless plates, which melt and boil in dry air without decomposition; soluble in conc. H_2SO_4, reppd. by H_2O; soluble in $CHCl_3$, CS_2, ether, and turpentine. Decomposed rapidly by *water* to HBrAq and H_3PO_4Aq; *bromine chloride* forms $POBrCl_2$ or $POCl_3$, and Br, according to the quantity used (Geuther, *J. Z.* 10, 130); *hydrogen sulphide* probably forms $PSBr_3$; *chlorine* forms $POCl_3$ and Br; *bromine* seems to form an additive compound which separates into $POBr_3$ and Br on heating (Gladstone, *l.c.*); *tin* and *antimony* remove Br (Baudrimont, *l.c.*).

Phosphorus, oxybromochlorides of. Two of these compounds are known, but it is doubtful whether the second is a definite compound or a mixture of $POCl_3$ and $POBr_3$.

Phosphorus oxybromodichloride $POBrCl_2$. (*Phosphoryl bromodichloride*). Mol. w. 197·4. Melts at 11°; boils at 137·6 (Thorpe, *C. J.* 37, 348). S.G. $\frac{0^\circ}{4^\circ}$ 2·12065 (Thorpe, *l.c.*). A colourless liquid, which solidifies, when cooled below 0°, to large colourless tablets which melt at 11°; when repeatedly distilled, or more quickly when heated in a closed tube to c. 185°, decomposed to $POCl_3$ and $POBr_3$ (Chambon, *J. Z.* 10, 92); decomposed by H_2O to H_3PO_4Aq, HClAq, and HBrAq; with a little alcohol forms $POCl_2(OEt)$ and HBr. Prepared by the reaction of $POBr_3$ with BrCl in the ratio $POBr_3 : BrCl$ (Geuther, *J. Z.* 10, 130); by the action of PBr_5 on $P_2O_3Cl_4$ (G. a. Michaelis, *J. Z.* 7, 103). By reacting on $P.OEt.Cl_2$ with Br (Menschutkin, *A.* 139, 343); 80 g. Br are allowed to drop slowly into 74 g. $P.OEt.Cl_2$ kept well cooled and constantly shaken; the reaction is very violent; the $POBrCl_2$ is separated from the C_2H_5Br formed by fractionation (Thorpe, *C. J.* 37, 343). The $P.OEt.Cl_2$ is prepared by slowly dropping absolute alcohol into well-cooled PCl_3 in the ratio $C_2H_6O : PCl_3$, allowing to stand for some time, and fractionating; the boiling-point is 117°–118°.

Phosphorus oxydibromochloride $POBr_2Cl$ (*Phosphoryl dibromochloride*). By the reaction of $POBr_3$ and BrCl, in the ratio $POBr_3 : 2BrCl$, Geuther (*J. Z.* 10, 130) obtained a liquid boiling between 150° and 160°, and decomposing very easily by heat into $POCl_3$ and $POBr_3$; analyses agreed with the formula $POBr_2Cl$, but the liquid was possibly a mixture of $POCl_3$ and $POBr_3$ ($3POBr_2Cl = POCl_3 + 2POBr_3$).

Phosphorus, oxychlorides of. Two oxychlorides of P have been isolated, $POCl_3$ and $P_2O_3Cl_4$. A third substance obtained by Gustavson (*B.* 4, 853) by heating together P_2O_5 and $POCl_3$, and said by him to be PO_2Cl, is declared by Michaelis (*G. O.* [1881] 2, 396) not to be a definite compound, and this is confirmed by Huntly (*C. J.* 59, 202).

Phosphoryl chloride $POCl_3$. Mol. w. 153·3. Boils at 107·2° (Thorpe, *C. J.* 37, 337). Melts at −1·5° (Geuther a. Michaelis, *B.* 4, 769). S.G. $\frac{0^\circ}{4^\circ}$ 1·71163 (Thorpe, *l.c.*). V.D. at 150° = 77·2 (Cahours, *A. Ch.* [3] 20, 369). For expansion by heat *v.* Thorpe (*l.c.*). S.V. 101·4 (T., *l.c.*). H.F. $[P,O,Cl^3] = 145,960$; $[PCl^3,O] = 70,660$ (*Th.* 2, 325).

Formation.—1. By heating PCl_3 in air or O, or with ozone, SO_3, SO_2Cl_2, and various other oxidisers.—2. By strongly heating PCl_5 in O, or with SO_3, SO_2, B_2O_3, &c., or by decomposing by a little H_2O.—3. By distilling NaCl mixed with P_2O_5 (Kolbe a. Lautemann, *A.* 113, 240).—4. By passing CO and Cl over Ca_32PO_4 mixed with C and heated to redness (Riban, *C. R.* 95, 110; Oglialoro, *G.* 13, 328).—5. By heating PCl_5 with P_2O_5.—6. By the reaction of Cl with P_2O_3 (Thorpe a. Tutton, *C. J.* 57, 572).

Preparation.—An intimate mixture of 1 part P_2O_5 with 2·9 parts PCl_5 is distilled, and the product is again distilled, that boiling at 106°–108° being collected separately; the equation $P_2O_5 + 3PCl_5 = 5POCl_3$ is realised.

Properties.—A colourless, highly refractive, strongly smelling liquid, which fumes in the air; the fumes strongly affect the eyes and respiratory organs; solidifies at −10°, when touched with a glass rod, to long, colourless tablets, which melt again at −1·5° (Geuther a. Michaelis, *B.* 4, 769). $POCl_3$ does not conduct electricity even when heated (Buff, *A.* 110, 257).

Reactions.—1. *Water* reacts rapidly, forming HClAq and H_3PO_4Aq $[POCl^3,Aq] = 72,190$ (*Th.* 2, 325).—2. *Alcohol* produces HCl and $PO.OEt.Cl_2$.—3. *Sulphur trioxide* at 160° forms $P_2O_3Cl_4$ and P_2O_5 (Michaelis, *G. O.* 2, 393).—4. *Sulphuric acid* produces $SO_2.OH.Cl$, HCl, and HPO_3 (Michaelis, *l.c.*).—5. Most *organic acids* react similarly to H_2SO_4, producing acid chlorides; *e.g.* $C_2H_3O.OH$ forms $C_2H_3O.Cl$; *salts of organic acids* react similarly, forming acid chloride and metaphosphate.—6. *Sulphates* form SO_2Cl_2 and orthophosphates.—7. *Sulphites* are partially changed to SO_2, mixed with metallic chloride and phosphate (Divers a. Shimidzu, *C. J.* 47, 208).—8. *Nitrates* produce chlorides and P_2O_5 &c.; *nitrites* give chlorides and phosphates and NO_2 (D. a. S., *l.c.*).—9. $POCl_3$ separates I from *potassium iodide* (Schiff, *A.* 102, 181).—10. *Chromyl chloride* forms Cl, P_2O_5, $CrCl_3$, and Cr_2O_3 (Casselmann, *A.* 91, 241; 98, 213).—11. *Phosphorus pentasulphide* at 150° produces $PSCl_3$ and P_2O_5.—12. *Phosphorus pentoxide* reacts at c. 200°, forming $P_2O_3Cl_4$ and a substance $P_7O_{15}Cl_9$, which may prove to be a mixture (Huntly, *C. J.* 59, 202).—13. *Phosphorus* reacts at 200° to form P_4O, PCl_3, $P_2O_3Cl_4$, and a little P_2O_5 (Reinitzer a. Goldschmidt, *B.* 13, 845).—14. $POCl_3$ is reduced by heating in closed tubes with many finely divided *metals*, *e.g.* Ag, Hg, Fe, Cu, As (Pb is without action); the products are generally PCl_3 and P_2O_5, and oxide, chloride, or phosphate of the metal; sometimes $P_2O_3Cl_4$ is said to be formed (*v.* R. a. G., *l.c.*); Mg, Al, and Zn are said to form red P_4O (R. a. G., *l.c.*). Zinc-dust with a little $POCl_3$ forms Zn phosphide, which evolves inflammable P hydride on addition of a little water (Denigès, *Bl.* [3] 2, 787).—15. With *ammonia* forms various *phosphamic acids* (*q. v.*, p. 105), and also *phosphamides* (*q. v.*, p. 105).—16. *Boric oxide* heated with $POCl_3$ in a sealed tube to 150°–170° for 8 to 10 hours forms $P_2O_5.B_2O_3$ and $POCl_3.BCl_3$ (Gustavson, *B.* 4, 975).

Combinations.—1. With *ammonia* to form a compound not yet examined.—2. With several *metallic chlorides* to form double compounds, *e.g.* with $AlCl_3$, $MgCl_2$, and $SnCl_2$ (Casselmann, *A.* 91, 241; 98, 213). Some of these compounds may be vapourised in absence of moisture; they are decomposed by water.—3. With *boric chloride* to form $POCl_3.BCl_3$, by passing BCl_3 into $POCl_3$; also by heating $POCl_3$ with B_2O_3. This substance is decomposed by heat; with water it gives H_3PO_4Aq, H_3BO_3Aq, and HClAq (Gustavson, *B.* 4, 975).

Constitution of $POCl_3$.—Two isomeric forms of $POCl_3$ are possible: Cl_2POCl and Cl_3PO; but the compounds obtained by different methods are identical. Wichelhaus (*A. Suppl.* 6, 257) thought that $POCl_3$ must have the constitution Cl_2POCl, because of its formation from Cl_2POEt, in which the O atom is in direct union with the P atom ($Cl_2POEt + Cl_2 = Cl_2POCl + EtCl$); but Geuther a. Michaelis (*J. Z.* 6, 242) pointed out that this formation of $POCl_3$ may be interpreted also in favour of the constitution Cl_3PO by supposing that Cl first replaces OEt, forming PCl_3, and that the PCl_3 and EtOCl then react;

(1) $Cl_2POEt + Cl_2 = Cl_3P + EtOCl$,
(2) $Cl_3P + EtOCl = Cl_3PO + EtCl$. The experiments of Reinitzer a. Goldschmidt (*B.* 13, 845) on the action of metals, on $POCl_3$ show that in most cases O is withdrawn, leaving PCl_3; and that in a few cases the 3 Cl atoms are withdrawn with formation of P_2O_5. These results do not indicate any differences between the functions of the Cl atoms, and hence they tend to favour the formula Cl_3PO. Thorpe (*C. J.* 37, 387) arrived at the formula Cl_2POCl from consideration of the specific volumes of $POCl_3$ and PCl_3. Masson a. Ramsay (*C. J.* 39, 50), also from considering the specific volumes of P and P compounds, deduced the formula $OPCl_3$. Although but one $POCl_3$ has been obtained, the isomeric compounds $(C_6H_5)_2POC_6H_5$ and $(C_6H_5)_3PO$ have been isolated (La Coste, *B.* 18, 2118).

Pyrophosphoryl chloride $P_2O_3Cl_4$ (*Phosphorus trioxytetrachloride*). Mol. w. not known. Boils 210°-215°, with partial decomposition. S.G. 1·58 at 7°.

Preparation.—1. 100 g. PCl_3 are placed in a cylinder surrounded by ice and salt, and the vapour from 20 g. liquid NO_2 is passed into the cylinder by a tube which reaches just to the surface of the PCl_3. The action proceeds at once; the products are P_2O_5, $POCl_3$, $P_2O_3Cl_4$, and NOCl. When all the NO_2 has been distilled into the PCl_3, the cylinder is placed in warm water to remove NOCl, and its contents are then fractionated; PCl_3 distils over first, then a considerable quantity of $POCl_3$ between 105° and 110°, and then $P_2O_3Cl_4$ from 200° upwards. It is best to prepare a considerable quantity of the impure product before fractionating; 350 g. PCl_3 yielded 40 g. $P_2O_3Cl_4$ (Geuther a. Michaelis, *B.* 4, 766).—2. The vapour obtained by heating 80 g. starch with 180 g. HNO_3Aq is led into 100 g. PCl_3; the product is fractionated, and that boiling under 100° is again treated as before; finally, the whole is fractionated. About 20 g. $P_2O_3Cl_4$ are obtained from 200 g. PCl_3 (G. a. M., *l.c.*).

Properties.—A colourless liquid, which fumes in the air; the vapour attacks cork. Has not been solidified by cooling. Boils, with partial decomposition into P_2O_5 and $POCl_3$, at 210°-214°.

Reactions.—1. *Heat* produces partial decomposition into $POCl_3$ and P_2O_5.—2. Decomposed by *water* to H_3PO_4Aq and HClAq.—3. *Alcohol* produces $PO.OEt.Cl_2$, $PO.OEt.(OH)_2$, and HCl. 4. *Phosphorus pentachloride* produces $POCl_3$. 5. *Phosphorus pentabromide* forms $POBr_3$ and $POCl_2Br$ (G. a. M., *l.c.*).

Metaphosphoryl chloride PO_2Cl. Gustavson (*B.* 4, 853) said that a compound of this composition is formed by heating P_2O_5 with $POCl_3$; but Michaelis (*G. O.* 2, 396) says that the substance is not a true compound, and this is confirmed by Huntly (*C. J.* 59, 242).

Phosphorus, oxychlorobromides of, *v.* Phosphorus, oxybromochlorides of, p. 142.

Phosphorus, oxyfluoride of, POF_3 (*Phosphoryl fluoride*). Mol. w. 103·92. V.D. 52 (Thorpe, *C. J.* 55, 759; Moissan, *Bl.* [3] 4, 260). A gas which fumes in air and is rapidly absorbed by water. Formed by the reaction of P_2O_5 with fluorides (Schulze, *J. pr.* [2] 21, 438); also by exploding a mixture of 2 vols. PF_3 and 1 vol. O by passing electric sparks (Moissan, *C. R.* 102, 1245); by gently heating an intimate mixture of 2 pts. finely-powdered cryolite with 3 pts. P_2O_5 in a brass tube, and collecting over Hg as soon as the gas which comes off is wholly absorbed by NaOHAq (Thorpe, *l.c.*). Moissan (*l.c.*) prepares POF_3 by heating ZnF_2 with $POCl_3$ in a brass tube, fitted with a leaden delivery tube; he allows the gas to pass through a brass tube cooled to −20°, and then over ZnF_2 to remove traces of $POCl_3$.

POF_3 liquefies at 16° under a pressure of 15 atmos., or at the ordinary pressure by cooling to −50° (M., *C. R.* 102, 1245). When compressed under 50 atmos. and the pressure then suddenly released, it solidifies to a snow-like mass. When quite dry it is without action on glass or Hg; heated in a glass tube SiF_4 and an alkaline phosphate are formed.

Phosphorus, oxyiodide of, $P_3I_6O_8$. Burton (*Am.* 3, 280) obtained a red crystalline compound, to which he gave this composition, as a by-product in preparing C_2H_5I. M.P. c. 140°; sublimable, with partial decomposition; e. sol. water, alcohol, and ether.

Phosphorus, oxynitride of, PON (*Phosphoryl nitride. Phosphoryl nitrile.* Formerly called *Phosphomonamide*). Mol. w. uncertain. A white powder, which melts at red heat to black glass-like mass. Obtained by heating $PO(NH_2)_3$ or $PONHNH_2$, the former of which is formed by the reaction of $POCl_3$ with NH_3, and the latter by the reaction of PCl_5 and NH_3 (Schiff, *A.* 101, 300; *cf.* Phosphamides, p. 105). Gives K_3PO_4 and NH_3 by action of molten KOH (*v.* also Gladstone, *C. J.* [2] 7, 18).

Phosphorus, selenides of. P and Se combine directly to form four compounds: P_4Se, P_2Se, P_2Se_3, and P_2Se_5. P_2Se, P_2Se_3, and P_2Se_5 combine with the selenides of the more positive metals to form compounds $R_2Se.P_2Se$, $(R_2Se)_2.P_2Se_3$, and $(R_2Se)_2.P_2Se_5$. The formulæ are not necessarily molecular.

Phosphorus subselenide P_4Se (*Phosphorus hemiselenide*). Prepared by melting together Se and ordinary P in the ratio Se : 4P(1:1·57) in an atmosphere free from O, and separating from amorphous P by distillation in absence of O. A dark yellow, oily, fetid-smelling liquid, which solidifies at −12°; e. sol. in CS_2, insol. alcohol and ether; takes fire in air; decomposed by water containing air, with formation of H_3PO_4Aq and Se compounds; not acted on by cold alkali solutions, but with boiling alkali solutions gives alkali phosphate and selenite, metallic selenide and P hydride; in solutions of metallic salts becomes covered with a crust of metallic phosphide and selenide (Hahn, *J. pr.* 93, 430).

Diphosphorus selenide P_2Se. (*Phosphorus protoselenide* or *monoselenide*). Prepared by melting together, in absence of O, P, and Se in ratio 2P : Se(1:1·28). A red solid; unchanged in dry air, in moist air gives off H_2Se; insoluble alcohol and ether; P is withdrawn by CS_2; boiling alkali solutions produce H_2Se and a red substance containing Se and P. By heating, in absence of O, with equivalent weights of metallic selenides, compounds $R^I{}_2Se.P_2Se$ and $R^{II}Se.P_2Se$ are formed; R = Ba, Cu, Fe, Mn, K, Ag, Na. The alkali compounds are decomposed by water; the compounds containing heavy metals decompose only at high temperatures, but they generally take fire when rubbed in a mortar; they are slowly decomposed by hot alkali solutions (Hahn, *l.c.*). From their empirical composition, R^IPSe, these compounds might be called *seleno-meta-hypophosphites.*

PHOSPHOROUS SELENIDE P_2Se_3. (*Phosphorus sesquiselenide* or *triselenide*). Prepared by heating together P and Se in ratio 2P:3Se(1:3·82) in absence of O. A dark ruby-red solid; sublimes to yellow vapours when heated out of O; burns when ignited in air. Oxidised slowly in moist air; evolves H_2Se when boiled with water. Insoluble alcohol, ether, and CS_2; easily soluble in potash, less soluble in alkali carbonate solutions. Forms compounds with metallic selenides $(R^I{}_2Se)_2.P_2Se_3$, and $2R^{II}Se.P_2Se_3$ (Hahn, *l.c.*); R = Ba, Cu, Pb, Mn, K, Ag, Na. From their empirical composition, $R^I{}_4P_2Se_5$, these compounds might be called *selenopyrophosphites.*

PHOSPHORIC SELENIDE P_2Se_5 (*Phosphorus pentaselenide*). Prepared by heating together amorphous P and Se in ratio 2P:5Se (1:6·37) in a stream of CO_2. A dark-red, nearly black, glass-like solid; insoluble in CS_2; crystallises from CCl_4 in black needles. In moist air, or water, decomposes slowly to H_2Se and H_3PO_4Aq; in conc. KOHAq quickly forms K_2Se and K_3PO_4Aq; alcohol forms H_2Se and $Et_3PO_2Se_2$ and also $Et_2HPO_2Se_2$. Very unstable compounds probably of the forms $(R^I{}_2Se)_2.P_2Se_5$ and $2R^{II}Se.P_2Se_5$ are obtained by heating P_2Se_5 with metallic selenides; R = Ba, Cu, Pb, Mn, K, Ag, Na. The empirical composition of these compounds would lead to the name *selenopyrophosphates* (Bogen, *A.* 124, 57; Rathke, *A.* 152, 200). Rathke (*l.c.*) supposed that the K salt of a selenophosphoric acid is formed by the reaction of P_2Se_5 with KOHAq.

Phosphorus, selenion acids of, salts of; *v.* DIPHOSPHORUS SELENIDE, PHOSPHOROUS SELENIDE, and PHOSPHORIC SELENIDE (*supra*).

Phosphorus, sulphides of. P and S combine, when heated together, with production of much heat and light; the action is often violently explosive. Four definite compounds seem to exist; the simplest formulæ are P_4S_3, P_2S_3, PS_2, and P_2S_5.

Two compounds containing less S than P_4S_3, viz. P_2S and P_4S, are often described, and substances said to be compounds of P and S in the ratio P : 3S and P : 6S have been mentioned by Dupré and Berzelius.

The substance to which the formula P_4S was given was obtained by heating P and S in the proper proportions (Berzelius, *A.* 46, 129, 255), or by digesting P with an alcoholic solution of K_2S_5 (Böttger, *J. pr.* 12, 357), or according to Wicke (*A.* 86, 115) by contact of P and S at ordinary temperatures; it was described as a colourless, oily liquid. A solid red form of P_4S was said to be formed by heating liquid P_2S with Na_2CO_3 (Berzelius, *l.c.*). The formula P_2S was given to a substance of which two forms were described: a yellow liquid obtained by carefully heating together P and S in the proper ratio, and a dark-red powder obtained by heating the liquid form with dry MnS in H (Berzelius, *l.c.*). Various double compounds of P_2S with metallic sulphides, $R^I{}_2S.P_2S$ and $R^{II}S.P_2S$ (R = Cu, Fe, Mn, Hg, Ag) were described by Berzelius. The composition of these bodies would lead to their being called *thiometahypophosphites.* Isambert (*C. R.* 96, 1771) has shown that when a solution of P in a large excess of S is distilled *in vacuo* the whole of the P passes off and leaves S. Schulze (*J. pr.* [2] 22, 113) found that P separated at 8° from a solution of S in P in the ratio P_4S, and that S separated when the elements were present in the ratio P_2S. Schulze also found that a stream of CO_2 removed P from both solutions at 150°; that heating to this temperature generally produced explosion; that the so-called liquid P_2S was soluble in CS_2, and that most of the S was removed by shaking this solution with alcohol, ether, or $CHCl_3$. Further, Schulze (*B.* 16, 2066) observed that solutions of S in P, in the ratio P_4S and P_2S, did not solidify homogeneously, but that P separated from the first, and S from the second, solution. From these facts Isambert and Schulze concluded that the so-called P_4S and P_2S are merely solutions of S in P. Lemoine (*C. R.* 96, 1630) maintained that these substances were true compounds. According to Mai (*A.* 265, 192), when 67 parts P and 96 parts S are melted together, and the product is distilled at 10–11 mm. pressure, a distillate is obtained which slowly solidifies, and digestion of this solid with CS_2 under pressure gives a solution from which crystals of P_4S_7 separate, and the mother-liquor deposits what seems to be a mixture of P_2S_3 and P_4S_5. The melting-points of mixtures of P and S are much below those of either constituent (Pelletier, *A. Ch.* [2] 4, 1; Faraday, *A. Ch.* [2] 7, 71; Dupré, *A. Ch.* [2] 73, 435). The experiments of Faraday (*l.c.*) and Ramme (*B.* 12, 940, 1350) show that the crystals obtained by dissolving S in liquid P sulphides—to which Berzelius gave the composition PS_{12}, and Dupré the composition PS_6—are merely S with more or less adhering P.

TETRAPHOSPHORUS TRISULPHIDE P_4S_3 (*Sesquisulphide of phosphorus. Hypophosphorous sulphide*). Mol. w. 219·8. Melts at 166° (Ramme *B.* 12, 1350). Boils at 380° (Isambert, *C. R.* 96, 1499). S.G. 2·0 at 11°. V.D. 114·3 (Isambert, *l.c.*; Ramme, *l.c.*). H.F. $[P^4,S^3] = 86,800$ (I., *l.c.*).

Formation.—1. By heating together P and S in the ratio 4P:3S.—2. By heating P_4S_6 with ordinary P to 320° (Ramme, *l.c.*).

Preparation.—A mixture of 1 part S with 1·3 parts amorphous P is placed in a flask with a long wide neck connected with a wide tube dipping beneath the surface of Hg; the mixture is heated towards 260°, when the reaction begins, and proceeds with production of much heat; the product is dissolved in CS_2 and crystallised (Lemoine, *Bl.* [2] 1, 407). Ramme (*B.* 12, 1350) heats the red P and S together in a sealed tube at 260° for eight hours. If ordinary P is used, combination occurs at 130°, with violent explosion. The explosion may be prevented by melting the S and P in the water-bath, and adding twice as much sand from which air has been removed by CO_2 (Isambert, *C. R.* 96, 1499). Ramme (*B.* 12, 1351) obtained P_4S_3 by heating P_4S_6 with ordinary P in a sealed tube, filled with CO_2, to 320°.

Properties.—A yellow crystalline solid, which melts at 167° to a slightly coloured liquid. Boils 230°-240° at 11 mm. pressure, with partial decomposition to red P (Mai, *A.* 265, 192). Crystallises from CS_2, PCl_3, or $PSCl_3$ in rhombic prisms (Lemoine, *Bl.* [2] 1, 407); sublimes under 800°, probably in regular crystals (Isambert, *C. R.* 96, 1499). Very soluble CS_2, $PSCl_3$, and PCl_3; dissolved and decomposed by alcohol (Lemoine, *l.c.*). Burns at c. 100° to P_2O_5 and SO_2; scarcely changed in ordinary air.

Reactions.—1. Burns when *heated in air* to c. 100°, forming P_2O_5 and SO_2.—2. Not acted on by cold *water*; hot water slowly produces H_2S and H_3PO_3Aq.—3. Dissolves in *potash solution*, forming K phosphite and sulphide, and evolving H and P hydride (Lemoine, *l.c.*).—4. *Hydrated lead oxide* reacts at 200° with separation of PbS (L., *l.c.*).—5. Soluble in *potassium sulphide* solution, probably with formation of a double compound (L., *l.c.*).—6. *Chlorine*, when moist, slowly produces H_2SO_4 and H_3PO_4 (L., *l.c.*; I., *l.c.*).—7. Not acted on by cold *sulphuric* or *hydrochloric acid*; *nitric acid* and *aqua regia* oxidise P_4S_3 slowly and regularly on warming.

Phosphorous sulphide P_4S_6 (*Trisulphide of phosphorus. Tetraphosphorus hexasulphide. Thiophosphorous anhydride*). Mol. w. 315·72. Melts at c. 200°, and boils at c. 490°. V.D. 147·5, to 173·6 at lower temperatures (Isambert, *C. R.* 102, 1386).

Formation.—1. By heating red P and S in the ratio 2P:3S in CO_2. Combination occurs without explosion, but so much heat is produced that a part of the product sublimes rapidly (Kekulé, *A.* 90, 310; Michaelis, *A.* 164, 22).—2. By the reaction of PCl_3 with H_2S (Serullas, P. 17, 101). Ramme (*B.* 12, 940) failed to obtain P_4S_6 by heating a solution of P and S in CS_2 in a sealed tube.

Preparation.—A mixture is made of 1 part red P with 1·55 parts S; a small portion of this mixture is heated in a long-necked flask in a stream of CO_2 until combination occurs; the flame is removed, and the rest of the mixture is introduced into the flask in small portions at a time; the heat produced by the combination of one quantity suffices to cause combination of the next quantity. The P_4S_6 is sublimed into the neck of the flask; or it may be dissolved in CS_2 and crystallised (Michaelis, *A.* 164, 22).

Properties.—A greyish-yellow, crystalline, solid (Kekulé, *A.* 90, 310; Isambert, *C. R.* 102, 1386). Tasteless, inodorous; does not fume in air; melts readily (c. 200°), and sublimes more easily than S. Soluble in CS_2. The V.D. shows that the molecular formula is P_4S_6, corresponding with the oxide P_4O_6. P_4S_6 acts as a thio-anhydride, forming compounds with the sulphides of several metals (*v. Reactions*, No. 7). As P_4S_6 is acted on by moist air, it must be kept in sealed tubes.

Reactions.—1. Decomposes rapidly in *moist air* (? to H_2S and H_3PO_3).—2. Decomposed by *water* to H_2S and H_3PO_3Aq.—3. Burns when *heated in air.*—4. Dissolves in *potash, soda, or ammonia solution*, and is reppd. in yellow flocks by addition of acid.—5. Decomposes *carbon compounds containing* OH, forming corresponding SH compounds and H_3PO_3.—6. With *iodine* in CS_2 forms PI_2 (Isambert, *C. R.* 96, 1771).—7. According to Berzelius, P_2S_3 combines with many metallic sulphides forming compounds $2R^I_2S.P_2S_3$ and $2R^{II}S.P_2S_3$ the composition of which would lead to their being calle *thiopyrophosphites*; R = Cu, Fe, Hg, Ag.—8. B dissolving in *caustic soda* solution cooled to 0 Lemoine (*C. R.* 93, 489; 98, 45) obtained th compound $P_2OS_2.2Na_2O.5H_2O$ and the compoun $P_2OS_2.3Na_2O.4H_2O$; and by using *ammoniu* *sulphide* he obtained $P_2OS_2.2(NH_4)_2O.3H_2O$ an $P_2O_2S.2(NH_4)_2O.6H_2O$. These substances evolve H_2S by the action of HClAq; heated to 200°-240° they gave off H_2S, but retained S; the may perhaps be called *thio-oxypyrophosphites.*

Triphosphorus hexasulphide P_3S_6 (*Phosphorus disulphide* [PS_2]. *Phosphorus tetrasulphide* [P_2S_4]). ? Mol. w. 284·8. Melts at 296°-298° (Ramme, *B.* 12, 940); at 248°–249° (Seiler *Dissertation*, Göttingen, 1876). Boils at 335°-340° at pressure of 10–11 mm. (Mai, *A.* 265, 192). V.D. Ramme (*B.* 12, 1350) says that V. D. agrees with formula P_3S_6, but no numbers are given.

Formation.—1. By heating a solution of P and S in CS_2 in sealed tubes to 210°; according to Ramme (*B.* 12, 940), P_3S_6 is produced with P and S in the following ratios:—P:S, P:2S, 2P:S, 3P:S, 4P:S, 6P:S (*v.* also Dervin, *Bl.* [2] 41, 433).—2. By heating together P and S in the ratio P:2S (Seiler, *l.c.*).

Preparation.—P and S are dissolved in CS_2 in the ratio P:2S, the solution is heated in a sealed tube to 210° for 8–10 hours, after cooling the liquid is poured off, and the crystals are recrystallised repeatedly from CS_2 in a sealed tube (Ramme, *l.c.*).

Properties and Reactions.—Long, clear yellow, needle-shaped crystals. Ramme (*l.c.*) says that V.D. corresponds with formula P_3S_6 but he gives no data; the corresponding oxide is generally written P_2O_4, but its molecular weight has not yet been determined. Heated with water in a sealed tube to 150° for some hours, P_3S_6 gave H_2S, H_3PO_3Aq, and H_3PO_4Aq, and an orange-yellow solid insoluble in CS_2 and not melting at 310° (Ramme, *B.* 12, 1350).

Phosphoric sulphide P_2S_5 (*Phosphorus pentasulphide* or *persulphide. Thiophosphoric anhydride*). Mol. w. 221·8. Melts at 274°–276° (V. a. C. Meyer, *B.* 12, 610). Boils at 518°, pressure = 730 mm. (Goldschmidt, *B.* 15, 303); at 520° (Isambert, *C. R.* 102, 1386); at 530° (Hittorf, *P.* 126, 196); at 332°–340°, pressure being 11 mm. (Mai, *A.* 265, 192). V.D. 110·7, at 530° in N (V. a. C. Meyer, *B.* 12, 610).

Formation.—1. By heating a solution of ordinary P and S, in the proper ratio, in CS_2 to 210° for 8–10 hours, and crystallising from CS_2 (Ramme, *B.* 12, 940).—2. By melting together red P and S, in ratio 2P:5S, in CO_2 (Kekulé, *A.* 90, 310); with ordinary P violent explosion occurs.

Preparation.—A mixture of 40 parts S and 18·5 parts red P is melted together, the mass is powdered, placed in a retort filled with CO_2, and distilled to c. ⅓ to ½ (to remove P, S, and more volatile P sulphides); the residue is again powdered and distilled in CO_2; the distillate is pure P_2S_5 (V. a. C. M., *l.c.*).

Properties.—Large, clear, pale-yellow crystals. Vapourises in N or CO_2, without change, to a yellowish gas. Burns when heated in air.

Soluble in CS_2; P_2S_5 seems to react as a thio-anhydride (*v. Reactions*, No. 7).

Reactions.—1. Decomposes in *moist air* or by *water*, to H_2S and H_3PO_4; burns when *heated in air* to P_2O_5 and SO_2.—2. With *phosphorus pentachloride* forms $PSCl_3$ (Weber, *J.* 1859. 80). 3. With *carbon tetrachloride* at 200° produces CS_2 and $PSCl_3$ (Rathke, *Z.* 1870. 57).—4. With *ferric chloride* gives FeS_2 and $PSCl_3$ (Glatzel, *B.* 23, 37).—5. With *sulphonyl chloride*, $PSCl_3$, SO_2, and S are formed (Prinz, *J. Z.* 13, *Supplbd.* 1, 90).—6. With many *carbon compounds containing* O and also with many *inorganic oxides*, P_2S_5 form S compounds, exchanging S for O (Kekulé, *A.* 90, 310; Carius, *A.* 106, 331; 112, 180; *v.* also Prinz, *l.c.*).—7. According to Berzelius (*A.* 46, 129, 255), P_2S_5 combines directly with several metallic sulphides, forming compounds $2R^I_2S.P_2S_5$ and $2R^{II}S.P_2S_5$ (R = Cu, Fe, Mn, Hg, Zn): these compounds may be called *thiopyrophosphates.*

THIO-OXYORTHOPHOSPHATES. Salts of the hypothetical acids H_3PSO_3 (*monothio-oxyorthophosphoric acid*) and $H_3PS_2O_2$ (*dithio-oxyorthophosphoric acid*) have been obtained by the action of alkali solution on P_2S_5 or on $PSCl_3$. Salts of *trithio-oxyphosphoric acid* (H_3PS_3O) have not been isolated.

Monothio-oxyphosphates. The Na salt, $Na_3PSO_3.12H_2O$ was obtained by Wurtz by warming $PSCl_3$ with fairly conc. NaOHAq (*A. Ch.* [3] 20, 472), and by Thorpe a. Rodger by the action of NaOHAq on PSF_3 (*C. J.* 55, 318). Kubierschi (*J. pr.* [2] 31, 93) obtained the salt by adding powdered P_2S_5 to NaOHAq, in ratio P_2S_5:6NaOH, cooling, adding absolute alcohol—which ppd. a mixture of Na_3PSO_3 and $Na_3PS_2O_2$ (leaving Na polysulphides in solution)—dissolving the pp. in water, warming to 90° till H_2S ceased to come off, evaporating, and crystallising. Thin six-sided prisms, melting at 60°. The Mg salt (with $20H_2O$), and the Mg-NH_4 salt (with $9H_2O$) were also obtained.

Dithio-oxyphosphates. The Na salt, $Na_3PS_2O_2.11H_2O$ was obtained (K., *l.c.*) by dissolving in water the pp. obtained as above by alcohol, warming to 50°-55°, ppg. by alcohol, and crystallising from water at 40°. Colourless, lustrous, needles, melting at 45°-46°. The NH_4 salt (with $2H_2O$), Ba salt (with $8H_2O$), and Mg-NH_4 salt (with $6H_2O$) were also obtained in crystalline form.

For reactions of these thio-oxyorthophosphates *v.* Kubierschi, *l.c.* (*cf.* Michaelis, *B.* 5, 5).

Phosphorus, sulphobromides of. Two compounds, corresponding with the two oxychlorides, have been prepared.

THIOPHOSPHORYL BROMIDE $PSBr_3$ (*Sulphophosphoryl bromide. Phosphorus sulphobromide*). Formula probably molecular, from analogy of $POCl_3$.

Formation.—1. By reaction of H_2S with PBr_5 (Gladstone, *P. M.* 35, 345; Baudrimont, *A. Ch.* [4] 2, 58).—2. By distilling PBr_3 with S, or Br with P_2S_3.—3. By the action of Br on a solution of P and S in CS_2.

Preparation.—Equal parts of P and S are dissolved in CS_2, the solution is well cooled, and 8 parts Br are allowed to drop in slowly from a funnel with a stopcock; the CS_2 is removed by warming in a water-bath, and the liquid is then distilled quickly over a large flame. Part of the $PSBr_3$ solidifies in the neck of the retort, and part passes over and remains liquid in the receiver; the contents of the receiver are shaken with fresh quantities of water until the oily liquid solidifies to a yellow crystalline mass which is $PSBr_3.H_2O$; this hydrate is dissolved in CS_2, water is removed by contact with $CaCl_2$, CS_2 is distilled off in a stream of CO_2, and $PSBr_3$ remains as a yellow oil, which solidifies on touching it with a glass rod. The solid may be recrystallised from PBr_3 (Michaelis, *A.* 164, 36).

Properties.—Yellow octahedral crystals, with an aromatic but unpleasant odour; vapour attacks the eyes. Melts at 38°, when molten remains for a long time without solidifying unless touched by a solid (Michaelis, *B.* 4, 777). Easily soluble in ether, CS_2, PBr_3, or PCl_3. Cannot be distilled without decomposition.

Reactions.—1. Decomposed by *heat* to S and a yellow liquid, $PSBr_3.PBr_3$, which is resolved by repeated distillation into S and PBr_3, and by repeated washing with water yields $PSBr_3.H_2O$ (Michaelis, *A.* 164, 36).—2. Decomposed by *water*, slowly when cold, rather more rapidly when boiling, forming H_2S, S, H_3PO_3Aq and H_3PO_4Aq (*v.* Michaelis, *B.* 5, 4).—3. With *alcohol* forms $PS(OEt)_3$.—4. Decomposed by *ammonia solution*, slowly when cold, more rapidly when hot, giving NH_4 phosphite and phosphate, H_2S, S, and NH_4 sulphide (M., *l.c.*). 5. Reacts with *phosphorus pentachloride* to form $PSCl_3$ and PBr_5 (M., *l.c.*).

Combinations.—1. With *water* to form $PSBr_3.H_2O$ (*v. Preparation*). A yellow crystalline solid; melts at 35°, being resolved into H_2O and $PSBr_3$; S.G. 2·7937 at 18°; gradually decomposes in air, giving off HBr (Michaelis, *A.* 164, 36).—2. With *phosphorus bromide* to form $PSBr_3.PBr_3$; obtained by heating $PSBr_3$ (*v. Reactions*, No. 1).

PYROPHOSPHORYL BROMIDE $P_2S_3Br_4$ (*Phosphorus trisulphotetrabromide*). A light-yellow oil, with aromatic and pungent odour; S.G. 2·2621 at 17°; fumes in air, with separation of S. Decomposed by *distillation* into S, P_2S_5, and $PSBr_3.PBr_3$; decomposed by *water*, giving S, $PSBr_3$, H_2S, P, and a substance probably $P_2S_3(OH)_4$; *alkalis* act similarly to, but more violently than, water, but neither S nor $PSBr_3$ is formed; with *absolute alcohol* yields $P_2S_3(OEt)_3Br$, $P_2S_3(OEt)_4$, $P_2S_3(OEt)_2(SEt)_2$; *bromine* reacts, when heated, forming PBr_5 and $PSBr_3$ (Michaelis, *A.* 164, 22). Prepared by moistening 100 g. finely powdered P_2S_3 with CS_2, and adding 200 g. Br diluted with an equal volume of CS_2, shaking thoroughly, distilling off CS_2 in water-bath not above 80°, removing last traces of CS_2 in stream of CO_2, dissolving residue in six times its volume of dry ether, and removing ether by a stream of CO_2 (M., *l.c.*).

Phosphorus, sulphobromochloride of, $PSBrCl_2$ (*Thiophosphoryl bromochloride*). Formula probably molecular, from analogy of $POBrCl_2$ (Michaelis, *B.* 5, 6). A slightly yellow liquid, with aromatic odour; boils c. 150°, but boiling-point soon rises and S separates. Decomposed slowly by *water*, more completely when heated in a sealed tube to 150° for some hours, giving S, H_2S, HClAq, HBrAq, H_3PO_3Aq, and H_3PO_4Aq. Prepared by adding 80 parts Br drop by drop to 168 parts $PCl_2.SEt$ [obtained by action of EtSH on PCl_3; for details *v.* Michaelis, *l.c.*]; much heat is produced; the liquid is distilled, the distillate from 150°–180° is shaken with water so long as any action takes place; water is removed by a separating funnel; the liquid is dried by $CaCl_2$, and HCl and HBr are removed by warming gently (M., *l.c.*).

Phosphorus, sulphochlorides of. But one compound, $PSCl_3$, is known with certainty. It is doubtful whether the substance obtained by Gladstone (*C. J.* 3, 5) by the reaction of S with PCl_3 is a definite compound PS_2Cl_5, or a double compound $PSCl_3.SCl_2$.

THIOPHOSPHORYL CHLORIDE $PSCl_3$ (*Phosphorus sulphochloride*). Mol. w. 169·05. Boils at 125·12° (Thorpe, *C. J.* 37, 341). S.G. $^{0^\circ}_{4^\circ}$ 1·6682 (T., *l.c.*). V.D. 85 at 160°–300° (Cahours, *A. Ch.* [3] 20, 369; Chevrier, *C. R.* 68, 1174). For thermal expansion *v.* Thorpe (*l.c.*). S.V. 116·1.

Formation.—1. By the reaction of H_2S with PCl_5 (Serullas, *A. Ch.* [2] 42, 25).—2. By heating S with PCl_3 to 130° (Henry, *B.* 2, 638).—3. By heating P with S_2Cl_2 (Wöhler a. Hiller, *A.* 93, 274).—4. By heating together P_2S_5 and PCl_5 (Weber a. Thorpe, *Z.* 1871. 467).—5. By the reaction of PCl_3 with SO_2, SO_2Cl_2, or S_2Cl_2; and by the reaction of PCl_5 with CS_2, or with Sb_2S_5 (Michaelis; Cairns, *A.* 112, 190; 119, 291; Rathke, *Z.* 1870. 57; Baudrimont, *J. pr.* 87, 301).

Preparation.—An intimate mixture of P_2S_5 and PCl_5, in the ratio $P_2S_5 : 3PCl_5 (= 1:2·82)$, is heated in a sealed tube to c. 120°; after a short time the liquid which has formed is distilled. Should the product have a yellowish colour, it is shaken with a little water, dried by $CaCl_2$, and distilled. The equation $P_2S_5 + 3PCl_5 = 5PSCl_3$ is realised (Thorpe, *C. J.* 37, 341).

Properties.—A colourless, highly refractive liquid; with an aromatic, somewhat pungent, and very peculiar odour, which becomes very marked on warming. Slowly decomposed by water.

Reactions.—1. Very slowly acted on by *water*, with formation of H_3PO_4Aq, HClAq, and H_2S. When distilled in steam the greater part of the $PSCl_3$ passes over unchanged.—2. Heated with *alcohol* under pressure, $PS(OEt)_3$ is formed.—3. Passed through a hot tube, with excess of *hydrogen sulphide*, P_2S_3 and HCl are formed (Baudrimont, *J. pr.* 87, 301).—4. Decomposed by *chlorine* with formation of S_2Cl_2 and PCl_5.—5. *Silver nitrate* reacts rapidly, producing Ag_3PO_4, AgCl, SO_2, NOCl, and NO_2 (the SO_2 and NO_2 then reacting to form $S_2O_5(NO_2)_2$; Thorpe a. Dyson, *C. J.* 41, 297).—6. *Alkali solutions* form salts of H_3PSO_3 and $H_3PS_2O_2$ (*v.* THIOOXYORTHOPHOSPHATES, p. 147).—7. The prolonged action of *ammonia*—continued until 60 p.c. of the $PSCl_3$ has reacted with the NH_3—produces ***thiophosphamide*** $PS(NH_2)_3(?)$; this compound remains as an amorphous, yellow-white solid on washing the product of the action of NH_3 on $PSCl_3$; S.G. 1·7 at 13°; decomposed at 200°, gives (?)$PS(ONH_4)_3$ with hot water (Chevrier, *C. R.* 66, 748; Schiff, *A.* 101, 292). According to Gladstone a. Holmes (*C. J.* 18, 5), ***thiophosphamic acid*** $PS(NH_2)(OH)_2$ and ***thiophosphodiamic acid*** $PS(NH_2)_2OH$, are produced by the action of ammonia on $PSCl_3$; the former by using fairly dilute NH_3Aq, and the latter by using NH_3 gas—which probably forms $P(NH_2)_2ClS$—and then washing with water. The work of Chevrier (*l.c.*) and Schiff (*l.c.*) makes the isolation of these acids doubtful.

Phosphorus, sulphochlorobromide of; *v.* PHOSPHORUS SULPHOBROMOCHLORIDE, p. 147.

Phosphorus, sulphocyanide of, $P(SCN)_3$ (*Phosphorus thiocyanate. Phosphorus rhodanide*). Mol. w. not determined; formula probably molecular. Prepared by mixing 5 parts $Pb(SCN)_2$ with an equal weight of dry sand, gradually adding 1 part PCl_3, digesting for some time on a water-bath, and then distilling very carefully from a hard glass tube. A liquid which does not solidify at −20°, begins to boil 260°–270°, and decomposes at a higher temperature, giving off CS_2; vapour is spontaneously inflammable; S.G. 1·625 at 18°. Soluble in alcohol, ether, $CHCl_3$, CS_2, and C_6H_6. Slowly decomposed by cold water to H_3PO_3Aq and HSCNAq (Miguel, *A. Ch.* [5] 11, 349).

Phosphorus, sulphofluoride of, PSF_3 (*Thiophosphoryl fluoride*). This compound was prepared and fully described by Thorpe a. Rodgers in 1888 (preliminary notice in *C. J.* 53, 760; fuller account in *C. J.* 55, 306). Mol. w. 119·9. V.D. 59·6 at ordinary temperature.

Formation.—1. By heating a mixture of AsF_3 and $PSCl_3$, in ratio $AsF_3 : 4PSCl_3$, in a sealed tube at 150°.—2. By heating PbF_2 mixed with P_2S_5 to c. 120°–150°; or by using BiF_3 in place of PbF_2 and heating to a higher temperature. A mixture of red P, S, and a large excess of PbF_2 may also be used ($P_2S_5 + 3PbF_2 = 3PbS + 2PSF_3$). 3. By heating S with PF_3Cl_2 to 115° (Poulenc, *C. R.* 113, 75).

Preparation.—A quantity of P_2S_5 (freshly prepared from well-washed and perfectly dry amorphous P and roll S) is quickly mixed with c. $3\frac{1}{3}$ parts of pure freshly fused PbF_2, and the mixture is placed in a thin equal layer in a dry tube of lead or 'composition,' one end of which is fitted with a caoutchouc cork carrying a glass delivery tube dipping under dry Hg, and the other end is connected with an apparatus for supplying pure dry N. A rapid stream of N is passed through till the air is driven out, the tube being gently heated to get rid of traces of H_2S (produced by moisture on P_2S_5); the N is stopped, and the tube is heated from behind forwards by a small flame; reaction begins c. 170°; the temperature should be kept as low as possible, it must not exceed 250°. The gas is collected in a dry glass gas-holder containing a few small pieces of quicklime, the gas being allowed to pass into the holder as soon as a sample is wholly absorbed by dilute potash or ammonia. Before collecting the gas, small quantities of dry N should be passed into the gasholder and repeatedly exhausted by the Sprengel pump (this removes air from the pores of the lime), and when 2 or 3 c.c. of the $PSCl_3$ have passed into the holder the gas should be sucked out by the Sprengel, and this repeated twice or thrice (the traces of N are thus removed). After standing a few days over the lime, which removes PF_3 and any traces of SiF_4, the gas is pure PSF_3.

Properties.—A transparent, colourless gas; liquefied at 7·6 atmos. at 3·8°, 9·4 atmos. at 10°, 10·8 atmos. at 18·6°, and 13 atmos. at 20·3°. PSF_3 is spontaneously inflammable in air or O; it is decomposed easily by heat or electric sparks to S, P, and fluorides of P. Somewhat soluble in ether. Not easily dissolved by H_2O, or by solutions of alkalis. No action on Hg, H_2SO_4, CS_2, or C_6H_6. Neither gaseous nor liquid PSF_3 acts appreciably on glass at ordinary temperatures.

Reactions.—1. A small stream of PSF_3 issuing from a Pt jet into *air* at once takes fire; when mixed with a large volume of air, explosion occurs.—2. Oxidised rapidly and explosively by *oxygen*; probably with formation of PF_3 and SO_2, the PF_3 and O then producing P_2O_5 and also POF_3. The ignition-temperature of PSF_3 is very low, and the flame is a very cold one. (Full details are given by T. a. R., *l.c.*, pp. 312–317.)—3. Slowly decomposed by *water*, thus: $PSF_3 + 4H_2O + Aq = H_2S + H_3PO_4Aq + 3HFAq$. —4. Solution of *potash* or *soda* slowly reacts, forming Na_3PSO_3 and NaF.—4. With *ammonia gas* produces a white, deliquescent solid, probably a mixture of NH_4F and $P(NH_2)_2SF$. For action of water on this substance—perhaps resulting in formation of $PS(NH_2)_2OH$—*v.* T. a. R., *l.c.*, p. 319.—5. *Heated* in a *glass* tube, PSF_3 gives SiF_4, P, and S.—6. PSF_3 is decomposed by *electric sparks* passed from Pt terminals, with separation of S and P, and a gas which is probably PF_5.

Phosphorus, sulphoselenide of. All attempts to prepare this compound have led to negative results. Michaelis heated PCl_3 with Se; Baudrimont (*A. Ch.* [4] 2, 5) tried the reaction of PCl_5 with $SeCl_2$, PCl_5 with P_2Se, Sb_2Se_3, and PbSe, and the action of P on $SeCl_2$ and $SeCl_4$.

Phosphorus, sulphoxide of, $P_4O_6S_4$. Mol. w. 347·52. Melts at 102°, and boils at 295°. V.D. 171·3 at 350°–400°. Formed by heating small quantities P_4O_6 with S in an atmosphere of CO_2 or N at c. 160° (Thorpe a. Tutton, *C. J.* 59, 1022).

Preparation.—A strong glass tube is closed at one end, and filled with dry CO_2 or N; from 3 to 5 g. freshly-distilled P_4O_6 is placed in the bottom of the tube, and 1·74 g. S, best in small crystals, are added for every 3 g. P_4O_6 used (ratio P_4O_6:4S). The tube is sealed, and the lower half is immersed in a glycerin-bath, which is gradually heated. At c. 154°–165° the melted S is suddenly projected to the top of the tube, and in a few seconds the action is complete. The product is transferred to a similar tube, which is exhausted by a Sprengel pump, sealed, and warmed at its lower portion; sublimation begins at c. 90°, and proceeds best at 140°–150°, with formation of long feathery needles; part of the $P_4O_6S_4$ remains as a vitreous or crystalline mass.

Properties and Reactions.—A white solid, occurring in feathery aggregations or a vitreous mass, or as colourless, isolated, tetragonal prisms; melts 102°, and boils 295° (cor.). Very deliquescent, smelling in air of H_2S; quickly dissolved by water, forming H_2S and HPO_3Aq, which soon changes to H_3PO_4Aq. Easily sol. in 2 vols. CS_2, from which it crystallises unchanged. Also sol. benzene, but with decomposition.

Phosphorus, sulphur acids of, salts of; *v.* beginning of article Phosphorus sulphides (p. 145); Phosphorous sulphide, *Reactions* 7 and 8 (p. 146); Phosphoric sulphide, *Reaction* 7 (p. 147); and Thio-oxyorthophosphates (p. 147).

Phosphorus, telluride of. Oppenheim (*J.* 1857. 214) obtained a black amorphous solid, giving off fumes of P_2O_3 in air by heating P with powdered Te.

Phosphorus, thio-acids of, salts of; *v.* beginning of article Phosphorus sulphides (p. 145); Phosphorous sulphide, *Reactions* 7 and 8 (p. 146); Phosphoric sulphide, *Reaction* 7 (p. 147); and Thio-oxyorthophosphates (p. 147).

Phosphorus thio-amic acids of, and thio-amide of; *v.* Thiophosphoryl chloride, *Reaction* 7 (p. 148).

Phosphorus, thiobromides of; *v.* Phosphorus sulphobromides, p. 147.

Phosphorus, thiobromochloride of; *v.* Phosphorus sulphobromochloride, p. 147.

Phosphorus, thiochlorides of; *v.* Phosphorus sulphochlorides, p. 148.

Phosphorus, thiocyanide of; *v.* Phosphorus sulphocyanide, p. 148.

Phosphorus, thioselenide of; *v.* Phosphorus sulphoselenide, *ante.*

M. M. P. M.

PHOSPHORUS, OXYACIDS OF, AND THEIR SALTS. The three phosphoric acids, H_3PO_4, $H_4P_2O_7$, and HPO_3, are described under Phosphoric acids (p. 124); the salts of these acids are described under Phosphates (p. 108); the other oxyacids of P, and their salts, are described in this article.

Besides the phosphoric acids, three oxyacids of P, and some salts of a fourth acid, have been isolated; the acids in question are H_3PO_2, H_3PO_3, H_2PO_3 or $H_4P_2O_6$; and salts of $H_4P_2O_5$. No anhydride of H_3PO_2 is known; the hypothetical anhydride would be P_2O ($P_2O + 3H_2O = 2H_3PO_2$); P_2O_3 is the anhydride of the acid H_3PO_3 ($P_2O_3 + 3H_2O = 2H_3PO_3$), and also the hypothetical anhydride of $H_4P_2O_5$($P_2O_3 + 2H_2O = H_4P_2O_5$); P_2O_4 is the hypothetical anhydride of $H_4P_2O_6$($P_2O_4 + 2H_2O = H_4P_2O_6$), but this oxide gives H_3PO_3Aq and H_3PO_4Aq with water (*v.* Phosphorus tetroxide, p. 141). The oxyacids of P do not correspond in composition with those of N (*v. Table* in Nitrogen group of elements, vol. iii. p. 575).

HYPOPHOSPHOROUS ACID AND SALTS H_3PO_2; $M^IH_2PO_2$ and $M^{II}(H_2PO_2)_2$. Hypophosphites are formed by decomposing phosphide of Ba, Ca, or Sr by water (Dulong, *A. Ch.* [2] 2, 141); by heating P with potash, milk of lime, or BaOAq (H. Rose, *P.* 9, 225, 361; 12, 77, 288); by passing PH_3 into solution of alkalis or alkaline hydrates (Winckler, *P.* 111, 443); and by heating P with syrupy H_3PO_4Aq to 200° (Oppenheim, *Bl.* [2] 1, 163). The acid is monobasic; it may be regarded as derived from the hypothetical anhydride P_2O. There is no acid, nor are there salts, corresponding with hyponitrous acid HNO, but some salts are known of the form MPS; *v. Thiometahypophosphites*, at beginning of Phosphorus, sulphides of (p. 145). *Selenometahypophosphites* M^IPSe have also been isolated (*v.* Diphosphorus selenide, p. 144).

Hypophosphorus acid H_3PO_2. Melts at 17·4° (Thomsen, *B.* 7, 994; ? specimen pure). H.F. $[H^3,P,O^2] = 139,970$ (production of crystallised acid); 187,660 (production of acid in liquid state); $[H^3,P,O^2,Aq]$ = 139,800 (*Th.* 2, 225).

Preparation.—$Ba(H_2PO_2)_2.H_2O$ is prepared by warming water with BaO and P (in small pieces) in a basin till inflammable P hydride ceases to come off, filtering, removing excess of BaO by passing in CO_2, filtering again, and crystallising. 285 g. pure $Ba(H_2PO_2).H_2O$ are dissolved in c. 5 litres water, 98 g. H_2SO_4 (c. 101·5 g. ordinary conc. acid), diluted with 3 to 4 times its weight of water, are added; after shaking for some time the pp. of $BaSO_4$ is allowed to settle, and the clear liquid is syphoned off, and evaporated in a porcelain dish, by boiling, till it is c. $\frac{1}{10}$ of the original volume, when it is placed in a Pt dish; a thermometer is immersed in the liquid, evaporation is continued, the temperature being allowed to rise gradually to 110°; any solid which separates is filtered off while the liquid is hot, and the filtrate is evaporated, without being allowed to boil, at c. 110°. Thomsen (*B.* 7, 994) finally heats for 10 mins. to 130° or 138°, filters into a stoppered bottle, and cools below 0°; Geuther a. Ponndorff (*J. Z.* 10, *Supplbd.* 2, 45, 49) say that heating above 110° decomposes H_3PO_2, and that Thomsen's preparation therefore contained H_3PO_3.

Properties.—Large, white, crystalline tablets; melting at 17·4°; remains liquid considerably above m.p. (Thomsen, *l.c.*). Decomposed by heat to PH_3 and H_3PO_4. H_3PO_2Aq is a very energetic reducing agent. The acid is monobasic, forming salts $M^IH_2PO_2$ and $M^{II}(H_2PO_2)_2$.

Reactions.—1. Decomposed by *heat*, giving P hydride and H_3PO_4 (H. Rose, *l.c.*).—2. H_3PO_2Aq is readily changed to H_3PO_3Aq or H_3PO_4Aq by *oxidisers*; Cl, Br, HNO_3Aq, $KMnO_4Aq$, and several metallic oxides produce H_3PO_4Aq (Dulong, *l.c.*; Rose, *l.c.*; P. de St. Gilles, *A. Ch.* [3] 55, 374); PbO_2 forms $PbHPO_3$ (Wurtz, *C. R.* 18, 702); SO_2 forms H_3PO_3Aq and S (Geuther a. Ponndorff, *l.c.*). According to Engel (*C. R.* 110, 786) Pd charged with H oxidises H_3PO_2Aq to H_3PO_3Aq with evolution of H.—3. H_3PO_2Aq reduces *solutions of salts of gold, silver, and mercury*, ppg. the metals; from *copper sulphate solution*, Cu_2H_2 is ppd. at 55°-60° (Wurtz, *l.c.*; Rammelsberg, *l.c.*).—4. Reduced by *nascent hydrogen* to PH_3 (Dusart, *C. R.* 43, 1126; Blondlot, *C. R.* 52, 1197).—5. With *hydriodic acid* forms PH_4I (G. a. P., *l.c.*).—6. Heated with *conc. sulphuric acid*, H_3PO_4, SO_2, and S are produced (Wurtz, *l.c.*). 7. Heated with *phosphorus pentachloride*, $POCl_3$, PCl_3, and HCl are formed; *phosphorus trichloride* produces P, H_3PO_3, and HCl; with *phosphoryl chloride*, P, PCl_3, HPO_3, and HCl are the products (Geuther, *J. pr.* [2] 8, 359).

HYPOPHOSPHITES $M^IH_2PO_2$ and $M^{II}(H_2PO_2)_2$. These salts are formed in several reactions (*v.* beginning of this article); the greater number are prepared by reacting on the salt of Ba with the sulphates of other metals; the salts of Ba, Ca, and Sr are generally prepared by heating BaOAq, CaOAq, and SrOAq with P. The hypophosphites of Cd, Ca, Pb, and Tl crystallise without water; those of Ba, Li, Mn, Na, Sr, and U with one H_2O; those of Co, Mg, Ni, and Zn with $6H_2O$ (Rammelsberg, *C. J.* [2] 11, 12). They are decomposed by heat, evolving P hydride and H, and generally leaving pyro- and meta- phosphate, the Co and Ni salts leave metaphosphate and phosphide, and the U salt leaves pyro- and meta- phosphate and phosphide (R., *l.c.*). The hypophosphites are easily oxidised to phosphites and phosphates, hence they react as reducing agents. Heated in solution with alkalis they give phosphites, and then phosphates, and evolve H (Wurtz; H. Rose, *l.c.*). The chief memoirs on hypophosphites are by H. Rose (*P.* 9, 225, 361; 12, 77, 288); Wurtz (*A. Ch.* [3] 7, 193; 16, 196); and Rammelsberg (*C. J.* [2] 11, 1, 13).

Ammonium hypophosphite $NH_4H_2PO_2$. Hexagonal tablets; by decomposing the Ba salt by $(NH_4)_2SO_4Aq$; easily sol. absolute alcohol (Wurtz, Rose).

Barium hypophosphite $Ba(H_2PO_2)_2.H_2O$. Lustrous monoclinic needles (Rammelsberg; Topsöe, *W. A. B.* 69 [2] 19). By heating BaOAq with P till gas ceases to come off, filtering, removing BaO from the filtrate by CO_2, filtering, and crystallising. Loses H_2O at 100°. Soluble in $3\frac{1}{2}$ parts cold, and 3 parts boiling, water; insol. alcohol. Heated out of air leaves pyro- and meta- phosphate (Wurtz, Rose, Rammelsberg).

Calcium hypophosphite $Ca(H_2PO_2)_2$. Prepared like the Ba salt. Berlandt (*Ar. Ph.* [2] 122, 237) recommends 29 parts P, 47 parts CaO_2H_2, and 24 parts water. Bachmann and Martenson (*J.* 1864. 191) decompose Ca phosphide by boiling water. Thin, monoclinic tablets (Rammelsberg; Schabus, *J.* 1854. 325). Very bitter taste; unchanged in air; does not give off H_2O at 300°; heated to redness gives off H, PH_3, and H_2O, and leaves pyro- and meta- phosphate (Rammelsberg; Michaelis, *J.* 1872. 210). Sol. 6 parts cold water, not much more sol. hot water; insol. strong alcohol (Rose).

Cobalt hypophosphite $Co(H_2PO_2)_2.6H_2O$. Red octahedral crystals, isomorphous with Mg salt (Rose); by decomposing Ba salt by $CoSO_4Aq$, filtering, and evaporating *in vacuo* (Wurtz). Forms a *double salt* with $Ca(H_2PO_2)_2$ (Rose).

Copper hypophosphite $Cu(H_2PO_2)_2$. Obtained with difficulty from Ba salt and $CuSO_4Aq$; solution easily decomposes, giving Cu_2H_2 (Wurtz).

Lead hypophosphite $Pb(H_2PO_2)_2$. By adding PbO or $PbCO_3$ to H_3PO_2Aq (Rose, Wurtz).

Manganese hypophosphite $Mn(H_2PO_2)_2.H_2O$. Small, rose-red crystals; from Ba salt and $MnSO_4Aq$ (Wurtz, Rammelsberg); or by boiling Ca salt with Mn oxalate (Rose).

Potassium hypophosphite KH_2PO_2. Prepared by decomposing the Ba or Ca salt by K_2CO_3Aq, filtering, evaporating to dryness, treating the residue with alcohol, and crystallising the alcoholic solution *in vacuo*; or by dissolving P in boiling KOHAq, evaporating, and dissolving out from the residue by alcohol; also by decomposing the Ba salt by K_2SO_4Aq (Rose, Wurtz). A white, semi-crystalline mass. Easily sol. water and alcohol; very hygroscopic (Dulong, *A. Ch.* [2] 2, 141). Burns when heated in air; oxidised violently by evaporation with HNO_3Aq. Heated out of air evolves inflammable P hydride, and leaves pyro- and meta- phosphate (Rammelsberg).

Sodium hypophosphite $NaH_2PO_2.H_2O$. Prepared like the K salt. Small, rectangular tablets, easily sol. water and absolute alcohol. Evaporation of the solution is attended with explosions (Marquart, *Ar. Ph.* [2] 95, 284; Trommsdorff, *ibid.* 99, 388).

The salts $LiH_2PO_2.H_2O$, $Ni(H_2PO_2)_2.6H_2O$,

$Sr(H_2PO_2)_2$, and $Zn(H_2PO_2)_2$ are also described; and salts of Al, Be, Cd, Cr, and Fe have been obtained, but their compositions are somewhat doubtful.

PHOSPHOROUS ACID AND SALTS H_3PO_3; $M^IH_2PO_3$, $M^I_2HPO_3$, $M^{II}HPO_3$, $M^{III}_2(HPO_3)_3$. P_2O_3 is the anhydride of H_3PO_3; the acid is produced by dissolving the oxide in cold water, but the oxide is not obtained by removing H_2O from the acid. H_3PO_3 is dibasic; the salt Na_3PO_3, said to be formed by adding a large excess of NaOH to H_3PO_3 (Zimmermann), has been shown by Amat (*C. R.* 108, 403) not to exist. The acid is formed by oxidising P slowly in moist air; the salts are obtained by reactions between the acid and metallic hydroxides, or by double decomposition from the alkali salts. Neither the acid nor salts of the acid corresponding with nitrous acid, HNO_2, are known, nor have thio-salts of this form been isolated.

PHOSPHOROUS ACID H_3PO_3. Melts at 74° (Geuther a. Hurtzig, *A.* 111, 159); at 70·1° (Thomsen, *J. pr.* [2] 8, 359). H.F. $[H^3,P,O^3]$ $=227,700$ (crystallised acid); 224,630 (acid in liquid state); 227,570 (acid in aqueous solution) (*Th.* 2, 225). Heat of fusion $= -3070$; one gram-molecule of the liquid acid occupies 49·66 c.c. (*Th.* 2, 224).

Formation.—1. Along with H_3PO_2 and H_3PO_4, by the long-continued oxidation of P in moist air (*v.* J. Corne, *J. Ph.* [5] 6, 123).—2. By dissolving P in dilute HNO_3Aq and allowing to oxidise in air.—3. By the oxidation of H_3PO_2Aq by weak oxidisers.—4. By dissolving P_2O_3 in cold water (Thorpe a. Tutton, *C. J.* 57, 567).—5. By decomposing PCl_3 by H_2O, or by warming with $H_2C_2O_4$ (Hurtzig a. Geuther, *A.* 111, 159); or by leading Cl into warm water in presence of an excess of molten P (Droquet, *P.* 12, 628).

Preparation.—1. A small quantity of PCl_3 is shaken with cold water, the reaction is moderated by plunging the beaker into cold water; when the PCl_3 is all decomposed, a little more is added, and so on ($PCl_3 + 3H_2O + Aq$ $= 3HClAq + H_3PO_3Aq$). The solution is evaporated, the temperature being raised to 180° near the end of the process; the syrupy liquid thus obtained is placed over H_2SO_4, *in vacuo*, till it crystallises; addition of a crystal of H_3PO_3 causes rapid crystallisation (Thomsen, *B.* 7, 996). 2. A stream of dry air is passed through PCl_3 at 60°, and then into two flasks, each containing c. 100 g. water at 0°; after c. 4 hours the first flask is filled with crystals, which are drained under a pump, washed with small quantities of ice-cold water, and dried *in vacuo* (Grosheintz, *Bl.* [2] 27, 433).—3. A mixture of 1 part PCl_3 and 2 parts dry $H_2C_2O_4$ is heated in a flask with a reversed condenser until a clear liquid is obtained; the liquid is evaporated in a stream of CO_2, and the crystals are washed and dried as in 2 (Hurtzig a. Geuther, *A.* 111, 159: $PCl_3 + 3H_2C_2O_4$ $= H_3PO_3 + 3CO + 3CO_2 + 3HCl$).

Properties.—**A colourless, crystalline mass; obtained in transparent crystals by evaporating H_3PO_3Aq *in vacuo* over H_2SO_4. Melts at 74° (H. a. G., *l.c.*); at 70·1° (Thomsen, *l.c.*). Heated above its m.p. decomposes to H_3PO_4 and PH_3. H_3PO_3 is very deliquescent, and oxidises very slowly in air; it acts as an energetic reducing agent. H_3PO_3 is dibasic, forming salts $M^IH_2PO_3$ and $M^I_2HPO_3$.**

Reactions.—1. *Heated* above its m.p., H_3PO_3 decomposes to H_3PO_4 and inflammable P hydride (Vigier, *Bl.* [2] 11, 125; Rose, Davy, *Gm.-K.* 2, 115); according to Hurtzig a. Geuther (*A.* 111, 159) P also separates.—2. Slowly oxidised in *air* to H_3PO_4; dilute solutions of H_3PO_3 are more rapidly oxidised; according to Salzer (*A.* 232, 114), H_3PO_3Aq does not oxidise in air at ordinary temperatures. — 3. Converted into H_3PO_4 by many *oxidisers*, *e.g.* HNO_3Aq, ClAq, BrAq, $KMnO_4Aq$, hypochlorites; with SO_2Aq, H_3PO_4Aq and H_2S are formed along with S (*Gm.-K.* 2, 116).—4. Reduces many *metallic salts in solution*; *e.g.* $AgNO_3Aq$ to Ag, $HgCl_2Aq$ to HgCl and then to Hg, $CuCl_2Aq$ to Cu_2Cl_2 and then to Cu (Rammelsberg, *C. J.* [2] 11, 13).—5. *Nascent hydrogen* forms PH_3 (Dusart, *C. R.* 43, 1126). 6. When crystalline H_3PO_3 is heated with *bromine* to 100° in a sealed tube, H_3PO_4 is formed along with HBr and PBr_3, or the products are HPO_3 and HBr, according to the relative quantity of Br used (Gustavson, *J.* 1867. 139). According to Ordinaire (*C. R.* 64, 363), a crystalline compound is obtained—perhaps bromo-phosphorous acid—by heating H_3PO_3 and Br in the ratio $H_3PO_3 : 4Br$.—7. By heating H_3PO_3 with *iodine* Gustavson (*l.c.*) obtained H_3PO_4, HI, PI_3, and PH_4I.—8. Heated with *phosphorus trichloride* to 170°, P, HCl, and H_3PO_4 or $H_4P_2O_7$ are formed (Geuther, *J. pr.* [2] 8, 359; Kraut, *A.* 158, 332; Gautier, *C. R.* 76, 49). At 79° HCl, $H_4P_2O_7$, and a compound PH_4O are formed, according to Gautier (*l.c.*) (*v.* PHOSPHORUS, COMPOUNDS OF, WITH HYDROGEN AND OXYGEN, p. 134).—9. With *phosphorus pentachloride*, $POCl_3$, HCl, and PCl_3 are produced; and the products of the reaction with *phosphoryl chloride* are PCl_3, HPO_3, and HCl (Geuther, *J. pr.* [2] 8, 359).—10. By *neutralisation with alkalis or alkaline carbonates* salts of the form M_2HPO_3 are produced.

Qualitative distinction between phosphorous and hypophosphorous acids. H_3PO_3Aq reduces $CuSO_4Aq$ to Cu, while the reduction product with H_3PO_2Aq is Cu_2H_2.

PHOSPHITES $M^IH_2PO_3$, $M^I_2HPO_3$, $M^{II}HPO_3$, $M^{III}_2(HPO_3)_3$. These salts are generally obtained by neutralising H_3PO_3Aq by metallic hydroxides or carbonates, or by double decomposition from the alkali salts. They are also formed by the slow oxidation of hypophosphites. Zimmermann's assertion that Na_3PO_3 exists (*A.* 175, 1) has been disproved by Amat (*C. R.* 106, 1351), who has shown that the normal Na salt is Na_2HPO_3. The alkali phosphites are soluble water; most of the others are insoluble. Phosphites are decomposed by heat, generally giving off H or PH_3, and leaving pyrophosphate and phosphide. Solutions of phosphites are scarcely changed in air, but they are readily oxidised to phosphates by energetic oxidisers. The chief memoirs on phosphites are those of H. Rose (*P* 9, 26, 224; 12, 77, 288), Rammelsberg (*P.* 131, 263, 359; 132, 481; *B.* 9, 1577), Kraut (*A.* 177 274), Wurtz (*A.* 58, 65).

Ammonium phosphites $(NH_4)H_2PO_3$ and $(NH_4)_2HPO_3.2H_2O$. The former is obtained by adding NH_3Aq to H_3PO_3Aq till neutral to methyl orange, concentrating, and drying the crystals over H_2SO_4; melts 123°; above 150° gives off

NH_3 and PH_3, and leaves H_3PO_4; absorbs NH_3 at 80°–100°, forming $(NH_4)_2HPO_3$ (Amat, *C. R.* 105, 809). The salt $(NH_4)_2HPO_3.2H_2O$ was obtained by Rose by adding slight excess NH_3Aq to the acid and crystallising; *in vacuo* at ordinary temperature, or at 100° in air, loses NH_3 and gives $NH_4H_2PO_3$ (Amat, *l.c.*).

Barium phosphites. The *normal salt* $BaHPO_3$ is obtained by adding $BaCl_2Aq$ to $(NH_4)_2HPO_3Aq$ (Berzelius, *Gm.-K.* 2, 270), also by boiling $BaHPO_2Aq$ with KOHAq. A crystalline powder; strongly heated gives $Ba_2P_2O_7$, H, and Ba phosphide (*v.* Rammelsberg, *B.* 9, 1577); very slightly sol. water; on boiling with water gives a basic and an acid salt (Dulong, *Gm.-K.* 2. 270). The *acid salts* $BaH_2(HPO_3)_2$, $2BaHPO_3.H_3PO_3.8H_2O$, and $2BaHPO_3.3H_3PO_3.2H_2O$ are said to be formed by the action of H_3PO_3Aq on the normal salt (Rammelsberg, Rose, Wurtz).

Calcium phosphites. $CaHPO_3.xH_2O$; from $CaCl_2Aq$ and $(NH_4)_2HPO_3Aq$ (Wurtz, Rose, Rammelsberg). The *acid salt* $CaH_2(HPO_3)_2.H_2O$ is obtained by dissolving marble in H_3PO_3Aq, and evaporating *in vacuo* (Wurtz).

Cobalt phosphite $CoHPO_3.2H_2O$. A reddish powder, obtained by $CoCl_2Aq + (NH_4)_2HPO_3Aq$, or by dissolving freshly ppd. $CoCO_3$ in H_3PO_3Aq; goes blue at 250° (Rose, Rammelsberg).

Copper phosphite $CuHPO_3.2H_2O$. By double decomposition from $(NH_4)_2HPO_3$ (Rose); also by acting on Cu acetate by H_3PO_3Aq (Wurtz). Unchanged by boiling water (Rammelsberg), but reduced to Cu by boiling with H_3PO_3Aq (Rose).

Lead phosphites. The *normal salt* $PbHPO_3$ is obtained by ppg. Pb acetate by $(NH_4)_2HPO_3Aq$ (Rose). A white powder; heated gives off H and PH_3, leaving $Pb_2P_2O_7$ and Pb phosphide. Insol. water (Amat, *C. R.* 110, 901). By adding NaH_2PO_3Aq to excess of $Pb2NO_3Aq$, the compound $PbHPO_3.Pb(NO_3)_2$ is obtained (Amat, *l.c.*). The *acid salt* $PbH_2(HPO_3)_2$ is formed by dissolving the normal salt in very conc. H_3PO_3Aq, and drying the crystals at 100°; with water gives $PbHPO_3$ and H_3PO_3Aq (Amat, *l.c.*).

Magnesium phosphite $MgHPO_3.xH_2O$. By ppg. boiling $MgSO_4Aq$ by Na_2HPO_3Aq (Rammelsberg). Forms a *double salt* $Mg_3(NH_4)_2(HPO_3)_4.16H_2O$ (Rammelsberg, Rose).

Manganese phosphite $MnHPO_3.H_2O$. A reddish powder; very slightly sol. water, more sol. solutions of Mn salts; loses H_2O at 200°. From NH_4 salt and a Mn salt; or by dissolving $MnCO_3$ in H_3PO_3Aq, and adding Na_2CO_3 till ppn. begins, but not enough to remove acid reaction (Rose, Rammelsberg).

Potassium phosphites. The *normal salt* K_2HPO_3 is formed from H_3PO_3Aq and KOHAq or K_2CO_3Aq; semi-crystalline, syrup-like mass; very hygroscopic; insol. alcohol (Wurtz, Rose). The *acid salt* $K_2HPO_3.2H_3PO_3$ was obtained by Wurtz (*A.* 58, 63). Amat (*C. R.* 106, 1351) obtained the *acid salt* KH_2PO_3 by adding KOHAq or K_2CO_3Aq to H_3PO_3Aq till neutral to methyl orange, concentrating, and cooling.

Sodium phosphites. The *normal salt* $Na_2HPO_3.5H_2O$ is obtained by dissolving H_3PO_3 in an excess of NaOHAq, and evaporating *in vacuo* (Amat, *C. R.* 108, 403). Zimmermann (*A.* 175, 1) supposed that Na_3PO_3 is formed under these conditions. Na_2HPO_3 melts at 53°; heat of solution at 13·5° = −4600 (Amat, *C. R.* 110, 191). Dehydrated by drying *in vacuo*, and then at 150° (A., *l.c.*). The *acid salt* $2NaH_2PO_3.5H_2O$ is produced by making H_3PO_3Aq neutral to methyl orange by NaOHAq or Na_2CO_3Aq, concentrating, and cooling. Melts 42°; dehydrated by long heating at 100°; heated above 130° forms $Na_4P_2O_5$; very sol. water; heat of solution at 15° = −10,600 (Amat, *C. R.* 106, 1351).

Zinc phosphite $2ZnHPO_3.5H_2O$; from $ZnSO_4Aq$ and ammoniacal solution of PCl_3 (Rose); also from PCl_3Aq and ZnO (Rammelsberg).

The following phosphites have also been described:—$Di_2(HPO_3)_3$ (Frerichs a. Smith, *A.* 191, 331); $Fe_2(HPO_3)_3.9H_2O$ (Rose, Rammelsberg); $La_2(HPO_3)_3$ (F. a. S., *l.c.*); $SnHPO_3$ (Rose). Phosphites of Al, Be, Bi, Cd, Cr, ferrous Fe, Hg, Ni, and Sr have also been prepared, but their compositions are somewhat doubtful (*v.* especially Rose, *l.c.*).

HYPOPHOSPHORIC ACID AND SALTS $H_4P_2O_6$; $M^IH_3P_2O_6$, $M^I_2H_2P_2O_6$, $M^I_3HP_2O_6$, $M^I_4P_2O_6$, $M^{II}H_2P_2O_6$, $M^{II}_2P_2O_6$. When sticks of P are partly covered with water and left for some time in a large vessel, an acid liquid is obtained; this liquid was formerly called Pelletier's phosphatic acid (P., *Crell. Ann.* 1796 [2] 447). Dulong (*A. Ch.* [2] 2, 141) found 47·8 p.c. P and 52·2 p.c. O in this substance, and supposed it to be P_2O_9. In 1856 Pagel (*J. pr.* 69, 24) showed that the acid liquid contained phosphoric and phosphorous acids; and in 1877 Salzer (*A.* 187, 322) proved the presence of small quantities of a new acid to which he gave the composition nH_2PO_3 and the name *hypophosphoric acid.* The acid has been found to be tetrabasic, hence the formula is written $H_4P_2O_6$. The hypophosphates are generally formed directly from the acid, or by double decomposition from the alkali salts. The hypophosphates are more stable than the hypophosphites and phosphites; normal salts pass into phosphates by taking up O; they are decomposed by heating strongly, giving of PH_3 or H, and leaving phosphate and phosphide.

HYPOPHOSPHORIC ACID $H_4P_2O_6$. Melts at c. 55° (Joly, *C. R.* 102, 110). Heat of solution = 3,850 (J., *l.c.*).

Formation.—1. Along with H_3PO_3 and H_3PO_4, by the slow oxidation of P in moist air (Salzer, *A.* 187, 322; 194, 28; 211, 1; 232, 114, 271).—2. The Ag salt is formed by oxidising P by dilute HNO_3Aq in presence of $AgNO_3$ (Philipp, *B.* 18, 749); also by reacting on H_3PO_3Aq with $AgNO_3Aq$ (Sänger, *A.* 232, 1); and the Cu salt by reacting on P with $Cu(NO_3)_2Aq$ (Corne, *J. Ph.* [5] 6, 123).

Preparation.—Sticks of P are placed in glass tubes narrowed at the lower end; these are arranged inside a funnel, which is placed in the mouth of a bottle containing a little water; the bottle is set in a basin, and the whole is covered with a large bell-jar open at the top. The apparatus is placed in a cool place (best in a cellar) for some weeks or months; according to Joly (*C. R.* 101, 1058), from $\frac{1}{7}$ to $\frac{1}{5}$ of the P is oxidised to $H_4P_2O_6$ if the process is conducted in winter, and not more than $\frac{1}{10}$ in summer.

The acid liquid is mixed with a cold conc. solution of Na acetate, the ppd. $Na_2H_2P_2O_6.6H_2O$ is collected, washed with a *very little* cold water, then dissolved in water (sol. in c. 45 parts cold water), and ppd. by Pb acetate; the $Pb_2P_2O_6$ is collected, washed with cold water, suspended in water, and decomposed by H_2S; the filtrate is evaporated at a low temperature—not exceeding 30°—or *in vacuo* over H_2SO_4, until crystals of $H_4P_2O_6$ are deposited. Joly (*C. R.* 101, 1058, 1148) heats to boiling the acid liquid obtained by oxidising P, as described above, adds Na_2CO_3 till nearly neutral to methyl orange, and crystallises by concentration; he washes the crystals of $Na_2H_2P_2O_6.6H_2O$ with cold water, and recrystallises from hot water, dissolves in hot water, adds an equivalent of $BaCl_2$ in hot water, washes the ppd. $BaH_2P_2O_6$, decomposes it by an equivalent of H_2SO_4 diluted with its own weight of water, filters after two or three days, and evaporates *in vacuo* over H_2SO_4. Drawe (*B.* 21, 3401) carries out the oxidation of P in presence of Na acetate solution.

Properties.—Small colourless crystals, which melt at c. 55° (Joly, *C. R.* 102, 110); very hygroscopic; solution is unchanged in air at ordinary temperatures. Heated to c. 70° suddenly decomposes to H_3PO_3 and HPO_3 (J., *l.c.*); at c. 120° gives $H_4P_2O_7$ and P hydride (J., *C. R.* 102, 760).

Reactions and Combination.—1. *Heat* decomposes $H_4P_2O_6$ (*v. supra*).—2. *Not oxidised* by such *oxidisers* as H_2O_2Aq, ClAq, CrO_3Aq, $HgCl_2Aq$, &c.—3. *Not reduced* by such *reducers* as SO_2Aq, H_2S, or Zn and H_2SO_4Aq.—4. *Potassium permanganate* is slowly reduced in the cold, quickly on heating, by $H_4P_2O_6Aq$ to which H_2SO_4Aq has been added.—5. Heated with *nitric acid*, H_3PO_4Aq is formed.—6. Heated with *dilute sulphuric acid*, H_3PO_3Aq and H_3PO_4Aq are produced.—7. *Silver nitrate* solution gives a white pp., which does not blacken in light and is soluble in warm HNO_3Aq (1:1).—8. By evaporating $H_4P_2O_6Aq$ till the liquid had the composition $P_2O_4.6H_2O$, and then placing over H_2SO_4 *in vacuo*, Joly (*C. R.* 101, 1058; 102, 110) obtained crystals of the *hydrate* $H_4P_2O_6.2H_2O$, melting at 62°–62·5°.

HYPOPHOSPHATES. $M^IH_3P_2O_6$, $M^I_2H_2P_2O_6$, $M^I_3HP_2O_6$, $M^I_4P_2O_6$, $M^{II}H_2P_2O_6$, $M^{II}_2P_2O_6$. These salts have been examined chiefly by Salzer (*A.* 187, 322; 194, 28; 211, 1; 232, 114, 271), and crystallographically by Haushofer a. Fresenius (*Z. K.* 1, 257, 620; 3, 605; 6, 113; 9, 254). The hypophosphates are much more stable towards oxidisers than the hypophosphites or phosphites. They reduce $KMnO_4Aq$ very slowly in the cold after addition of H_2SO_4Aq, and give white pp. with $AgNO_3Aq$ unchanged in light.

Ammonium hypophosphates. The *normal salt* $(NH_4)_4P_2O_6.xH_2O$ is obtained by adding excess of NH_3Aq to the acid; on drying, loses NH_3 and effloresces. The *acid salts* $(NH_4)_2H_2P_2O_6$ and $(NH_4)_3HP_2O_6$ are formed, the former by boiling a solution of the normal salt, the latter by adding the proper quantity of $H_4P_2O_6$ to the former salt.

Barium hypophosphates. The *normal salt* $Ba_2P_2O_6$ is obtained from $BaCl_2Aq$ and $Na_4P_2O_6Aq$; the *acid salt* $BaH_2P_2O_6.2H_2O$ is formed from $NaH_2P_2O_6Aq$ and $BaCl_2Aq$ (*v.* Joly, *C. R.* 101, 1058).

Cadmium hypophosphate $Cd_2P_2O_6.2H_2O$; and the *double salt* $CdNa_2P_2O_6.6H_2O$ (Drawe, *B.* 21, 3401).

Calcium hypophosphates $Ca_2P_2O_6$ and $CaH_2P_2O_6.6H_2O$.

Cobalt hypophosphate $Co_2P_2O_6.8H_2O$; and the *double salt* $2CoNa_2P_2O_6.3H_2O$ (Drawe, *l.c.*).

Copper hypophosphate $Cu_2P_2O_6.6H_2O$ (Drawe, *l.c.*).

Lead hypophosphate $Pb_2P_2O_6$.

Magnesium hypophosphates $Mg_2P_2O_6.12H_2O$ and $MgH_2P_2O_6.4H_2O$; and the *double salt* $Mg(NH_4)_2P_2O_6.6H_2O$.

Nickel hypophosphate $Ni_2P_2O_6.12H_2O$; and the *double salt* $NiNa_2P_2O_6.12H_2O$ (Drawe, *l.c.*).

Potassium hypophosphates $K_4P_2O_6.8H_2O$, $K_3HP_2O_6.3H_2O$, $K_2H_2P_2O_6$, and $KH_3P_2O_6$.

Silver hypophosphate $Ag_4P_2O_6$ (*v.* Philipp, *B.* 14, 749).

Sodium hypophosphates. The *acid salt* $Na_2H_2P_2O_6.6H_2O$ is obtained by slowly oxidising P in moist air, and adding Na acetate solution as described under *Preparation of hypophosphoric acid* (p. 154); sol. 45 parts cold, or 5 parts boiling, water; insol. alcohol; on strongly heating gives off H and P hydride and leaves $NaPO_3$. The *normal salt* $Na_4P_2O_6.10H_2O$ is obtained by adding an equivalent of Na_2CO_3 to $Na_2H_2P_2O_6Aq$; sol. c. 30 parts cold water, much more sol. hot water; solution reacts alkaline, and gives a mixture of salts on evaporation. The *acid salt* $Na_3HP_2O_6.9H_2O$ is formed by mixing the Na_2 and Na_4 salts in the ratio $Na_2H_2P_2O_6 : Na_4P_2O_6$. The *acid salt* $NaH_3P_2O_6.2H_2O$ is formed by adding the proper quantity of $H_4P_2O_6Aq$ to $Na_2H_2P_2O_6$. For reaction of the Na salts with different indicators *v.* Joly, *C. R.* 101, 1058.

Another *acid salt* $Na_5H_3(P_2O_6)_2.20H_2O$ is said to be formed by adding rather more than one molecular weight NaOH to $4Na_2H_2P_2O_6.6H_2O$.

Zinc hypophosphate $Zn_2P_2O_6.2H_2O$ (Drawe, *l.c.*).

PYROPHOSPHITES. In 1887 Amat (*C. R.* 106, 1400) showed that when $2NaH_2PO_3.5H_2O$ is heated to 160° it loses $6H_2O$ and gives the salt $Na_2H_2P_2O_5$. A few other salts of the form $M_2H_2P_2O_5$ have been obtained, but the acid has not been isolated. When the Ba salt is decomposed by an equivalent of H_2SO_4Aq, the solution shows the reactions of pyrophosphites, but the pyrophosphite gradually changes to phosphite (Amat, *C. R.* 108, 1056). The pyrophosphites in solution slowly change to phosphites, the more rapidly the more conc. the solution and the higher the temperature; the presence of an acid, *e.g.* H_2SO_4, greatly quickens the rate of change (A., *l.c.*). Addition of NaOHAq to a boiling solution of the Na salt produces Na_2HPO_3 (A., *C. R.* 106, 1400). Pyrophosphites in very dilute solutions give no pp. with $Pb(NO_3)_2Aq$ until boiled; phosphites give an immediate white pp.; this reaction serves as a qualitative test for the two classes of salts (A., *C. R.* 110, 901).

Lead pyrophosphite $PbH_2P_2O_5$ is obtained by heating $PbH_2(HPO_3)_2$ in a dry vacuum to c. 140°

It is insol. water, but is gradually changed by water to H_3PO_3Aq and $PbHPO_3$ (A., *C. R.* 110, 901).

Sodium pyrophosphite $Na_2H_2P_2O_5$ is formed by heating $2NaH_2PO_3.5H_2O$, which has been partially dehydrated *in vacuo*, to c. 160°. V. sol. water; solution changes to NaH_2PO_3Aq, but by careful evaporation *in vacuo* over H_2SO_4 crystals of $Na_2H_2P_2O_5$ can be again obtained (A., *C. R.* 108, 1056). Presence of acid hastens the change to NaH_2PO_3Aq; this change is also effected by adding NaOHAq to boiling $Na_2H_2P_2O_5Aq$. Heat of solution of $Na_2H_2P_2O_5 = 300$ (A., *C. R.* 110, 191).

For *thiopyrophosphites* $M_4P_2S_5$ and *thio-oxy-pyrophosphites* $M_4P_2O_3S_2$ and $M_4P_2O_4S$ *v.* Phosphorous sulphide, *Reactions* 7 and 8, p. 146; and for *selenopyrophosphites* $M_4P_2Se_5$ *v.* Phosphorous selenide, p. 145). M. M. P. M.

PHOSPHORYL COMPOUNDS. Compounds of the radicle PO are generally called *phosphoryl compounds*; and compounds of the radicle PS are often called *thio-phosphoryl compounds.* These compounds are described in this Dictionary as *phosphorus oxychloride, oxyfluoride, sulphochloride*, &c. The phosphoryl compounds are $PO(NH_2)_3$, $POCl_3$, $POBr_3$, $POBrCl_2$ and $POBr_2Cl$, POF_3, $PO.NH.NH_2$, PON. The thiophosphoryl compounds are $PS(NH_2)_3$, $PSCl_3$, $PSBr_3$, $PSBrCl_2$, PSF_3. The compounds $P_2O_3Cl_4$ and $P_2S_3Br_4$ are sometimes called *pyrophosphoryl chloride* and *pyrothiophosphoryl bromide*, respectively.

M. M. P. M.

(α)-PHOSPHOTOLUIC ACID

$C_6H_3Me(PO_3H_2).CO_2H$ [3:4:1]. *Toluphosphinic acid.* [262°]. Formed by oxidising *m*-xylene phosphonic acid with hot alkaline $KMnO_4$ (Weller, *B.* 20, 1723; 21, 1492). Prisms, v. sol. hot water, v. e. sol. alcohol. Yields HPO_3 and *m*-toluic acid when heated.—PCl_5 yields oily $C_6H_3Me(POCl_2).COCl$. — PbHA‴ aq: needles (from dilute HOAc).—Ag_3A'''.

(β)-Phosphotoluic acid

$C_6H_3Me(PO_3H_2).CO_2H$ [5:3:1]. [220°]. Formed by oxidising *s-m*-xylene phosphonic acid (Weller). Yields HPO_3 and *m*-toluic acid on heating. —Ag_3A''': amorphous pp.

Chloride $C_6H_3Me(POCl_2).COCl$. (249° at 147 mm.). Oil.

Phosphotoluic acid

$C_6H_3Me(PO_3H_2).CO_2H$ [4:*x*:1]. [278°]. Formed by oxidising *p*-xylene phosphonic acid. Needles, decomposed by heat into HPO_3 and *p*-toluic acid.

Chloride $C_6H_3Me(POCl_2).COCl$. [62°]. Crystalline mass.

PHOTO-CHEMISTRY *v. Influence of light on chemical change*, under Chemical change, vol. i. p. 748; also next article (Photographic chemistry); also *Optical methods*, a section of Physical methods, in this volume, p. 221.

PHOTOGRAPHIC CHEMISTRY. The photographic processes at present in use depend primarily upon the photo-chemical decomposition of certain metallic compounds in the presence of suitable oxidisable substances known as sensitisers. Broadly speaking, the photo-decomposable compound may be regarded from a chemical point of view as an oxidising agent, of which the oxidising power is only brought into action under the stimulus of light, th associated compound or sensitiser being at th same time oxidised by the oxygen or halogen thus liberated. Very many metallic compounds are thus susceptible to the influence of light, although only a few of these have up to the present time found practical application. The nature of the chemical change undergone in such cases may be well illustrated by the action of light upon ferric salts. An aqueous solution of ferric chloride, for example, is not acted upon by light because the associated substance (water) is not capable of reacting with the liberated chlorine with sufficient rapidity; in other words, water is incapable of acting as a sensitiser towards ferric chloride. But if some oxidisable organic compound is present, light then reduces the ferric to the ferrous salt. Thus an alcoholic solution of ferric chloride exposed for a few minutes to sunlight gives a blue colouration with potassium ferricyanide, indicating the presence of a ferrous salt, probably formed according to the equation: $Fe_2Cl_6 + C_2H_6O = Fe_2Cl_4 + C_2H_4O + 2HCl$. In a similar way paper coated with a solution of ferric chloride can be used to obtain prints, because the paper (or the size contained in it) plays the part of a sensitiser, and the exposed portions of the surface thus become covered with a ferrous instead of a ferric compound, and on brushing over with a solution of ferricyanide the print is developed in blue. In practice ferric oxalate is found to be the most sensitive ferric compound, the organic acid being the sensitiser: $Fe_2(C_2O_4)_3 = Fe_2(C_2O_4)_2 + 2CO_2$.

Although the chemical action of light upon metallic compounds generally is of the nature of reduction, and is accompanied by the simultaneous oxidation of the compound which plays the part of a sensitiser, there are many instances in which light promotes the action of atmospheric oxygen or other oxidising agent. Thus potassium iodide may be kept in a dry atmosphere in the dark for any length of time without undergoing change, but in the presence of light and moisture photo-chemical oxidation takes place, and the salt becomes alkaline:

$$4KI + 2H_2O + O_2 = 4KOH + 2I_2.$$

Action of light upon silver salts. Of all known metallic compounds the salts of silver are the most sensitive to the action of light, and these salts accordingly form the basis of all existing photographic processes. The most familiar instance of the photo-decomposition of a silver salt is the well-known change in colour experienced by silver chloride on exposure to light, a phenomenon which has been familiar since the sixteenth century. The other silver haloids, viz. the bromide and iodide, are also decomposed by light, the latter only in the presence of some sensitiser capable of rapidly absorbing iodine. The absolute sensitiveness of the silver haloids cannot be estimated by the degree of darkening on exposure, because the product of photo-decomposition is of a darker colour in the case of the chloride than in the case of the bromide, and the product is darker in the case of the bromide than in that of the iodide. The sensitiveness is actually determined by two conditions, viz. the nature of the sensitiser and the state of molecular aggregation of the silver haloid. In most of the negative processes ow in use, the bromide or iodide, or a mixture f the two, forms the sensitive surface.

The nature of the chemical change undergone n exposure to light has not yet been completely lucidated for all the silver haloids. It is known hat the chloride loses chlorine on exposure, and hat the darkened product contains less chlorine han the unaltered haloid. It is as yet uncerain whether the halogen which is given off is lways evolved in the free state or not; it has been hown, however, that silver chloride on exposure o light gives off a gas which rapidly turns potasium iodide and starch paper blue (Meldola, *Chemistry of Photography*, p. 66). It is stated y many writers that the darkened product is a ubchloride formed according to the equation: $AgCl = 2Ag_2Cl + Cl_2$. There is, however, no satisactory evidence of the existence of such a subalt, and it seems more probable that the dark roduct consists of an oxychloride, in combinaion, or admixture, with unaltered chloride. According to some analyses by Hodgkinson, the xychloride has the formula Ag_4OCl_2. In support f this conclusion it is found that the chloride loes not darken in absolutely dry air, unless apour of mercury is present (Abney), thus naking it appear that moisture is essential for he decomposition. The latest investigation of he action of light on AgCl by Baker (*C. J.* 61, 28) confirms the view that the darkened product ontains an oxychloride; Baker gives the formula Ag_2ClO. A second, white, oxychloride also robably exists (Richardson, *C. J.* 59, 536). Silver chloride is thus analogous to cuprous or hallous chloride, which also darken under the nfluence of light, with the formation of what are believed to be oxychlorides. Whatever may be the chemical composition of the darkened product, it is probable that the bromide and iodide give rise to the formation of analogous compounds, and that the invisible picture in the older processes is formed of these products on a background of unaltered haloid. The undeveloped image on modern dry plates, coated with gelatin emulsion, may, however, have a different composition, owing to the presence of the organic sensitiser.

Photosalts of silver. These are coloured forms of the silver haloids prepared by the action of certain reducing agents upon silver compounds, and the subsequent conversion of the partially reduced products into the haloids by treatment with the necessary acids. These compounds are of a red or purple colour, and have been shown to contain less halogen than the unaltered haloids. It is probable that they consist of physical combinations of the oxyhaloid or hydrated oxyhaloid with the unaltered haloid; their discoverer (Carey Lea) has shown that they closely resemble, if they are not actually identical with, the products of the photo-chemical reduction of the silver haloids. If this be admitted, it follows that the product which forms the photographic image can be prepared by purely chemical methods (*Am. S.* 1887).

Photographic processes. In all photographic processes the first operation is the exposure of a surface coated with a uniform film of the silver haloid to the image formed by a lens in a camera. The image thus depicted on the film is invisible, in the first place because of the very slight difference in colour between the product of photo-reduction and the unaltered haloid, and in the next place because the short period of exposure does not produce a sufficient quantity of the product of reduction to render the latter visible. The invisible image thus consists of a layer of reduction-product of infinitesimal thinness, and the picture is afterwards made visible by the deposition of metallic silver on this reduction-product by the application of certain solutions known as 'developers,' the chemical action of which will be described subsequently.

Daguerreotype. This process is historically interesting as having been the first method of photography with a silver salt successfully applied to the production of a picture from the image formed in a camera. It takes its name from Daguerre, who announced the discovery in 1839. The process is no longer used; it has been superseded by more rapid methods. In order to prepare a Daguerreotype plate, a plate of copper is silvered, and the polished surface is exposed to the vapour of iodine and bromine alternately. The sensitive film is therefore a mixture of silver iodide and bromide. Silver iodide can act to some extent as its own sensitiser, but the substratum of metallic silver is chiefly effective in this capacity as it is capable of rapidly absorbing the halogen liberated by the action of light upon the sensitive surface. The invisible image is developed by exposure to the vapour of mercury, which condenses on the product of reduction but not on the unaltered haloid.

Collodion processes. In these processes the sensitive film consists of a silver haloid formed by double decomposition in collodion as a vehicle. Collodion is a solution of the tri- and tetranitrate of cellulose (collodion pyroxyline) in alcohol and ether (*v.* vol. i. p. 716), and on coating a glass plate with this solution the solvents evaporate and leave a uniform layer of the pyroxyline attached to the plate. Some soluble iodide, NH_4I or CdI_2, sometimes mixed with a small quantity of a bromide, is first dissolved in the collodion, the plate is coated with this salted collodion, and when dry is sensitised by immersion in a silver nitrate solution. The sensitive surface in this process is therefore a silver haloid wetted with a film of silver nitrate solution, the latter playing the part of a sensitiser by absorbing the liberated halogen: $3I_2 + 6AgNO_3 + 3H_2O = 5AgI + AgIO_3 + 6HNO_3$. By washing out the soluble salts after the plate has been removed from the silver solution the sensitiveness is practically destroyed, because the pyroxyline by itself has no halogen-absorbing power. On drying such a washed plate, and then coating it with a solution of tannin or some organic sensitiser, the sensitiveness is partially restored. Plates thus treated can be used in the dry state, and dry-plate photography by this method was made practically successful in 1861 by Colonel Russell.

Emulsion processes. All the photographic methods at present in vogue are comprised in this group. The silver haloid is precipitated in a finely divided state in some vehicle, usually gelatin, and the plates coated with this emulsion are allowed to dry and are then ready for use. A brief description of a method for preparing a gelatin emulsion will suffice to make clear the general mode of procedure. The soluble bromide (potassium or ammonium), sometimes mixed with a little iodide, is dissolved in water, together with a certain quantity of the gelatin, and to this solution the calculated quantity of silver nitrate (previously dissolved in water) is added little by little with constant agitation. The quantities are so adjusted as to leave no excess of silver nitrate. The silver haloid is by this means precipitated in an extremely fine state of division in the viscid gelatin solution, with which it forms an emulsion. A stronger solution of gelatin is then mixed intimately with the first dilute emulsion, and the whole is heated on a water-bath for about an hour to become 'ripened.' When cold, the semi-solid emulsion is washed by immersion in a fine state of division in cold water, so as to remove all soluble salts (nitrates formed by double decomposition, excess of soluble haloids, &c.). The washed emulsion is then mixed with the necessary quantity of strong gelatin solution to reduce it to the required consistency, and the plates are coated and allowed to dry. Many variations in the details of mixing have been introduced, but these involve no change in principle. Ripening can also be effected at ordinary temperatures by the action of ammonia.

Ripening of emulsions. The process of ripening above referred to is necessary in order to increase the sensitiveness of the silver haloid, since the latter when first precipitated is comparatively insensitive. The increase of sensitiveness is no doubt due, partially if not wholly, to a physical change in the state of molecular aggregation of the silver haloid, as it is accompanied by a growth in the size of the particles and by a change in the absorption spectrum, the unripened emulsion transmitting more of the red rays, and, therefore, absorbing less of this part of the spectrum, than the ripened emulsion. The extreme sensitiveness of the emulsions at present in use is thus due in great measure to the circumstance that the haloid is rendered sensitive to a much wider range of spectral colours than is the case with ordinary silver bromide precipitated in a non-emulsifying medium. The increased sensitiveness of a ripened emulsion may also be ascribed, in part, to the formation of an actual compound of the silver haloid with the gelatin or some constituent thereof (Meldola, *Cantor Lectures on Photographic Chemistry*, 1891. 20, 21).

Development of the photographic image. *Acid development.* In the wet collodion process the image is developed by the application of a solution of ferrous sulphate mixed with acetic acid and alcohol (to insure uniformity of flow). The film being already wet with silver nitrate solution, the action of the developer is simply to reduce this salt according to the reaction: $6AgNO_3 + 6FeSO_4 = 2Fe_2(SO_4)_3 + Fe_2(NO_3)_6 + 6Ag$. Metallic silver is thus contained as a potential deposit in the mixed solutions, but its precipitation is retarded by the acetic acid, which plays the part of what is technically called a 'restrainer.' The finely-divided metal is deposited only on the product of photo-decomposition (the invisible picture), the density of the deposit being proportional to the amount of decomposition on each portion of the sensitive surface. The image thus continues to gain in density as long as there is silver to feed it, so that the picture is built up by accretion and is raised in relief on the surface of the film. If the film is treated with dilute nitric acid after development, the picture is dissolved off, leaving the film in the same condition as before exposure, thus proving that the image is purely superficial. The ferrous sulphate developer, which acts in the manner described, is a type of the class of acid developers.

Alkaline development. Gelatin emulsions contain no excess of silver nitrate, so that the foregoing process of development is inapplicable. The gelatin itself, being a bromine absorbent, is in this case the sensitiser. Development is effected in modern processes by means of an alkaline or neutral solution of some reducing agent, usually an easily oxidisable organic compound, such as ammonium pyrogallate, first introduced by Colonel Russell in 1862. In this method the developer acts directly as a reducing agent upon the product of photo-reduction, replacing the latter by its equivalent of metallic silver. The image at the same time gains in density by the further reduction of those portions of the unaltered silver haloid which are in immediate contact with the nascent silver being generated by the developer; the action is probably electrolytic, since the image goes on increasing in density as long as the developer can exert a reducing action. A very small amount of the silver deposit may also be due to the reduction of the minute quantity of silver actually dissolved out of the film by the ammonia or other solvent in the developer. In alkaline development the main portion of the silver image is therefore built up by growth from the silver haloid in the film, and after development the image can be dissolved out by dilute nitric acid, leaving its impression sunk in the gelatin, instead of leaving a plane surface, as in the case of a collodion picture similarly treated.[1] The developers belonging to this class are all strong reducing agents capable of directly reducing the silver haloids, so that the action has to be moderated by means of restrainers, potassium bromide being generally employed for this purpose. The restraining action of this salt is probably due to its tendency to form a double potassio-silver bromide, which is more stable than the silver bromide itself. In addition to ammonium pyrogallate several other developers acting in a similar manner have come into use. Of these may be mentioned potassio-ferrous oxalate (Carey Lea, 1877), which acts according to the equation: $3Br_2 + 6FeC_2O_4 + 3K_2C_2O_4 = 3Fe_2(C_2O_4)_3 + 6KBr$. The bromine in this case is derived primarily from the reduction-product. Other developers coming under this category are an alkaline solution of hydroquinone (quinol), hydroxylamine, phenylhydrazine, and an alkaline salt of amido-β-naphthol-monosulphonic acid (Meldola, *C. J.* 39, 47), introduced by Andresen (*Eikonogen*). Among the most recently introduced developers are certain amido-phenols, amido-phenols and carboxylic acids, and their alkyl derivatives, known as '*amidol*,' '*metol*,' &c. Those which contain the basic and hydroxyl substituents in the para- position seem to be the most effective (Hauff, *Engl. Patents* [1891] 15, 431; 20, 690).

---

[1] An able investigation of the connection between the density of the deposit of reduced silver and the period of exposure, &c., is published by Harter a. Driffield (*S. C. I.* 9, 455; 10, 100; *v.* also other papers in same volume; also Armstrong, *Conference No. of Journ. of the Camera Club*, 1892, and discussion in same journal, July 1892).

In the processes of alkaline development the gelatin itself also acts the part of a restrainer by preventing too intimate a contact between the reducing solution and the silver haloid. Any viscous substance exerts this protecting influence (sugar, glycerin, &c.), and such compounds are sometimes called *physical restrainers*, to distinguish them from chemical restrainers, such as the acid in the ferrous sulphate developer or the potassium bromide in alkaline developers. A developer of very great reducing power is for this reason available in dry plate photography, and upon this fact largely depends the extreme sensitiveness of modern processes.

Development by vapour. The Daguerreotype picture was developed by exposure to mercury vapour, this metal having the property of condensing on the product of photo-reduction (the invisible image) but not on the unaltered silver haloid. It is not known whether the combination of the mercury with the reduction-product is of a chemical or physical nature. This method of development is at present the sole representative of its class.

Fixing the picture. The image developed by the foregoing methods is always on a background of unchanged silver haloid, which must obviously be removed before the picture can be exposed to white light. In the early days of photography strong solutions of potassium, sodium, or ammonium chloride were used as fixing agents, these salts having the property of forming soluble double salts with the silver haloids. The action of these salts was, however, very imperfect, and a certain amount of undissolved silver haloid was always left in the film, which led on exposure to the gradual darkening and obliteration of the whole picture. Potassium cyanide has since been employed, this salt forming with the silver haloid an extremely soluble double cyanide: $AgBr + 2KCN = AgK(CN)_2 + KBr$. The fixing agent now generally preferred is sodium thiosulphate (Sir J. Herschel, 1839); this salt, if used in excess, forming the extremely soluble sodio-silver thiosulphate $Ag_2Na_4(S_2O_3)_3, 2aq$: $2AgBr + 3Na_2S_2O_3 = Ag_2Na_4(S_2O_3)_3 + 2NaBr$. If the fixing solution is dilute, the insoluble $NaAgS_2O_3$ is formed, which remains in the film and spoils the picture: $AgBr + Na_2S_2O_3 = AgNaS_2O_3 + NaBr$. After immersion in the fixing bath, the soluble salts are removed by thorough washing in a stream of water.

Intensification, and reduction, of density. In cases where the image is wanting in density through under-exposure, bad light, insufficient development, &c., a process of intensification is resorted to. The process as applied to modern dry plates consists in substituting for the silver, of which the image is composed, some denser deposit. Thus, by immersing a negative in a solution of mercuric chloride, the image is bleached by conversion into a mixture of mercurous and silver chlorides: $2Ag + 2HgCl_2 = 2AgCl + Hg_2Cl_2$. By treating this mixture with a solution of potassio-ferrous oxalate the image is restored in silver and mercury, and thus in a condition of increased density: $2AgCl + Hg_2Cl_2 + 4FeC_2O_4 + 2K_2C_2O_4 = 2Ag + 2Hg + 2Fe_2(C_2O_4)_3 + 4KCl$. Many other intensifiers are known, some acting by simple substitution, such as auric or platinic chloride: $6Ag + 2AuCl_3 = 2Au + 6AgCl$, or $4Ag + PtCl_4 = Pt + 4AgCl$; others giving rise to a mixture of products together denser than the original deposit, e.g. lead or uranium ferricyanide: $4Ag + 2Pb_3Fe_2(CN)_{12} = Ag_4Fe(CN)_6 + 3Pb_2Fe(CN)_6$. In cases where too dense an image has been obtained, and it is desired to thin it down, a reducing solution is applied; the chemical principle may be described as a conversion of the metallic silver into some compound which can be simultaneously removed by a solvent such as sodium thiosulphate. Thus a mixture of potassium ferricyanide with thiosulphate is often used for gelatino-bromide plates: $4Ag + 2K_6Fe_2(CN)_{12} = Ag_4Fe(CN)_6 + 3K_4Fe(CN)_6$. The silver ferro-cyanide is dissolved off by the thiosulphate, as fast as formed: $Ag_4Fe(CN)_6 + 6Na_2S_2O_3 = 2Ag_2Na_4(S_2O_3)_3 + Na_4Fe(CN)_6$. When the necessary reduction of density has been attained, the action of the solution is stopped by washing the film with water.

Reversal of the photographic image and allied phenomena. Any influence which affects a sensitive film in a way similar to the action of light gives rise to a developable image. Thus mechanical pressure-marks produced by rubbing a film with a glass rod can be developed by ferrous oxalate &c., so as to show a corresponding set of dark streaks. It is probable that the friction in this case induces a minute amount of chemical change between the sensitive haloid and its associated sensitiser (gelatin, &c.), this small quantity of reduction-product being afterwards exaggerated by the cumulative action of the developer. Whether the compound resulting from this mechanical action is identical with that produced by the action of light is at present uncertain, but the associated sensitiser appears to be as essential to the success of the phenomenon in this case as in the ordinary formation of the invisible picture by the action of light. The sensitiser, as has already been explained, is an *essential* part of any photographic system, and this is best shown by the so-called 'reversal' of the photographic image by over-exposure or other means. It has been found that a very strong light allowed to act on a sensitive film for too long a period gives a weaker image on development than is produced with a shorter exposure, and that under some circumstances the image is even 'reversed,' *i.e.* the high lights come out lighter, on development, than the shadows. The explanation of this phenomenon is probably to be found in the circumstance that while the silver haloid is losing halogen under the influence of light, the sensitiser is simultaneously becoming halogenised, so that when the charge of halogen in the latter exceeds a certain amount the chemical change sets in in a reversed direction, *i.e.* the halogenised sensitiser begins to re-halogenise the product of photo-decomposition and thus to destroy the invisible image. That this explanation is, in the main, correct in principle, is shown by the fact that the most sensitive processes are just those which are most prone to give rise to reversal, because it is in such films that the sensitiser becomes most rapidly halogenised. A preliminary exposure to diffused light also promotes reversal, because this imparts a certain initial charge of halogen to the sensitiser. Then, again, oxidising agents favour reversal, because these lessen the halogen-absorbing power of the sensitiser; on the other hand, reducing agents prevent reversal, because they retard or prevent the halogenation of the sensitiser. Thus plates exposed in ozone or in solutions of $K_2Cr_2O_7$ and $K_2Mn_2O_8$ are easily reversed, while nitrites, sulphites, &c., prevent reversal (Abney). Atmospheric oxygen in many cases probably plays a part in the process by assisting in the liberation of halogen from the sensitiser. Thus, by way of illustration, if a plate be given a preliminary exposure to diffused light, and be then coated with a solution of potassium iodide, a completely reversed image can be obtained on exposure in the camera and development. The chemical reaction is in this case: $4KI + 2H_2O + O_2 = 2I_2 + 4KOH$. The iodine is here absorbed by the reduction-product, and thus reverses the picture; the surface of the film is in fact the sensitiser in this case, and the potassium iodide is the photo-sensitive compound.[1]

Waterhouse has recently found that a small quantity of a thio-carbamide added to the developer produces a 'reversed' image (*Photo. News*, 1890. 727, 743, 804; *v.* also *Journ. of Camera Club*, July 1892; also Rawlins, *S. C. I.* 10, 18).

Printing processes. It is obvious that the photographic image, after normal development, represents the object with its lights and shadows reversed, *i.e.* the picture is a negative one. A positive print is obtained by exposing suitable sensitive surfaces under such a negative.

Silver prints. A very general method of obtaining silver prints depends upon the use of a sensitive surface (usually paper) consisting of a mixture of silver chloride and an organic compound of silver with albumen, this surface being obtained by first coating the substratum with a solution of albumen containing ammonium chloride, and then (when dry) floating on a solution of silver nitrate. The printing is carried on to the required depth of colour, and the visible print consists of the reduction-products of silver chloride, and of the organic silver compound, which is also susceptible of photo-reduction. To correct the reddish colour of these mixed reduction-products the print is 'toned' by immersion in a solution of auric chloride, kept neutral by the addition of sodium carbonate, acetate, or phosphate, chalk, borax, &c. The function of these salts is to neutralise the hydrogen chloride liberated by the reduction of the auric chloride by the reducing compounds which constitute the picture. The gold is thus precipitated in a state of fine division only on the products of photo-decomposition (the picture), and imparts the desired tone. The accumulation of acid in the toning bath retards the precipitation of gold, and the deposit is not of a good tone; hence the necessity for the presence of one of the salts referred to. The unaltered silver chloride &c. is removed by fixing with thiosulphate, and washing. In some recent processes the albumenised silver paper is replaced by paper coated with gelatino-bromide or chloride emulsion, a short exposure being given, and the invisible (positive) picture being developed in the usual manner.

Printing with iron and uranium salts. Ferric and uranic salts in the presence of organic sensitisers become reduced on exposure to light, and the ferrous or uranous compounds thus formed can be developed by treatment with potassium ferricyanide or other salts which give coloured products with the ferrous or uranous, but not with the unreduced, salts. Thus paper coated with ferric oxalate gives a faint image of the ferrous salt, which comes out as a deep-blue print on development with ferricyanide: $6FeC_2O_4 + 2K_6Fe_2Cy_{12} = 2Fe_3(Fe_2Cy_{12}) + 6K_2C_2O_4$. Many printing processes depending upon the foregoing principles have come into use, and will be found described in works on practical photography.

Platinotype. Prints in finely-divided platinum can be obtained by exposing a surface coated with a mixture of ferric oxalate and potassium chloroplatinite under a negative. The ferrous salt thus produced does not react with the chloroplatinite till the picture is developed by immersion in a solution of potassium oxalate, which dissolves the ferrous oxalate, with the formation of a double salt, which simultaneously reduces the chloroplatinite:
$3K_2PtCl_4 + 6FeC_2O_4$
$= 3Pt + 2Fe_2(C_2O_4)_3 + Fe_2Cl_6 + 6KCl$. The soluble salts are then removed by washing with dilute hydrochloric acid, and finally with water.

Pigment printing. A mixture of gelatin with potassium dichromate undergoes a chemical change on exposure to light, in the course of which the dichromate is reduced and the gelatin at the same time becomes insoluble in water. The chemical composition of this insoluble gelatin is unknown, but it appears to contain an oxide of chromium as an essential constituent (Eder). Many printing processes are based upon this property of gelatin, such, for example, as the so-called carbon and pigment prints, in which the finely divided carbon or pigment is intimately mixed with the gelatin solution and the mixture sensitised by the addition of dichromate. After exposure under a negative the picture is developed by warm water, which dissolves away those portions of the tissue unacted upon by light. Many of the photo-mechanical printing processes depend also on this property of gelatin.

Photo-etching processes. When a layer of asphalt or bitumen is spread over a surface and exposed under a design, those portions of the film which are acted on by light become insoluble in hydrocarbon oils, so that the design can be developed by such solvents, and the surface, if of metal, can be converted into a printing block by etching with acid. The change experienced by the bitumen is probably the result of photo-chemical oxidation. The processes based on this property are much in vogue at the present time under various modifications. This action of light upon bitumen furnished the earliest successful permanent reproduction of the camera picture (Joseph Nicephore Niepce, 1824).

---

[1] Potassium bromide similarly acts as a reversing agent though to a less extent. It is for this reason that every trace of this salt has to be washed out of a gelatino-bromide emulsion after the process of ripening, since the presence of the soluble bromide materially diminishes the sensitiveness of the emulsion.

Bibliography.—It has not been considered advisable in the present article to give the authority for every statement, as most of the results achieved by photographers are to be found in publications rarely consulted by chemists. The following general works contain practically all that is known of photographic chemistry at the present time:—Robert Hunt, *Researches on Light*, 2nd edit., 1854; E. Becquerel, *La Lumière*, Paris, 1867; J. W. Draper, *Scientific Memoirs*, a collection of reprints, 1878; J. M. Eder, *Ueber die Reactionen der Chromsäure u. der Chromate auf Gelatine, Gummi, Zucker, &c.* Wien, 1878; J. M. Eder, *Ausführliches Handbuch der Photographie*, Halle, 1884 9; H. W. Vogel, *La Photographie des Objets Colorés avec leurs Valeurs Réelles*, Paris, 1887; Pizzighelli and Hübl, *La Platinotypie*, Paris, 1887; W. de W. Abney, *Treatise on Photography*, 5th edit., 1888; by the same author, *Instructions in Photography*, and *Photography with Emulsions*; Chapman Jones, *Introduction to the Science and Practice of Photography*, 1888; R. Meldola, *The Chemistry of Photography*, 1889; H. W. Vogel, *Handbuch der Photographie*, Berlin, 1890-1. R. M.

PHOTOSANTONIN *v.* SANTONIN.

PHRENOSIN $C_{41}H_{79}NO_8$. A substance occurring, according to Thudichum (*J. pr.* [2] 25, 19), in the brain.

PHTHALACENE $C_{21}H_{16}$. [173°]. Formed by reduction of phthalacone carboxylic ether with HI and P at 170° (Gabriel, *B.* 17, 1390). Crystals (from HOAc). Yields $C_{21}H_{15}Br$ [184°], which is oxidised by $K_2Cr_2O_7$ and HOAc to $C_{21}H_{13}BrO$ [c. 200°]. Fuming HNO_3 and HOAc yield di-nitro-phthalacene, which separates from hot nitro-benzene in yellow needles. $K_2Cr_2O_7$ and HOAc oxidise phthalacene to 'phthalacene oxide' $C_{21}H_{14}O$ [211°-214°], which yields an oxim $C_{21}H_{14}(NOH)$ [266°].

PHTHALACENIC ACID $C_{20}H_{15}.CO_2H$. [247°]. Formed by heating phthalacene-oxide with soda-lime (Gabriel, *B.* 17, 1399). Crystals.—A'Ag.

PHTHALACONE CARBOXYLIC ACID $C_{21}H_{11}O_2(CO_2H)$. [281°]. Formed by dissolving its ether in conc. H_2SO_4 and pouring into water (Gabriel, *B.* 17, 1389). Minute yellow needles, sol. hot alcohol. The acid yields a dioxim $C_{21}H_{11}(NOH)_2CO_2H$ [273°] and the salts KA'aq and NaA'aq. Zinc-dust and NaOHAq yield a tetrahydride $C_{22}H_{16}O_4$, melting above 280°, which gives AgA', crystallising in needles.

Ethyl ether EtA'. [211°]. A product of the action of phthalic anhydride and NaOAc on acetoacetic ether at 140°. Yellow needles, sol. hot HOAc. Yields a di-nitro- derivative [above 280°] and a dioxim $C_{21}H_{11}(NOH)_2CO_2Et$ [264°]. Zinc-dust and HOAc reduce it to the white tetrahydride $C_{21}H_{13}(OH)_2CO_2Et$ [213°].

PHTHAL-ALCOHOL *v.* DI-OXY-XYLENE.

PHTHALALDEHYDIC ACID $C_8H_6O_3$ *i.e.* $CHO.C_6H_4.CO_2H$ [1:2]. [97°]. Formed, together with $C_{16}H_{10}O_5$ [221°], by heating α-bromo-phthalide with water (Racine, *B*, 19, 778; *A.* 239, 78; *C. R.* 106, 947). Formed also by boiling penta-ω-chloro-*o*-xylene with water (Colson a. Gautier, *Bl.* [2] 45, 509). V. sol. water, alcohol, and ether. Reduces ammoniacal $AgNO_3$. Phenyl-hydrazine yields $C_{14}H_{10}N_2O$ [105°]. Alcoholic NH_3 forms $C_{24}H_{18}N_2O_6$ [187°], while an alcoholic solution of aniline gives $C_{14}H_{11}NO_2$ [174°]. Ac_2O at 200° forms $CHO.C_6H_4.CO_2Ac$ [60°-63°]. Urea forms $NH_2.CO.N:CH.C_6H_4.CO_2H$ [240°].—CaA'_2 2aq.—AgA': slender needles.

Ethers MeA'. [44°].—EtA'. [66°].

Anhydride $C_{16}H_{10}O_5$. [221°]. Got by heating the acid with bromo-phthalide.

Oxim $CH(NOH).C_6H_4.CO_2H$. [120°]. Formed by adding hydroxylamine hydrochloride to a cold aqueous solution of the acid. In an alcoholic solution the product is  $C_6H_4\langle\begin{smallmatrix}CO.O\\CH:N\end{smallmatrix}$ [120°], which is converted by heat first into $CN.C_6H_4.CO_2H$ and then into phthalimide (Allendorff, *B.* 24, 2346, 3264).

Isomeride *v. p*-ALDEHYDO-BENZOIC ACID.

Diphthalaldehydic acid *v.* DI-PHTHALYL-LACTONIC ACID.

PHTHALAMIC ACID *v.* PHTHALIC ACID.

PHTHALAMIDE *v.* PHTHALIC ACID.

ISOPHTHALAMIDINE $C_8H_{10}N_4$ *i.e.* $C_6H_4(C(NH).NH_2)_2$ [1:3]. Formed from $C_6H_4(C(NH).OEt)_2$ and alcoholic NH_3 (Luckenbach, *B.* 17, 1432). Small needles, insol. benzene and ether, v. sol. alcohol and water. Its aqueous solution soon decomposes, giving off NH_3.—$B''H_2Cl_2$: needles, v. sol. water.—$B''H_2PtCl_6$.—$B''H_2SO_4$.—$B''2HNO_3$.—$B'HNO_3$: needles (Grabowski, *A.* 265, 168).—$C_6H_4(NAg.NH_2)_2$.

ISOPHTHALAMIDOXIM $C_8H_{10}N_4O_2$ *i.e.* $C_6H_4(C(NOH).NH_2)_2$. [193°]. Formed from $C_6H_4Cy_2$ [1:3] and hydroxylamine (Goldberg, *B.* 22, 2976). Prisms (from alcohol) containing ½aq ?, v. sol. hot water.

Phthalanil *v. Phenylimide* of PHTHALIC ACID.

PHTHALBENZO-TOLUIDE *v. Phthalyl*-AMIDO-TOLYL PHENYL KETONE.

PHTHAL-*o*-CYANO-BENZYL-IMIDE *v.* *o*-CYANO-BENZYL-PHTHALIMIDE.

PHTHALEÏNS. Colouring-matters obtained by condensation of phthalic anhydride with phenols (*e.g.* PHENOL-PHTHALEÏN and FLUORESCEÏN). They may be reduced to colourless 'phthalins,' which are re-oxidised by air to phthaleïns.

PHTHALIC ACID $C_8H_6O_4$ *i.e.* [1:2] $C_6H_4(CO_2H)_2$. Mol. w. 166. [184°] (Lossen, *A.* 144, 76); [203°] (Ador, *A.* 164, 230; Baeyer, *A.* 269, 184). S. ·54 at 14°; 18 at 99° (Graebe, *A.* 238, 321); S. (alcohol) 10 at 15° (Bourgoin, *Bl.* [2] 29, 247); S. (ether) ·684 at 15°. H.C. 771,600. H.F. 187,400 (Stohmann, *J. pr.* [2] 43, 540); 153,000 (von Rechenberg). S.H. (from 75° to 119°) ·256 (Hess, *A. Ch.* [2] 35, 410).

Formation.—1. By the action of nitric acid on naphthalene, naphthalene dichloride, alizarin, purpurin, munjistin, naphthoquinone, *o*-toluic acid (Laurent, *A. Ch.* [2] 61, 113; Marignac, *A.* 42, 215; Schunck, *A.* 66, 197; Wolff a. Strecker, *A.* 75, 12, 25; Stenhouse, *A.* 130, 334; Liebermann a. Dittler, *B.* 6, 94 ; Piccard, *B.* 12, 579; Beilstein a. Kurbatoff, *A.* 202, 215).—2. By the action of various oxidising agents on naphthalene (Lossen, *A.* 144, 71; Hermann, *Z.* [2] 4, 551; Depouilly, *C. R.* 56, 82; Häussermann, *D. P. J.* 223, 310).—3. A product of the action of MnO_2 and H_2SO_4 on benzene (Carius, *Z.* [2] 4, 705; *A.* 148, 60).—4. By oxidising *o*-toluic acid with $KMnO_4$ (Weith, *B.* 7, 1057).—5. By oxidising isoquinoline with alkaline $KMnO_4$ (Hoogewerff a. Van Dorp, *R. T. C.* 4, 285).—6. By heating salicylic acid with H_2SO_4 and K_4FeCy_6 (Guyard, *Bl.* [2] 29, 247).—7. By heating resorcin or salicylic acid with formic acid and H_2SO_4 (G.).—8. By the action of a hot solution of cuprous potassium cyanide upon *o*-diazobenzoic chloride (from anthranilic acid), and subsequent saponification of the product (Sandmeyer, *B.* 18, 1499).

Properties.—Trimetric plates. Yields an anhydride when heated. Insol. chloroform.

Reactions.—1. Distillation with *lime* yields benzoic acid and benzene.—2. *Sodium-amalgam* reduces it to a dihydride.—3. *Chromic acid mixture* oxidises it to CO_2 (Fittig, *A.* 156, 242).—4. The acid aniline salt $A''H(NH_3Ph)$ of *ortho*-phthalic acid loses H_2O when its aqueous solution is boiled, phenyl-phthalimide crystallising out. The *para-* and *meta-* phthalic acids do not react in this way; the reaction therefore serves as a means of separating ordinary phthalic acid from its isomers (Michael a. Palmer, *B.* 19, 1376; *Am.* 9, 202).

Salts.—$(NH_4)HA''$: prisms, v. sol. water.—$NaHA''2aq$: prisms (Wislicenus, *A.* 242, 89).—Na_2A'': pearly plates.—K_2A''.—$CaA''aq$.—$BaH_2A''_2$: prisms (Hermann, *A.* 151, 78).—BaA'': v. sl. sol. water (Carius, *A.* 148, 64).—$Ba_4A''_3O$: monoclinic prisms.—$CuA''aq$.—PbA''.—Ag_2A'': crystalline pp.—Aniline salt: needles [146°] (Clarke, *B.* 12, 1066).

Di-methyl ether Me_2A'' (280° i.V.) at 734 mm. (Graebe, *B.* 16, 860). H.F. 164,600 (Stohmann, *J. pr.* [2] 40, 353).

Mono-ethyl ether $EtHA''$. Formed by heating phthalic anhydride with absolute alcohol at 100° (Michael, *Am.* 1, 413). Liquid, m. sol. water. Decomposed by heat into phthalic anhydride and alcohol.—$Ba(EtA'')_2$.—$AgEtA''$.

Di-ethyl ether Et_2A''. (295° cor.). Got by passing HCl into an alcoholic solution of phthalic acid (Graebe a. Born, *J.* 1866, 411). Formed also from phthalyl chloride and alcohol. Liquid. Not attacked by hydroxylamine (Jeaurenaud, *B.* 22, 1273). When warmed with NaOEt and EtOAc it yields the compound $C_6H_4<\substack{CO\\CO}>CH.CO_2Et$ [75°-78°] (Wislicenus, *A.* 246, 349). PCl_3 followed by sodium malonic ether forms the acid $C_{21}H_{16}O_{10}$ [c. 180°] (Zelinsky, *B.* 20, 1010).

Phenyl ether Ph_2A''. [70°]. Formed by heating phthalyl chloride with phenol (Schreder, *B.* 7, 704; von Gerichten, *B.* 13, 419). Colourless crystals.

Anhydride $C_8H_4O_3$ *i.e.* $C_6H_4<\substack{CO\\CO}>O$. Mol. w. 148. V.D. 5·26 (calc. 5·13) (Troost, *C. R.* 89, 351). [128°]. (284·5° i.V.). H.C.p. 784,000. H.F. 106,000 (Stohmann, *J. pr.* [2] 40, 139). Formed by heating phthalic acid alone or with AcCl (Laurent; Anschütz, *B.* 10, 326). Formed also by the action of lead nitrate on phthalyl chloride (Lachovitch, *B.* 17, 1283). Long needles, v. sol. alcohol and ether, sl. sol. cold water. *Reactions.*—1. When heated with *phenols* it yields phthaleïns, with elimination of water (Baeyer, *B.* 7, 968).—2. Heated with NaOAc and HOAc it yields phthalyl-acetic acid $C_{10}H_6O_4$, while *phenyl-acetic acid* gives benzylidene-phthalide. Phenyl-acetonitrile gives rise to $C_6H_4<\substack{CO.O\\C:CPh.CN}$ [165°], and *isobutyric acid* and $ZnCl_2$ at 250° give a ketone $C_{11}H_{10}O_2$ [96°]. 3. Boiling with NaOAc and *phenoxyacetic acid* yields $C_6H_4:C_2O_2:CH.OPh$ [143°] while *p-tolyl-oxy-acetic acid* and sodium acetate give rise to $C_6H_4:C_2O_2:CH.OC_6H_4Me$ [174°] (Gabriel, *B.* 14, 922).—4. *Acetoacetic ether* gives $C_6H_3Bz_3$ and phthalacone carboxylic ether.—5. On heating with *succinic acid* and *sodium succinate* it yields CO_2 and $C_{18}H_{10}O_4$ [above 300°].—6. *Di methyl-quinoline* and zinc chloride at 200° give $C_6H_4:C_2O_2:C_{11}H_9N$ [238°] (Beyer, *J. pr.* [2] 33, 407).—7. *Ethenyl-amido-phenyl-mercaptan* and $ZnCl_2$ at 200° give $C_6H_4<\substack{N\\S}>C.CH<\substack{CO\\CO}>C_6H_4$ crystallising in yellow needles [above 320°] (Jacobson, *B.* 21, 2630).—8. *Cyanethine* forms, on heating, $C_9H_{13}N_2.N:C_2O_2:C_6H_4$ [128°] (E. von Meyer, *J. pr.* [2] 39, 262).—9. Coal-tar *picoline* and zinc chloride at 200° form pyrophthalone $C_8H_4O_2:CH.C_5H_4N$ [above 260°] (Jacobsen a. Reimer, *B.* 16, 2604) crystallising from alcohol in yellow plates.—10. *Benzene* and $AlCl_3$ yield *o*-benzoyl-benzoic acid, and other aromatic hydrocarbons act in like manner (Friedel a. Crafts, *C. R.* 92, 833).—11. *Benzyl chloride* and *zinc-dust* at 75° yield $C_{50}H_{46}$ (?) [73°] (Wislicenus, *A.* 248, 68).—12. On heating with *amines* and *amides*, phthalic anhydride yields derivatives of the imide and amide of phthalic acid; thus acetamide yields phthalimide and HOAc, while ethylamine yields ethyl-phthalimide. Secondary amines form derivatives of the amic acid and of the amide (Piutti, *A.* 227, 181; *G.* 16, 1, 251).—13. *Amido-acids* are converted by phthalic anhydride into their phthalyl derivatives (Reese, *A.* 242, 1).—14. On fusion with *zinc-dust* phthalic anhydride gives diphthalyl. Zinc-dust and HOAc yield a mixture of phthalide, diphthalyl dihydride  $C_6H_4<\substack{CO.OO.CO\\CH—HC}>C_6H_4$, [229°] and  $\substack{O.CO\\CO_2H.C_6H_4.CH_2.CH}>CH_4$ [199°], which is reduced by HIAq to $C_2H_4(C_6H_4.CO_2H)_2$ (Wislicenus, *B.* 17, 2178).—15. *Tri-amido-phenol* (picramic acid) forms $(C_8H_4O_2:N)_3C_6H_2.OH$ [above 300°] converted by potash into the compound $(CO_2H.C_6H_4.CO.NH)_3C_6H_2OH$ [above 300°], from which nitric acid produces the quinone $(C_8H_4O_2:N)_2C_6H_2O_2$ [277°] reduced by SO_2 to $(C_8H_4O_2:N)_2C_6H_2(OH)_2$ [above 310°] (Piutti, *G.* 16, 254).

Chloride $C_6H_4<\substack{CCl_2\\CO}>O$. *Phthalyl chloride.* [0°] (Wischin, *A.* 143, 259). (275°) at 726 mm. S.G. $\frac{20}{4}$ 1·4089. $\mu_a = 1·569$ (Brühl, *A.* 235, 14). Formed by heating phthalic acid with PCl_5 for 2 hours at 190° (H. Müller, *Z.* 1863, 257; Graebe, *A.* 238, 320). Oil, absorbs moisture from the air, forming phthalic anhydride. Slowly converted into phthalic acid by water or Na_2CO_3Aq. Reduced by zinc and HClAq to phthalide. Sodium-amalgam and HOAc form $C_6H_4(CH_2.OH)_2$. PCl_5 forms two isomeric chlorides $C_6H_4<\substack{CCl_2\\CCl_2}>O$ and $C_6H_4<\substack{CCl_3\\COCl}$, one melting at 88° and boiling at 275°, the other melting at 47° and boiling at 262°; both are converted by aniline into $C_6H_4<\genfrac{}{}{0pt}{}{C(NPh)}{CO}>NPh$ [153°] (von Gerichten, *B.* 13, 417; Claus, *B.* 19, 1188). Excess of PCl_5 yields chloro-benzoic acid, CCl_4, and other products (Claus). Aqueous NH_3 forms $C_8H_4O_2(NH_2)_2$ [90°] not identical with phthalamide, but converted by HClAq into $C_8H_4O_2(NH)$ [145°] which is changed by fusion into the isomeric phthalimide [228°] (Auger, *A. Ch.* [6] 22, 303; *cf.* Kuhara, *Am.* 3, 26). Dry NH_3 acting on the benzene solution behaves in like manner. Hydroxylamine yields $C_6H_4{:}C_2O_2{:}NOH$ [230°] (*v.* vol. ii. p. 738). *o*-Amido-phenyl mercaptan hydrochloride forms $C_{20}H_{12}N_2S_2$ [112°] (Hofmann, *B.* 13, 1233). $ZnMe_2$ forms $C_{10}H_{10}O_2$ [68°] (240°) (Rjasantzeff, *Bl.* [3] 1, 166). $ZnEt_2$ followed by water gives, in like manner, $C_{12}H_{14}O_2$ [54°] (250°).

Semi-nitrile v. o-CYANO-BENZOIC ACID.

Amic acid $C_6H_4(CO.NH_2).CO_2H$. *Phthalamic acid.* [c. 140°] (Auger); [149°] (Aschan, *B.* 19, 1401). Formed by heating phthalic anhydride with alcoholic NH_3 or phthalimide with baryta-water. Prepared by evaporating phthalic anhydride with NH_3Aq, and decomposing the resulting ammonium salt by HCl (Auger, *Bl.* [2] 49, 349). Prisms, sl. sol. water, v. sol. alcohol. Converted by heat into phthalimide, and by hot water into hydrogen ammonium phthalate. Excess of HClAq forms phthalic acid.—NH_4A'.—KA'.—BaA'_2.—BaA'_2 aq.—AgA': needles, v. sl. sol. water (Landsberg, *A.* 215, 197).

Isoamyl-amic acid
$C_6H_4(CO_2H).CO.NHC_5H_{11}$. *Isoamyl-phthalamic acid.* [115°]. Formed by warming isoamyl-phthalimide with KOHAq (Neumann, *B.* 23, 998). Crystalline pp.—AgA'.

Phenyl-amic acid
$C_6H_4(CO_2H).CO.NHPh$. *Phenyl-phthalamic acid. Phthalanilic acid.* [192°]. Got by boiling phenyl-phthalimide with NH_3Aq and some alcohol (Laurent a. Gerhardt, *A. Ch.* [3] 24, 188). Plates, sl. sol. cold water, v. sol. alcohol.

Phenyl-ethyl-amic acid $C_{16}H_{15}NO_3$ *i.e.* $C_6H_4(CO_2H).CONPhEt$. *Phenyl-ethyl-phthalamic acid.* Got by dissolving phthalic anhydride in ethyl-aniline (Piutti, *G.* 13, 545; *A.* 227, 185). Heavy oil, v. sl. sol. water.

Di-phenyl-amic acid
$C_6H_4(CO_2H).CONPh_2$. *Di-phenyl-phthalamic acid.* [148°]. Made from diphenylamine and phthalic anhydride (P.). Hard prisms, sl. sol. ether, v. sol. alcohol.—AgA'.

o-Tolyl-amic acid
$C_6H_4(CO_2H).CONHC_6H_4Me$. Got by boiling *o*-tolyl-phthalimide with NH_3Aq (Kuhara, *Am.* 9, 51). Needles.—$Ag_2C_{15}H_{11}NO_3$: pp.

m-Methyl-benzyl-amic acid
$C_6H_4(CO_2H).CO.NHCH_2C_6H_4Me$. [131°]. Got from *m*-xylyl-phthalimide and caustic soda (Brömme, *B.* 21, 2700). Needles, sol. alcohol.—AgA': white pp.

ψ-Cumyl-amic acid
$C_6H_4(CO_2H).CO.NHC_6H_2Me_3$. *Phthal-ψ-cumidic acid.* [179°]. Needles, v. sol. alcohol, sl. sol. ether (Fröhlich, *B.* 17, 1808).

Naphthyl-amic acids
$C_6H_4(CO_2H).CO.NHC_{10}H_7$. The (α)- acid [185°] is got from (α)-naphthyl-phthalimide. The (β)-acid crystallises from alcohol in tables (Piutti, *G.* 15, 480).

Phenyl-oxy-ethyl-amic acid
$C_6H_4(CO_2H).CO.NH.C_2H_4.OPh$. [125°]. Formed by warming phenyl-oxyethyl-phthalimide with KOHAq (Schmidt, *B.* 22, 3255).

p-Tolyl-oxy-ethyl-amic acid
$C_6H_4(CO_2H).CO.NH.CH_2.CH_2.O.C_6H_4Me$. [137°]. Formed from the corresponding imide which is got by heating potassium phthalimide with $C_6H_4Me.OC_2H_4Br$ (Schreiber, *B.* 24, 191).

Phenyl-amido-phenyl-amic acid
$C_6H_4(CO_2H).CO.NH.C_6H_4.NHPh$. [120°-130°]. Powder (Gabriel, *B.* 22, 2223).

Benzoylethyl-amic acid
$C_6H_4(CO_2H).CO.NH.CH_2.CH_2Bz$. *Propiophenone-phthalamic acid.* [140°]. Made from the imide (Schmidt, *B.* 22, 3251). Needles.—AgA': pp.

Di-sulphido-di-ethyl-amic acid
$(C_6H_4(CO_2H).CO.NH.CH_2.CH_2)_2S_2$. [130°]. Formed from sulphocyano-ethyl-phthalimide and (10 p.c.) KOHAq (Coblenz, *B.* 24, 2131). Scales. HClAq at 180° forms $S_2(C_2H_4NH_2)_2$.

Uramic acid $C_6H_4(CO_2H).CONH.CO.NH_2$. *Phthaluric acid.* S. 3·5 at 99°. Formed by heating phthalic anhydride with urea at 115° (Piutti, *A.* 214, 19; *G.* 12, 173). Silvery scales, sol. alcohol. May be converted by $POCl_3$ into  $C_6H_4<\genfrac{}{}{0pt}{}{CO.NH}{CO.NH}>CO$, which yields $AgC_9H_5N_2O_3$.

Salts.—NaA' 2aq.—BaA'_2.—AgA': needles.

Thio-uramic acid
$C_6H_4(CO_2H).CO.NH.CSNH_2$. [172°]. Got by heating phthalic anhydride with thio-urea (P.). Silvery needles (from alcohol).—BaA'_2 7aq.

s-Amide $C_6H_4(CO.NH_2)_2$. *Phthalamide.* [220°] (Bülow, *A.* 236, 188 Formed from phthalimide and cold NH_3Aq (Aschan, *B.* 19, 1399). Minute crystals, insol. cold water, alcohol, and ether. Boiling water converts it into phthalimide. Alkaline KOBr at 80° forms  $C_6H_4<\genfrac{}{}{0pt}{}{CO.NH}{NH.CO}$ (Hoogewerf a. Van Dorp, *R. T. C.* 10, 9).

u-Amide  $C_6H_4<\genfrac{}{}{0pt}{}{C(NH_2)_2}{CO}>O$. [c. 90]. Formed from phthalyl chloride and NH_3Aq (Auger, *A. Ch.* [6] 22, 304). Long transparent prisms, v. sol. water, sol. hot alcohol. $AgNO_3$ ppts. $C_8H_4O_2NAg$ in white lustrous scales, NH_3 being eliminated.

Phenyl-ethyl-amide
 $C_6H_4<\genfrac{}{}{0pt}{}{C(NPhEt)_2}{CO}>O$. [141°]. Formed by heating the ethyl-aniline salt of phenyl-ethyl-phthalamic acid above 200° (Piutti, *G.* 13, 547; *A.* 227, 187). Prisms, insol. water, sol. alcohol and ether. Not attacked by KOHAq, but split up by potash-fusion into phthalic acid and ethyl-aniline.

Di-phenyl-amide $C_6H_4{:}C_2O_2(NPh_2)_2$. '*Di-phenylamine-phthaleïn.*' [288°]. Formed from phthalyl chloride and diphenylamine (Lellmann, *B.* 15, 830). Formed also by boiling phthalic anhydride with diphenylamine (P.). Needles (from alcohol). H_2SO_4 containing HNO_3 forms an intense violet solution.

m-Phenylene-diamide
$C_8H_4O_2{:}N_2H_2{:}C_6H_4$. [179°]. Formed, together with $(C_8H_4O_2{:}N)_2C_6H_4$ [252°], by fusing *m*-phenylene-diamine with phthalic anhydride (Biedermann, *B.* 10, 1160). Nodules.

p-Phenylene-diamide $C_6H_4:C_2O_2:N_2H_2:C_6H_4$. [182°]. Converted by warming with dilute HClAq into a base $C_{31}H_{28}N_6O_4$ and $(C_6H_4:C_2O_2:N)_2C_6H_4$ [295°] (Biedermann, *B.* 10, 1163).

u-Imide  $C_6H_4{<}\substack{C(NH)\\CO—}{>}O$. *u-Phthalimide.* [c. 145°]. Formed by the action of HClAq on the *u*-amide (Auger). Slender needles, exactly resembling the *s*-imide, into which it changes when heated. Differs from the *s*-imide by decomposing moist $BaCO_3$ in the cold, hence it may possibly be *o*-cyano-benzoic acid.

s-Imide  $C_6H_4{<}\substack{CO\\CO}{>}NH$. *Phthalimide.* [228°]. Formed by heating $C_6H_4(CO_2H)(CO_2NH_4)$ or $C_6H_4(CO_2H).CONH_2$ (Laurent, *A.* 41, 110; *A. Ch.* [2] 61, 121; [3] 23, 119; Lansberg, *A.* 215, 181). Got also by heating the *u*-imide, and by the action of $CuCy_2$ and KCy on *o*-diazobenzoic acid (Sandmeyer, *B.* 18, 1499). Six-sided prisms (from ether). May be sublimed. Reduced by tin and HCl to phthalidine $C_8H_6O(NH)$ (Graebe, *B.* 17, 2598). When distilled with steam over heated zinc-dust it yields $C_{15}H_{11}N$ [100°] (Gabriel, *B.* 13, 1684). Boiling Ac_2O forms $C_6H_4:C_2O_2:NAc$ [132°–135°] (Aschan, *B.* 19, 1398). Amyl alcohol and Na reduce phthalimide to *o*-methyl-benzyl-amine (Bamberger, *B.* 21, 1888). Yields benzonitrile when distilled with lime (Reese, *A.* 242, 5). Alkaline KOBr at 80° forms *o*-amido-benzoic acid (Hoogewerff a. Van Dorp, *R. T. C.* 10, 8) $C_8H_4O_2NK$. Formed from phthalimide and alcoholic potash (Cohn, *A.* 205, 301; Gabriel, *B.* 20, 2225). Plates, converted into potassium phthalamate by boiling water. Converted by alkyl iodides into alkylphthalimides. [1:2]$C_6H_4(CH_2Br)_2$ gives rise to $C_6H_4(CH_2.N:C_8H_4O_2)_2$ [253], while the *m*-isomeride melts at 237°. Reacts with epichlorhydrin, forming $C_8H_4O_2N.C_3H_5O$ [204°] (Goedeckemeyer, *B.* 21, 2689) with (α)-dichlorhydrin, forming $(C_8H_4O_2:N.CH_2)_2CH.OH$ [204°], and with γ-bromobutyronitrile, forming $C_8H_4O_2N.CH_2.CH_2.CH_2.CN$ [81·5°] (Gabriel, *B.* 22, 224, 3337; 23, 1771).—$C_8H_4O_2NNa$. — $(C_8H_4O_2N)_2Mg$: white pp. — $(C_8H_4O_2N)_2Ba$ 4aq: plates. — $(C_8H_4O_2N)_2Hg$. — $(C_8H_4O_2N)_2Cu$ aq. — $(C_8H_4O_2N)_2Cu$ 4aq. — $C_8H_4O_2NAg$ ½aq: cheesy pp.

Imidoxim $C_8H_6N_2O_2$ *i.e.*  $C_6H_4{<}\substack{C(NOH)\\CO}{>}O$. [250°]. Formed by heating *o*-cyano-benzoic ether with an alcoholic solution of hydroxylamine at 90° for a long time (Müller, *B.* 19, 1498). Needles (from dilute alcohol), insol. benzene. Boiling with HClAq and $FeCl_3$ converts it into phthalimide.

Methyl-imide $C_8H_4O_2:NMe$. [132°]. (286°). Formed from potassium-phthalimide and MeI at 150° (Graebe, *B.* 17, 1174; *A.* 247, 302). Needles, reduced by tin and HCl to C_9H_9NO [120°] (300°), which yields a gold salt [196°].

Ethyl-imide $C_6H_4:C_2O_2:NEt$. *Ethylphthalimide.* [79°]. (282°) at 726 mm. Formed by distilling a solution of phthalic anhydride in aqueous ethylamine; and formed also from potassium phthalimide and EtI (Michael, *B.* 10, 1645; Graebe, *A.* 247, 302; Wallach a. Kamenski, *B.* 14, 171). Needles. Br at 140° forms $C_{10}H_6Br_3NO_2$ [c. 189°].

Bromo-ethyl-imide $C_8H_4O_2:N.CH_2.CH_2Br$. [83°]. Formed from potassium phthalimide and $C_2H_4Br_2$ (Gabriel, *B.* 20, 2225; 21, 566; 22, 1137). Needles. Converted by aniline into phenyl-amido-ethyl-phthalimide [100°], and by *p*-toluidine into both $(C_8H_4O_2:N.C_2H_4)_2NC_6H_4Me$ [200°] and $C_8H_4O_2:N.C_2H_4.NHC_6H_4Me$ [96°]. ψ-Cumidine forms $C_8H_4O_2:N.C_2H_4.NHC_6H_2Me_3$ [146°], while (α)- and (β)-naphthylamines form compounds $C_8H_4O_2:N.C_2H_4.NHC_{10}H_7$ [158°] and [141°] respectively (Newman, *B.* 24, 2196). Potassium sulphocyanide forms $C_8H_4O_2:N.C_2H_4SCy$ [108°] (Coblenz, *B.* 24, 2131).

Sulphydro-ethyl-imide $C_8H_4O_2:N.C_2H_4SH$. [77°]. Formed from the bromo-ethyl-imide and KSH at 100°. Converted by NaOEt and glycollic chlorhydrin into syrupy $C_8H_4O_2:N.C_2H_4.S.C_2H_4OH$, whence $POCl_3$ forms $C_8H_4O_2:N.C_2H_4.S.C_2H_4Cl$ [77°], while $POBr_3$ forms $C_8H_4O_2:N.C_2H_4.S.C_2H_4Br$ [90°]. Reacts with $C_8H_4O_2:N.C_2H_4Br$ and NaOEt, forming $(C_8H_4O_2:N.C_2H_4)_2S$ [129°], which is oxidised by bromine water to the corresponding sulphoxide [191°], and by chromic acid to the sulphone [256°]. Iodine in alcoholic solution forms $(C_8H_4O_2:N.C_2H_4)_2S_2$ [139°], whence $B''H_2Cl_2$ [203°] (Gabriel, *B.* 24, 1122, 3098).

n-Propyl-imide $C_8H_4O_2:NPr$. [66°]. (283°). Crystals (Gabriel, *B.* 24, 3105).

Isopropyl-imide [85°]. (273°).

β-Bromo-propyl-imide $C_8H_4O_2:N.CH_2.CHBr.CH_3$. [105°]. Formed from the allylimide and HBr (Seitz, *B.* 24, 2627). Converted by KSH into $C_8H_4O_2:N.CH_2.CHMe.SH$ [88°], which is oxidised in alcoholic solution by I to $(C_8H_4O_2:N.CH_2.CHMe)_2S$ [161°]. Potassium sulphocyanide forms $C_8H_4O_2:N.CH_2.CHMe.SCy$ [89°–93°].

γ-Bromo-propyl-imide $C_8H_4O_2:N.CH_2.CH_2.CH_2Br$. [73°]. Got from trimethylene bromide and potassium phthalimide (Gabriel, *B.* 21, 2671; 23, 90). Needles (from ligroïn). Converted by sodium ethyl-malonic ether into $C_8H_4O_2:N.C_3H_6.CEt(CO_2Et)_2$ [62°], and by sodium benzyl-malonic ether into $C_8H_4O_2:N.C_3H_6.C(CH_2Ph)(CO_2Et)_2$ [c. 110°] (Aschan, *B.* 23, 3692). Potassium sulphocyanide forms $C_8H_4O_2:NC_3H_6SCy$ [98°].

Ethylene-di-imide $(C_8H_4O_2.N)_2C_2H_4$. [232°]. Formed by heating potassium phthalimide with ethylene bromide at 200° (G.).

Butyl-imide $C_8H_4O_2:NC_4H_9$. [65°]. Formed by distilling cupric phthalyl-amido-hexoate (Reese, *A.* 242, 16). Tables (from dilute alcohol).

Isobutyl-imide $C_8H_4O_2:N.CH_2Pr$. [93°]. Formed from isobutyl bromide and potassium phthalimide (Neumann, *B.* 23, 999). Plates.

Isoamyl-imide $C_8H_4O_2:N.C_5H_{11}$. (308°). Solidifies when strongly cooled (N.).

Allyl-imide $C_8H_4O_2:NC_3H_5$. *Allyl-phthalimide.* [71°]. (295°). Tables. Yields a dichloride $C_8H_4O_2:NC_3H_5Cl_2$ [93°], and a dibromide [114°]. When nitrous acid is passed into its solution in cold benzene, and the product heated to 145°, there is formed $C_8H_4O_2:NC_3H_4NO_2$, crystallising in plates [178°] (Neumann, *B.* 23, 1000).

Acetonyl-imide $C_8H_4O_2:N.CH_2Ac$. [117°] Made by heating potassium phthalimide with chloro-acetone at 120° (Goedeckemeyer, *B.* 21, 2684). Plates and needles. Gives rise to an oxim [172°] and also to a phenyl-hydrazide $CH_3.C(N_2HPh).CH_2N:C_8H_4O_2$ [152°].

Desyl-imide $C_8H_4O_2:N.CHPhBz$. [158°]. Formed from phenyl bromo-benzyl ketone and potassium phthalimide (Neumann, *B.* 23, 994). Yellowish crystals, v. sl. sol. alcohol.

Phenyl-imide $C_6H_4<^{CO}_{CO}>NPh$. *Phthalanil.* [205°]. Formed by distilling phthalic acid (1 mol.) with aniline (1 mol.), and by heating phthalimide with aniline (Laurent; Doebner, *A.* 210, 267; Piutti, *B.* 16, 1322); Michael a. Palmer, *Am.* 9, 202). Needles (from alcohol), insol. water. Converted by heating with BzCl and $ZnCl_2$ into $C_8H_4O_2:N.C_6H_4Bz$ [183°] (Doebner, *A.* 210, 267). The *p*-chloro-, *p*-bromo-, *p*-iodo-, and *m*-nitro- phenyl-imides of phthalic acid melt at 195°, 204°, 228°, and 243° respectively (Gabriel, *B.* 11, 2260).

Benzyl-imide $C_8H_4O_2:NCH_2Ph$. [116°]. Formed from potassium-phthalimide and benzyl chloride (Gabriel, *B.* 20, 2227). Needles (from alcohol). The *o*- and *m*- nitro-benzylimides melt at 219° and 155° respectively.

o-Cyano-benzyl-imide $C_6H_4:C_2O_2:NCH_2.C_6H_4.CN$. [182°]. Prisms (from HOAc) (G.). The *p*- isomeride [184°] is converted into $CO_2H.C_6H_4.CO.NH.CH_2.C_6H_4.CO_2H$ [255°] by NaOHAq (Günther, *B.* 23, 1059).

Tolyl-imides $C_6H_4:C_2O_2:NC_6H_4Me$. The *o*-, *m*-, and *p*- compounds melt at 182°, 153°, and 204° respectively (Michael, *B.* 10, 579; Piutti, *A.* 227, 205; Fröhlich, *B.* 17, 2679; Kuhara, *Am.* 9, 52).

m-Methyl-benzyl-imide $C_6H_4:C_2O_2:N.CH_2C_6H_4Me$. [118°]. Formed by heating potassium phthalimide with $C_6H_4Me.CH_2Br$ at 200° (Brömme, *B.* 21, 2700). White needles, v. sol. alcohol. The compound $(C_6H_4:C_2O_2:N.CH_2)_2C_6H_4$ [237°] is formed by using [1:3] $C_6H_4(CH_2Br)_2$.

ψ-Cumyl-imide $C_{17}H_{15}NO_2$ *i.e.* $C_6H_4:C_2O_2:NC_6H_2Me_3$. [148°]. (above 360°). Formed by heating phthalic anhydride with ψ-cumidine (Fröhlich, *B.* 17, 1802). Trimetric crystals. Converted by ammonia into the compound $C_6H_4(CONH_2).CONHC_6H_2Me_3$ [218°], crystallising in needles, while methylamine and allyl-amine yield the corresponding compounds $C_6H_4(CONHMe).CONHC_6H_2Me_3$ [215°] and $C_6H_4(CONHC_3H_5).CONHC_6H_2Me_3$ [179°].

s-Tri-methyl-phenyl-imide $C_6H_4:C_2O_2:NC_6H_2Me_3$. *Phthalmesidil.* [171°]. Got by boiling mesidine with phthalic anhydride (Eisenberg, *B.* 15, 1017). Silky needles (from alcohol), insol. water. Yields, on nitration, the compounds $C_8H_4O_2:NC_6HMe_3(NO_2)$ [210°] and $C_8H_4O_2:NC_6Me_3(NO_2)_2$ [242°].

Isocymyl-imide $C_8H_4O_2:NC_{10}H_{13}$. [145°]. Formed by heating the anhydride with *m*-isocymidine (Kelbe a. Warth, *A.* 221, 169). Yields $C_8H_4O_2:NC_{10}H_{12}NO_2$ [167°] on nitration.

Naphthyl-imides $C_6H_4:C_2O_2:NC_{10}H_7$. The (α)- compound [166°] (P.); [182°] (M.) and its (β)- isomeride [216°] are got by heating the corresponding naphthylamines with phthalic anhydride (Piutti, *G.* 15, 479; Maschke, *C. C.* 1886, 824).

Tri-nitro-phenyl-imide $C_8H_4O_2:N.C_6H_2(NO_2)_3$. [259°]. From potassium phthalimide and picryl chloride (Schmidt, *B.* 22, 3257). Stair-like groups of crystals.

o-Oxy-phenyl-imide $C_6H_4:C_2O_2:NC_6H_4OH$. *Oxyphthalanil.* [220°]. Formed by heating phthalic anhydride with *o*-amido-phenol (Ladenburg, *B.* 9, 1528). Converted by sodium carbonate solution into $CO_2H.C_6H_4.CO.NH.C_6H_4OH$ [223°].

p-Oxy-phenyl-imide. [288°]. Got in like manner from *p*-amido-phenol (Piutti, *G.* 16, 252). Yields $C_6H_4:C_2O_2:N.C_6H_4OAc$ [239°] and $CO_2H.C_6H_4.CO.NH.C_6H_4OH$ [289°]. HNO_3 forms $C_6H_4:C_2O_2:NC_6H(NO_2)_2OH$ [210°], which yields an acetyl derivative [177°].

m-Nitro-phenacyl-imide $C_8H_4O_2:N.CH_2.CO.C_6H_4NO_2$. [204°]. Formed from ω-bromo-*m*-nitro-acetophenone and potassium phthalimide (Schmidt, *B.* 22, 3249). Pointed crystals (from HOAc).

Phenyl hydrazide $C_6H_4:C_2O_2:N_2HPh$. [178°]. Formed from phthalyl chloride and phenyl-hydrazine in ethereal solution (Pickel, *A.* 232, 233). Yellow needles, insol. water, sol. hot alcohol and chloroform.

Hydrides of phthalic acid. When reduced by sodium-amalgam in a solution kept acid by HOAc phthalic acid yields *trans* (1, 2)-dihydride. Neutral sodium phthalate reduced by sodium-amalgam without addition of acid yields the stable (4,5)-dihydride (Baeyer, *A.* 269, 154; cf. Graebe a. Born, *A.* 142, 330). Phthalic acid, suspended in water, is reduced by sodium-amalgam to a lactonic acid which yields a crystalline lactone [255°]; phthalide, and the (1,2)-dihydride are also formed. Both the (1,2)-dihydrides reduce aqueous $AgNO_3$ (*sic*) on warming, forming at once a black pp. Boiling aqueous cupric acetate gives off CO_2 and forms a white pp. which on addition of HOAc deposits Cu_2O. The liquid contains benzoic acid (Baeyer, *A.* 269, 151). None of the other dihydrides of phthalic acid are attacked by cupric acetate. Boiling *ammoniacal* $AgNO_3$ gives with: the (1,2)-dihydride a black pp.; the (4,5)- and (1,6)- dihydrides a brown pp.; the (3,6)- dihydride a white pp. not turning brown. The (1,2)- (1,6)- and (4,5)- dihydrides give benzoic acid and CO_2 when feebly oxidised. The (3,6)- dihydride gives phthalic acid (Baeyer, *A.* 269, 179). The hexahydrides are most stable, the tetra-hydrides next, and the dihydrides least stable (Baeyer, *A.* 269, 169). The *cis* anhydrides are more stable than the *trans* anhydrides. The *trans* acids are more stable than the *cis* acids. The anhydrides of the dihydrides are well crystallised, and yield the corresponding acids when boiled with water. The anhydrides are got by means of AcCl or Ac_2O. The (1,2)- dihydride will not stand AcCl. The (4,5)- dihydride needs long boiling with AcCl. Boiling Ac_2O often changes the *trans* to the *cis* variety. The anhydrides of the *cis* melt at lower temperatures than their *trans* isomerides (Baeyer, *A.* 269, 161).

In the following hydrides the two carboxyls are in the positions 1 and 2. The small numbers following Δ indicate the position of C atoms supposed doubly united to the adjacent C atoms.

Trans- $\Delta^{3,5}$ or (1,2)- *di-hydride.* $\begin{array}{l}\text{CH:CH.CH.CO}_2\text{H}\\ \text{CH:CH.CH.CO}_2\text{H}\end{array}$. [210°]. S. ·16 at 10°; 6 at 100°. Formed by reducing phthalic acid (20 g.) dissolved in NaOAc (32·8 g.) and water 200 c.c. at 0° by adding successive quantities of 3 p.c. sodium-amalgam (40 g.) and 50 p.c. acetic acid (6 c.c.), and finally adding H_2SO_4 (Baeyer, *A.* 269, 189). Prisms (from hot water). Not reduced by sodium-amalgam in the cold. Lead acetate gives a flocculent pp., sol. HOAc.

Reactions.—1. Boiling NaOHAq changes it entirely to the (4,5)-isomeride. Nine hours boiling with water does the same.—2. $KMnO_4$, hot ammoniacal $AgNO_3$, and aqueous $AgNO_3$ at 100° are at once reduced.—3. Aqueous *cupric acetate* forms a green pp., which gives off CO_2. On adding HOAc the liquid becomes clear and contains benzoic acid, Cu_2O being ppd.—4. Oxidised by boiling $CuSO_4$ to benzoic acid (Baeyer, *A.* 269, 191).—5. The acid takes up Br (4 at.) and the product is reduced by zinc-dust and HOAc to the original dihydride.—6. Combines with HCl, hence cannot be etherified by alcohol and HCl.—7. Combines with HBr (2 mols.) in aqueous solution at 100°. The product could not be crystallised, is reduced by sodium-amalgam to a hexahydride, while zinc and HOAc do not form an unsaturated acid.

Cis (1,2)-*dihydride.* [175°]. S. 1·8 at 10°. Does not accompany the *trans* form in the product of reduction of phthalic acid (Baeyer, *A.* 269, 192). The *trans* acid boiled with Ac_2O (but not AcCl) for 7 minutes is changed to the anhydride of the *cis* isomeride. The lead salt of the *cis* acid is insol. HOAc, while that of the *trans* acid is soluble therein. Large colourless many-faced prisms. Readily converted into anhydride by warming with Ac_2O. The anhydride [100°] crystallises from ether in colourless needles, and is re-converted into the acid by boiling water. The *cis* acid is converted into the (4,5)- dihydride by boiling NaOHAq, by 9 hours' boiling with water, and even (unlike the *trans* isomeride) by standing for 2 days with 15 p.c. NaOHAq. Reacts with silver and copper salts like the *trans* acid.

$\Delta^{2,6}$ or (4,5)-*Dihydride.* $\begin{array}{l}\text{CH}_2\text{.CH:C.CO}_2\text{H}\\ \text{CH}_2\text{.CH:C.CO}_2\text{H}\end{array}$ [215°]. S. ·3 at 25°; ·2 at 10°. Got by reducing phthalic acid (60 g.) with sodium-amalgam (1200 g.) (Baeyer, *A.* 269, 195; *cf.* Astié, *A.* 258, 187). Lustrous triclinic crystals.

Reactions.—1. Not affected by evaporating with boiling NaOHAq, but by long warming with very conc. aqueous or alcoholic KOH it is partially changed to the $\Delta^{2,4}$ or (1,6)- dihydride.—2. Reduced by sodium-amalgam in a current of CO_2 at 100° to Δ^2 or (1,4,5,6)- and *cis* and *trans* Δ^4 or (1,2,3,6)-tetrahydrides.—3. $KMnO_4$ oxidises it to oxalic and phthalic acids (no succinic acid).—4. Alkaline K_3FeCy_6 on boiling forms benzoic acid. Cold dilute H_2SO_4 and MnO_2 also form benzoic acid.—5. PCl_5 gives phthalic anhydride.—6. Br in the dark forms $C_8H_8Br_2O_4$ [185°].—7. With HBr (2 mols.) it combines forming crystalline di-bromo-phthalic acid hexahydride (Baeyer, *A.* 269, 198), which is reduced by sodium amalgam to phthalic acid *trans*-hexahydride. AcCl converts the acid into an anhydride [157°]. The silver salt boiled with water is reconverted into the (4,5)- dihydride. Alcoholic potash converts dibromophthalic acid hexahydride into the $\Delta^{2,4}$ or (1,6)- dihydride.

Methyl ether MeA′. (250°).

Anhydride [84°]. Got by boiling the (4,5) acid with AcCl (Baeyer, *A.* 269, 196). The product is evaporated over soda-lime and H_2SO_4 *in vacuo*, when the anhydride separates in large tables or prisms, sl. sol. ether, v. sol. chloroform. Hot water readily dissolves the anhydride, converting it into the parent acid. Na_2CO_3Aq forms an orange-red solution, which bleaches litmus as long as any anhydride is undissolved, the blue colour afterwards returning when all is dissolved. On adding H_2SO_4 to the solution a resin is ppd. Heating on the water-bath resinifies the anhydride, forming some phthalic anhydride.

$\Delta^{2,4}$ or (1,6)-*dihydride.* $\begin{array}{l}\text{CH CH}_2\text{.CH.CO}_2\text{H}\\ \text{CH.CH :C . CO}_2\text{H}\end{array}$ [180°]. Formed by boiling the di-hydro-dibromide of the (4,5)- dihydride of phthalic acid $\begin{array}{l}\text{CH}_2\text{.CHBr.CH.CO}_2\text{H}\\ \text{CH}_2\text{.CHBr.CH.CO}_2\text{H}\end{array}$ with a solution of KOH (1 pt.) in MeOH (2 pts.) for 1½ hours (Baeyer, *A.* 269, 199). Formed also in small quantity by heating the (4,5)- acid with conc. aqueous or alcoholic KOH or NaOH. Rosettes of prisms (from water). More soluble in water than the (4,5)- dihydride. Hot cupric acetate forms a white pp. which dissolves on cooling.

Reactions.—1. $KMnO_4$ and Na_2CO_3Aq form oxalic acid in the cold, and some phthalic acid. 2. Ammoniacal $AgNO_3$ forms a white pp. turning brown on warming.—3. Cold dilute H_2SO_4 and MnO_2 form benzoic acid and CO_2.—4. Boiling alkaline K_3FeCy_6 also forms benzoic acid.—5. Converted by Ac_2O in the cold into the anhydride which crystallises from chloroform in cubes [104°] and is reconverted into the acid by warm water. The anhydride dissolves in Na_2CO_3Aq and bleaches litmus meanwhile. The anhydride is converted by heat into the anhydride of the (3,6)- dihydride. — 6. *Sodium-amalgam* reduces it in the cold (difference from isomerides) to the *cis*-(1,2,3,6)- tetrahydride.—7. Combines with HBr (2 mols.) when heated at 100° with a solution of HBr in HOAc (Baeyer, *A.* 269, 200). The product [190°] crystallises from ether in plates, and is reduced by sodium-amalgam to the *trans* hexahydride.

$\Delta^{1,4}$ or (3,6)-*dihydride* $\begin{array}{l}\text{CH.CH}_2\text{.C.CO}_2\text{H}\\ \text{CH.CH}_2\text{.C.CO}_2\text{H}\end{array}$. [153°]. S. 1·7 at 6°. Formed by boiling the $\Delta^{2,4}$ or (1,6)- dihydride (1 pt.) with Ac_2O (2 pts.) for 6 minutes, and allowing the product to evaporate over soda-lime and H_2SO_4. The anhydride which separates is boiled with water (Baeyer, *A.* 269, 204). Large crystals with many facets. The Pb salt is sl. sol. HOAc. Cupric acetate gives a green pp., sl. sol. HOAc. The Ag salt is not reduced by boiling, even in presence of ammonia (unlike any of its isomerides).

Reactions.—1. When heated at 100° for a long time it is partially converted into anhydride. Evaporation of its aqueous solution also partially converts it into anhydride. The anhydride [185°] is also got by heating the acid with Ac_2O. It crystallises in plates.

Readily sublimes in feathery plates. Does not bleach litmus.—2. *Sodium-amalgam* does not reduce it even when gently warmed (Baeyer, *A.* 269, 205).—3. Dilute H_2SO_4 and MnO_2 oxidise it to phthalic acid. Boiling alkaline K_3FeCy_6 also forms phthalic acid.—4. $KMnO_4$ is at once decolourised.—5. Boiling (10 p.c.) NaOHAq forms (4,5) and (1,6)- isomerides.

Δ^1 or (3,4,5,6)-*Tetrahydride* $\begin{array}{l}CH_2.CH_2.C.CO_2H\\ CH_2.CH_2.C.CO_2H\end{array}$. [120°]. Formed by dissolving its anhydride in boiling water (Baeyer a. Astié, *A.* 258, 203; 269, 176). Got also by distilling the tetrahydride of pyromellitic acid (Baeyer, *A.* 166, 346). Monoclinic leaflets (containing aq). When heated at 100° for some time it melts, forming the anhydride. $KMnO_4$ oxidises it to adipic acid. Boiling conc. KOHAq changes it to the Δ^2 acid. Oxidised by Br and alkalis to di-oxy-phthalic acid hexahydride (tartrophthalic acid).—BaA″ aq: crystalline pp.

Methyl ether Me_2A''. Combines with Br, forming two dibromides [84°] and [124°].

Anhydride $C_8H_8O_3$. [74°]. Formed by heating the Δ^2 acid or its anhydride at 215° for some time. Plates (from ether), v. sol. ether.

Δ^2 or (1,4,5,6)-*Tetrahydride* $\begin{array}{l}CH_2.CH_2.CH.CO_2H\\ CH_2.CH:C\ .\ CO_2H\end{array}$. [215°]. S. ·88 at 10° H.C.p. 881,600. H.F. 215,400 (Stohmann, *J. pr.* [2] 43, 540). Got by reducing a boiling solution of sodium phthalate with sodium-amalgam (Baeyer, *A.* 258, 175). Formed also, together with the *trans* Δ^4 isomeride, by reducing the (4,5)-dihydride in the same way. Prisms (from water). Bromine vapour yields a dibromide [225°]. MeOH and HCl form an oily methyl ether, which yields a crystalline dibromide [74°]. $KMnO_4$ oxidises it to oxalic and succinic acids.

Anhydride $C_8H_8O_3$. [79°]. Formed from the acid and AcCl. Prisms. Changed by heat into the anhydride of the Δ^1 acid.

Trans-Δ^4 or (1,2,3,6)-*Tetrahydride* $\begin{array}{l}CH.CH_2.CH.CO_2H\\ CH.CH_2.CH.CO_2H\end{array}$. [218°]. S. ·145 at 6°. Formed, together with the (1,4,5,6)-tetrahydride, by reducing the (4,5)-dihydride in boiling solution by sodium-amalgam (Baeyer, *A.* 258, 210; 269, 161). Leaflets (from water). Decolourises $KMnO_4$ at once. Yields a methyl ether Me_2A'' [40°], which forms a dibromide [117°]. Anhydride $C_8H_8O_3$. [140°]. Got from the acid and AcCl. Needles (from ether). Changed by heat into the *cis*- isomeride.

Cis-Δ^4 or (1,2,3,6)-*Tetrahydride* [174°]. S. ·9 at 6°. Formed by adding sodium-amalgam at 0° to a solution of the Na salt of the (1,6)-dihydride in a current of CO_2 (Baeyer, *A.* 269, 202). Formed also by boiling the *trans* Δ^4 tetrahydride with Ac_2O for 15 minutes. Large prisms. Boiling Ac_2O forms the anhydride, which crystallises from ether in tables [59°].

Trans- (or fumaroid) *hexahydride* $C_6H_{10}(CO_2H)_2$. [221°]. S. ·23 at 20°. Formed by reducing the hydrobromides of the di- and tetra- hydrides with sodium-amalgam or with zinc-dust and HOAc (Baeyer, *A.* 166, 350; 258, 214; 269, 161; *cf.* Mizerski, *B.* 4, 558). By reducing the (3,4,5,6)-tetrahydride in a hot solution a mixture of *trans*- and *cis*- hexahydrides is obtained. Leaflets (from water). May be distilled unchanged if quickly heated, but yields the *cis*- anhydride when slowly heated. Not oxidised by cold aqueous $KMnO_4$. Yields a dimethyl ether [83°], m. sol. ligroïn.—PbA″ aq: plates.

Anhydride. [140°]. Formed from the acid and AcCl. Long needles (from ether). Changes when heated into the *cis*-isomeride.

Cis- (or maleoid) *hexahydride.* [c. 192°]. Got from its anhydride, which is formed by heating the anhydride of the *trans*- isomeride at 220° for eight hours. Short four-sided prisms, more soluble than the trans- isomeride. Not attacked by cold aqueous $KMnO_4$. Conc. HClAq at 180° changes it to the *trans*- variety. The Ba and Zn salts are less sol. hot than cold water.

Anhydride. [32°].

Isophthalic acid [1:3] $C_6H_4(CO_2H)_2$. [c. 300°]. S. ·013 at 25°; ·22 at 100°. H.C.v. 769,100. H.C.p. 768,800. H.F. 190,200 (Stohmann, *J. pr.* [2] 40, 138).

Formation.—1. By oxidising *m*-xylene with $K_2Cr_2O_7$ and H_2SO_4 (Fittig a. Velguth, *Z.* [2] 3, 526; *A.* 148, 11; 153, 268).—2. By fusing sodium formate with potassium *m*-sulpho-benzoate (V. Meyer, *A.* 156, 265; 159, 1).—3. The ether is formed by the action of $ClCO_2Et$ and sodium-amalgam on *m*-di-bromo-benzene (Wurster, *A.* 176, 149).—4. By fusing potassium formate with potassium benzoate (Richter, *B.* 6, 876), *m*-bromo-benzoate (Ador a. Meyer, *A.* 159, 16), or di-sulpho-benzoate (Barth a. Senhofer, *A.* 159, 228).—5. By oxidation of *m*-toluic acid (Weith a. Landolt, *B.* 8, 715).—6. By saponification of its nitrile.—7. By heating the hydrides of prehnitic and pyromellitic acids with H_2SO_4 (Baeyer, *A.* 166, 334; *Suppl.* 7, 4).—8. By strongly heating NaOBz (Conrad, *B.* 6, 1395).—9. By oxidation of colophony with dilute nitric acid (Schreder, *A.* 172, 93).—10. By the action of a hot aqueous solution of cuprous potassium cyanide upon *m*-diazo-benzoic chloride, and saponification of the resulting nitrile (Sandmeyer, *B.* 18, 1498).

Preparation.—*m*-Xylene is converted, by heating with bromine at 125°, into $C_6H_4(CH_2Br)_2$, which is boiled with alcoholic potash, and the resulting $C_6H_4(CH_2OEt)_2$ oxidised with chromic acid mixture (Kipping, *B.* 21, 46).

Properties.—Long slender needles (from water), m. sol. alcohol. May be sublimed.

Salts.—K_2A''.—BaA″ 6aq. Triclinic crystals (by spontaneous evaporation) (Lossen, *A.* 266, 30). V. sol. water.—BaA″ 4aq? Needles (by cooling hot saturated solutions).—CaA″ 2½aq: needles.—Ag_2A'': amorphous pp.

Methyl ether Me_2A''. [65°]. Needles (from dilute alcohol). H.F. 173,300 (Stohmann, *J. pr.* [2] 40, 353).

Di-ethyl ether Et_2A''. [0°]. (285°).

Di-phenyl ether Ph_2A''. [120°]. Got by boiling the chloride with phenol. Long needles.

Chloride $C_6H_4(COCl)_2$. [41°]. (276°). Formed by heating the acid with PCl_5 at 200° (Schreder, *B.* 7 708; Münchmeyer, *B.* 19, 1849).

Amide $C_6H_4(CO.NH_2)_2$. [265°] (B. Beyer, *J. pr.* [2] 22, 351); [above 270°] (Luckenbach, *B.* 17, 1431). Got from the chloride and NH_3. Plates, sl. sol. water and alcohol.

Nitrile $C_6H_4Cy_2$. [158°]. Formed by distilling potassium cyanide with potassium benzene *m*-disulphonate (Barth a. Senhofer, *A.* 174, 236; Meyer a. Michler, *B.* 8, 672; Nölting, *B.* 8, 1112; Luckenbach, *B.* 17, 1428), or with potassium *m*-chloro- or bromo- benzene sulphonate (Meyer a. Stüber, *A.* 165, 165; Limpricht, *A.* 180, 92). Formed also by heating the oxim of isophthalic aldehyde $C_6H_4(CH{:}NOH)_2$ with excess of AcCl at 100° for a long time (Münchmeyer, *B.* 20, 508), by the dry distillation of calcium *m*-cyano-benzoate (Brömme, *B.* 20, 521), and by boiling an alcoholic solution of $C_6H_4(CS.NH_2)_2$ with an aqueous solution of lead acetate (Luckenbach). Small needles (from alcohol), insol. water, m. sol. ether. Converted by alcohol and dry HCl into phthalimido-ethyl ether $C_6H_4(C(NH).OEt)_2$ [66°]. MeOH and HCl yield $C_6H_4(C(NH).OMe)_2$ [c. 62°]; while mercaptan and HCl form $C_6H_4(C(NH).SEt)_2$, which, like the two preceding bodies, forms a crystalline hydrochloride (Luckenbach).

Semi-nitrile v. *m*-CYANO-BENZOIC ACID.

Tetrahydride of Isophthalic acid $C_6H_8(CO_2H)_2$. [199°]. Formed by reduction of isophthalic acid by boiling its alkaline solution with sodium-amalgam (Baeyer, *B.* 19, 1806). Needles, v. sol. hot water.—Ag_2A'': white pp.

Methyl ether Me_2A''. Oil.

Isomeride *v.* TEREPHTHALIC ACID.

References.—AMIDO-, BROMO-, BROMO-NITRO-, CHLORO-, IODO-, NITRO-, OXY-, and OXY-AMIDO-PHTHALIC ACIDS.

Homo-phthalic acid *v.* CARBOXY-PHENYL-ACETIC ACID.

Diphthalic acid *v.* DIPHTHALYLIC ACID.

PHTHALIC ALCOHOL *v.* DI-OXY-XYLENE.

PHTHALIC ALDEHYDE $C_8H_6O_2$ *i.e.* $C_6H_4(CHO)_2$ [1:2]. Mol. w. 134. [52°]. Formed by boiling $C_6H_4(CHCl_2)_2$ (1 mol.) with NaOHAq (4 mols.) (Colson a. Gautier, *Bl.* [2] 45, 509; *A. Ch.* [6] 11, 29). Formed also by oxidising $C_6H_4(CH_2.OH)_2$ (Hjelt, *B.* 19, 411). Solid, v. sl. sol. water. Coloured blue by NH_3Aq. Slowly oxidised by air.

Oxim $C_6H_4(CH{:}NOH)_2$. [215°]. Small needles (Münchmeyer, *B.* 20, 509).

Isophthalic aldehyde $C_6H_4(CHO)_2$ [1:3]. [90°]. Formed by boiling $C_6H_4(CHCl_2)_2$ [1:3] with water (Colson a. Gautier, *Bl.* [2] 45, 509; V. Meyer, *B.* 20, 2005). Needles. Reduces silver solution with difficulty. Gives a violet-red tint with rosaniline reduced by SO_2. Oxidised by $KMnO_4$ to isophthalic acid.

Oxim $C_6H_4(CH{:}NOH)_2$. [212°] (Münchmeyer); [180°] (Meyer). Plates (from hot alcohol). Converted by AcCl at 100° into $C_6H_4Cy_2$. Yields the ethers $C_6H_4(CH{:}NOMe)_2$ [77°] and $C_6H_4(CH{:}NOEt)_2$ [165°].

Reference.—OXY-ISOPHTHALIC ALDEHYDE.

Isomerides.—TEREPHTHALIC ALDEHYDE and PHTHALIDE.

PHTHALIC ALDEHYDE ACID *v.* ALDEHYDO-BENZOIC ACID and PHTHALALDEHYDIC ACID.

PHTHALIDE $C_8H_6O_2$ *i.e.* $C_6H_4<\genfrac{}{}{0pt}{}{CH_2}{CO}>O$. *Lactone of ω-Oxy-o-toluic acid.* [73°]. (290° i.V.).

Formation.—1. By reducing phthalyl chloride with zinc and HClAq (Kolbe a. Wischin, *C. J.* 19, 339), or with Mg and HOAc (Baeyer, *Z.* [2] 5, 399; 10, 123, 1445; 11, 637).—2. Occurs among the products of reduction of phthalic anhydride by zinc-dust and HOAc (Wislicenus, *B.* 17, 2178).—3. By passing bromine-vapour over *o*-toluic acid at 140° (Hjelt, *B.* 19, 412).

Preparation.—Phthalimide (1 pt.) is reduced to phthalidene by means of tin ($1\frac{3}{4}$ pts.) and HCl. The tin is ppd. by zinc, and sodium nitrate added to the filtrate. The yellow pp. of the nitrosamine of phthalidine is filtered off, washed, and heated with dilute NaOH. The phthalide is ppd. by HCl and distilled. Yield on the phthalic anhydride – 70 p.c. of the theoretical (Graebe, *B.* 17, 2599).

Properties.—Needles (from hot water), sl. sol. cold water, v. sol. alcohol and ether. Does not combine with $NaHSO_3$ (Hessert, *B.* 11, 238), or reduce ammoniacal $AgNO_3$. Does not react with hydroxylamine.

Reactions.—1. Oxidised by alkaline $KMnO_4$ to phthalic acid.—2. *Alkalis* and *alkaline carbonates* form ω-oxy-*o*-toluic acid, *v.* vol. iii. p. 781.—3. *Sodium-amalgam* forms hydrophthalide $C_8H_8O_2$, a viscid mass, v. sol. alcohol and ether, and also 'phthalylpinacone' $C_{16}H_{18}O_4$ [197°].—4. *Ammonia* on heating forms phthalimidine.—5. *Aniline* at 210° forms phenyl-phthalimidine.—6. *Phthalic anhydride* on heating forms diphthalyl.—7. KCy at 185° forms $C_6H_4(CH_2.CN).CO_2H$ [116°], which forms CaA'_2 2aq, and yields carboxy-phenyl-acetic acid on saponification (Wislicenus, *B.* 18, 172; 233, 112). KCy at 200° yields $C_{18}H_{11}N_2O_3$ (?) [240°–245°].—8. Boiling HIAq forms *o*-toluic acid. 9. Br at 140° forms *exo*-bromo-phthalide. Cl at 160° yields phthalyl chloride (Racine, *A.* 239, 79).—10. NaOEt acting on an ethereal solution of oxalic ether and phthalide forms an ether $C_{12}H_{10}O_5$ [122°] crystallising from alcohol in needles, and forming with phenyl-hydrazine the compound $C_{18}H_{16}N_2O_4$ [159°] (Wislicenus, *B.* 20, 2062; *A.* 246, 342).

Phenyl-hydrazine compound $C_{14}H_{14}N_2O_2$ *i.e.* $CH_2(OH).C_6H_4.CO.N_2H_2Ph$. [174°]. Readily formed by warming phthalide with phenyl-hydrazine for a few hours (Meyer a. Münchmeyer, *B.* 19, 1707, 2132; Wislicenus, *B.* 20, 401). Sol. hot water and alcohol, sl. sol. ether. Silvery needles. Partially resolved into the parent substances by fusion. Very unstable towards acids and alkalis. H_2SO_4 forms a colourless solution, turned reddish-violet by $FeCl_3$.

References.—AMIDO-, BROMO-, CHLORO-, NITRO-, and OXY-PHTHALIDE.

PHTHALIDE CARBOXYLIC ACID *v.* OXY-CARBOXYL-PHENYL-ACETIC ACID.

PHTHALIDE SULPHONIC ACID $SO_3H.C_6H_4<\genfrac{}{}{0pt}{}{CH_2}{CO}>O$. Formed by warming phthalide with fuming H_2SO_4 (20 p.c. SO_3 extra) (Hoenig, *B.* 18, 3453). Needles, v. sol. alcohol, insol. ether.—BaA'_2.—CuA'_2 2aq: light-blue prisms.

PHTHALIDINE is PHTHALIMIDINE.

PHTHALIMIDINE C_8H_7NO *i.e.* $C_6H_4<\genfrac{}{}{0pt}{}{CH_2}{CO}>NH$. [150°]. (337°) at 730 mm. Formed by reducing phthalimide with tin and HCl, and by heating phthalide in a current of NH_3 (Graebe, *B.* 17, 2598; 18, 1408; *A.* 247, 290; Barbier, *C. R.* 107, 918). Needles or prisms, sl. sol. cold water, v. e. sol. alcohol and ether. Not volatile with steam. Oxidised by

$KMnO_4$ to phthalimide. Bromine forms $C_{16}H_9N_2O_2Br_3$ [150°]. Distillation over zinc-dust forms phenyl-isoquinoline. Yields a nitro-derivative

$C_6H_4{<}\begin{matrix}CH(NO_2)\\CO\end{matrix}{>}NH$

[210°], converted by oxidation into phthalide. Yields also a di-nitro- derivative [195°].

Salts. — B'HCl. [150°]. Thin white needles, v. sol. water.—$B'_2H_2PtCl_6$.—B'_2HAuCl_4. [176°].—$B'C_6H_2(NO_2)_3OH$. [140°].—C_8H_6AgNO.

Acetyl derivative C_8H_6AcNO. [151°]. Needles (from dilute HOAc).

Nitrosamine $C_8H_6(NO)NO$. [156°]. Yellow needles (from water or alcohol). Converted by NaOHAq into ω-oxy-*o*-toluic acid, and by NaSH into thio-phthalide C_8H_6OS [60°].

Reference.—DI-CHLORO-PHTHALIMIDINE.

pseudo-**Phthalimidine** C_8H_7NO probably

$C_6H_4{<}\begin{matrix}CH_2\\CO\end{matrix}{>}NH$.

This compound is formed, as hydrochloride, by heating ω-chloro-*o*-toluylamide $C_6H_4(CH_2Cl).CO.NH_2$ to 150°-160°. The picrate $B'C_6H_2(NO_2)_3OH$ forms a crystalline yellow pp.; the salt $B'_2H_2Cl_2PtCl_4$ 2aq forms flat orange-yellow needles (Gabriel, *B.* 20, 2234).

ISO-PHTHALIMIDO-ETHYL ETHER $C_6H_4(C(NH).OEt)_2$ [1:3]. [66°]. The hydrochloride is got by passing dry HCl into a mixture of isophthalic nitrile (1 mol.) and absolute alcohol (2 mols.) dissolved in benzene (Luckenbach, *B.* 17, 1431). The free base crystallises in small needles, v. sol. alcohol and ether. It decomposes on heating into alcohol and isophthalic nitrile.—$B''H_2Cl_2$. [270°]. Crystalline.

PHTHALIMIDYL-BENZYL *v.* BENZYLIDENE-PHTHALIMIDINE.

PHTHALIMIDYL PROPIONIC ACID $C_{11}H_9NO_3$ *i.e.*

$C_6H_4{<}\begin{matrix}C{:}CH.CH_2.CO_2H\\CO.NH\end{matrix}$.

[225°]. Formed by dissolving the dilactone of phenyl ethyl ketone dicarboxylic acid in NH_3Aq (Roser, *B.* 18, 3119). Long yellowish needles, v. sol. hot alcohol.—BaA'_2.—CaA'_2 aq.—AgA'.

Lactone $C_{11}H_9NO_3$. [c. 205°]. Formed by evaporating the dilactone mentioned above with conc. NH_3Aq on the water-bath. Small tables, v. sol. alcohol, sl. sol. cold water. Reconverted by boiling HClAq into the dilactone. Dissolves easily in cold aqueous alkalis, forming salts of a dibasic acid $C_{11}H_{11}NO_4$.

PHTHALONITRILE *v. Nitrile* of PHTHALIC ACID.

PHTHALOPHENONE *v.* DI-PHENYL-PHTHALIDE.

o-**Phthalophenone** $C_6H_4Bz_2$ [1:2]. [146°]. Got by oxidising *o*-di-benzyl-benzene (Zincke, *B.* 9, 31). Tables (from alcohol).

Isophthalophenone $C_6H_4Bz_2$ [1:3]. *Phenylene di-phenyl diketone.* [100°]. Formed by the action of benzene and $AlCl_3$ on isophthalyl chloride (Ador, *B.* 13, 320). Plates (from alcohol). Yields two dinitro- derivatives [200°] and [100°]?

Mono-oxim $C_6H_5.C(NOH).C_6H_4Bz$. [201°] (Nölting, *B.* 19, 146). Nodules, v. sol. alcohol.

Di-oxim $(C_6H_5.C(NOH))_2C_6H_4$. [70°-75°] (Münchmeyer, *B.* 19, 1849). Small crystals.

p-**Phthalophenone** $C_6H_4Bz_2$ [1:4]. *Terephthalophenone. (a)-Di-benzoyl-benzene.* [160°]. Formed by oxidising *p*-di-benzyl-benzene with CrO_3 and HOAc (Zincke, *B.* 9, 31; Wehnen, *B.* 9, 309). Got also from terephthalyl chloride, benzene, and $AlCl_3$ (N.). Plates (from benzene). PCl_5 yields $C_{20}H_{14}Cl_4$ [92°]. Sodium-amalgam forms di-oxy-di-benzyl-benzene [171°].

Mono-oxim. [213°]. Nodules.

Di-oxim. [235°]. Crystals.

PHTHALOXYL-AMIDO-ACETIC ACID $C_{10}H_9NO_5$ *i.e.* $CO_2H.C_6H_4.CO.NH.CH_2.CO_2H$. *Glycocoll-phthaloylic acid.* [106°]. Formed by the action of alkalis on phthalyl-amido-acetic acid (Reese, *A.* 242, 6; Gabriel a. Kroseberg, *B.* 22, 426). Six-sided plates (containing aq).—Na_2A''. K_2A'': hygroscopic needles.—BaA''.—Ag_2A'': plates, sl. sol. hot water.

PHTHALOXYL-AMIDO-BENZOIC ACID $CO_2H.C_6H_4.CO.NH.C_6H_4.CO_2H$. [277°]. Formed by oxidation of the *p*-tolylimide of phthalic acid with $KMnO_4$ (Michael, *B.* 10, 576).

PHTHALOXYL-AMIDO-HEXOIC ACID $CO_2H.C_6H_4.CO.NH.C_4H_7Me.CO_2H$. Occurs in two varieties, the active [132°] and inactive [1[illegible]3°], which are got by boiling the corresponding phthalyl-amido-hexoic acids with NaOHAq (Reese, *A.* 242, 20). Both acids are decomposed by boiling water into leucine and phthalic acid.

PHTHALURIC ACID *v. Uramic acid* of PHTHALIC ACID.

DIPHTHALYL $C_{16}H_8O_4$ *i.e.*

$C_6H_4{<}\begin{matrix}C{:}C\\CO.O\quad O.CO\end{matrix}{>}C_6H_4$.

[335°].

Formation. 1. By heating phthalyl chloride with reduced silver at 150° (Ador, *A.* 164, 229). 2. By fusing phthalic anhydride with zinc-dust; and, together with other products, by reducing phthalic anhydride with zinc-dust and HOAc (Wislicenus, *B.* 17, 2178).—3. By heating phthalide with NaOAc and phthalic anhydride or thio-phthalic anhydride (Graebe a. Guye, *B.* 17, 2851; *A.* 228, 126; 233, 241).—4. By boiling phthalaldehydic ether with alcoholic KCN (Goldschmidt a. Egger, *M.* 12, 60).

Properties.—Needles, insol. water, v. sl. sol. alcohol and ether. May be sublimed in a current of CO_2. Combines with Br forming $C_{16}H_8Br_2O_4$ [c. 225]. PCl_5 at 160° forms the chloride $C_{16}H_8Cl_2O_4$ [245°]. Bromine and water at 100° form bromo-diphthalyl, which crystallises from benzene. Alkalis form diphthalyl-lactonic acid.

Hydride $C_{16}H_{10}O_4$ *i.e.*

$C_6H_4{<}\begin{matrix}CH.CH\\CO.O\quad O.CO\end{matrix}{>}C_6H_4$

[229°] (W.); [250°] (Hasselbach, *A.* 243, 249), a product of the action of zinc-dust and HOAc on phthalic anhydride (Wislicenus). Needles (from alcohol), v. sol. HOAc. Potash forms di-oxy-di-phenyl-ethane dicarboxylic acid.

References.—TETRA-CHLORO-, NITRO-, and OXY- DIPHTHALYL.

PHTHALYL-ACETIC ACID $C_{10}H_6O_4$ *i.e.*

$C_6H_4{<}\begin{matrix}C{:}CH.CO_2H\\CO.O\end{matrix}$.

[c. 246°] (G.); [above 260°] (Roser, *B.* 17, 2620). Formed by boiling phthalic anhydride (10 pts.) with Ac_2O (20 pts.) and NaOAc (2 pts.) (Michael a. Gabriel, *B.* 10, 391, 1551, 2199). Formed also by dissolving acetophenone oω-dicarboxylic acid in H_2SO_4 (Gabriel, *B.* 17, 2521). Needles (from nitrobenzene), insol. water, v. sl. sol. hot alcohol.

Reactions.—1. Aqueous NaOH (1 mol.) forms a solution of its Na salt, but *excess of alkali* converts it into acetophenone *oω*-dicarboxylic acid. 2. *Distillation in vacuo* splits it up into CO_2 and methylene-phthalide.—3. *Bromine* in HOAc gives $CBr_2.CO.C_6H_4.CO_2H$ [160°]. Dry Br gives $C_8H_4O_2:CBr.CO_2H$ [c. 235°].—4. *Chlorine* acting on the HOAc solution forms $CCl_3.CO.C_6H_4.CO_2H$ [144°].—5. H_2SO_4 at 100° forms tri-benzoylene-benzene (*v.* vol. i. p. 485).—6. *Ammonia* gives rise to phthalimidyl-acetic acid $C_{10}H_7NO_3$ *i.e.* $C_6H_4<\begin{matrix}C:CH.CO_2H\\CO.NH\end{matrix}$ (?) which crystallises from water in needles [c. 200°] and yields CaA'_2aq, $BaA'_2 4aq$, and AgA' (Roser, *B.* 17, 2623; Gabriel, *B.* 18, 2451).—7. $NMeH_2Aq$ at 0° forms $NHMe.CO.C_6H_4.CO.CH_2.CO_2H$ [145°], which is converted by concentrated H_2SO_4 into $C_6H_4<\begin{matrix}C:CH.CO_2H\\CO.NMe\end{matrix}$ [c. 212°], crystallising from alcohol in silky needles, split up by heat into CO_2 and  $C_6H_4<\begin{matrix}C:CH_2\\CO{\cdot}NMe\end{matrix}$, a crystalline mass which is converted by bromine-water into $C_{10}H_{10}BrNO_2$ [126°] (Gabriel, *B.* 18, 2453).—8. Aqueous *ethylamine* forms $C_{23}H_{24}O_5N_2$ crystallising from ether in needles [129°], converted by cold H_2SO_4 into  $C_6H_4<\begin{matrix}C:CH.CO_2H\\CO{\cdot}NEt\end{matrix}$ [180°] and by heat into liquid  $C_6H_4<\begin{matrix}C:CH_2\\CO{\cdot}NEt\end{matrix}$ (Mertens, *B.* 19, 2368).—9. *Propylamine* forms, in the cold, $C_{25}H_{28}N_2O_5$ [103°], crystallising in prisms (M.).—10. *Aniline* at 100° forms $C_{15}H_{13}NO_2$ [192°], crystallising from benzene in cubes, converted by cold H_2SO_4 into $C_{15}H_{11}NO$ [265°] and by heating at 204°–230° into the isomeric  $C_6H_4<\begin{matrix}C:CH_2\\CO{\cdot}NPh\end{matrix}$ [100°] (Mertens, *B.* 19, 2371).—11. *Secondary* and *tertiary amines* have no action.—12. *Sodium-amalgam* forms the lactone of oxy-carboxy-phenyl-propionic acid (*q.v.*).

Salt.—$AgC_{10}H_5O_4$: amorphous pp.

PHTHALYL-DIACETIC ACID

$C_6H_4<\begin{matrix}C(CH_2.CO_2H)_2.\\CO.O\end{matrix}$ [158°]. Formed by saponifying phthalyl-di-malonic ether with KOHAq (Wislicenus, *A.* 242, 80). Prisms.—$BaA''2aq$: prisms, v. sol. water.—Ag_2A''.

PHTHALYL-ACETOACETIC ETHER $C_{11}H_{12}O_5$ *i.e.*  $C_6H_4<\begin{matrix}C:CAc.CO_2Et.\\CO.O\end{matrix}$ [124°]. Formed from sodium acetoacetic ether and phthalyl chloride (Fischer a. Koch, *B.* 16, 651; Bülow, *A.* 236, 185). Prisms (from alcohol). Decomposed by H_2SO_4 at 65° into HOAc and phthalyl-acetic acid. Alcoholic KOH forms deliquescent crystalline $K_2C_{14}H_{14}O_7$. Phenyl-hydrazine acetate forms $C_{20}H_{18}N_2O_4$ [238°], which is reduced by zinc-dust and HOAc to carboxy-benzyl-acetoacetic ether [92°].

PHTHALYL ALCOHOL *v.* DI-ω-OXY-*o*-XYLENE.

PHTHALYL-AMIDO-ACETIC ACID $C_{10}H_7NO_4$ *i.e.* $C_8H_4:C_2O_2:N.CH_2.CO_2H$. *Phthalyl glycocoll.* [192°]. Formed by heating phthalic anhydride (2 pts.) with glycocoll (1 pt.) (Drechsel, *J. pr.* [2] 27, 418; Reese, *A.* 242, 1). Crystals (from water), decomposed by boiling HClAq into phthalic acid and glycocoll. Cold NaOHAq forms phthaloxy-amido-acetic acid (*q. v.*).—NaA'aq.—NH_4A'. [206°].—$CaA'_2 2aq$.—$CuA'_2 3aq$.—AgA'.—$Pt(N_2H_6A')_2$. Colourless prisms; got by evaporating a solution of the acid with oxide of plato-diammonium.

Ethyl ether EtA'. [105°] (R.); [113°] (G.). (above 300°). Formed from Ag_2A'' and EtI (R.), and also by heating potassium phthalimide with $CH_2Cl.CO_2Et$ (Goedeckemeyer, *B.* 21, 2688; Gabriel, *B.* 22, 426). Needles, v. sol. benzene.

PHTHALYL-*p*-AMIDO-BENZENE SULPHONIC ACID $C_6H_4:C_2O_2:N.C_6H_4.SO_3H$. The Na salt, got by heating phthalic anhydride with sodium *p*-amido benzene sulphonic acid at 250°, crystallises from water in silky needles (Pellizzari, *A.* 248, 153; *G.* 18, 314). It is converted by boiling ammonia into phthalimide and sodium *p*-amido-benzene sulphonate. The Ba and NH_4 salts are also crystalline.

PHTHALYL-*o*-AMIDO-BENZOIC ACID $C_6H_4:C_2O_2:NC_6H_4.CO_2H$. [217°]. Formed by heating anthranilic acid with phthalic anhydride (Gabriel, *B.* 11, 2261). Prisms, sol. HOAc.

Phthalyl-*m*-amido-benzoic acid. [276°] (G.); [282°] (P.). Formed from phthalic anhydride and *m*-amido-benzoic acid, and also by saponifying its ether [152°], which is formed by heating phthalic ether with *m*-amido-benzoic acid (Pellizzari, *B.* 18, 216; *A.* 232, 147). Needles. The amide is described in vol. i. p. 158.

Anilide. [209°]. Prisms (Piutti, *B.* 16, 1322).

PHTHALYL-AMIDO-ETHANE SULPHONIC ACID $C_8H_4O_2:N.C_2H_4.SO_3H$. **Salt.**—$KA'\frac{1}{2}aq$. Formed by heating potassium amido-ethane sulphonate with phthalic anhydride (Pellizzari, *G.* 18, 324). Monoclinic crystals; *a:b:c* = 7·908:1:2·594; β = 60° 42'. Decomposed by alcoholic NH_3 into phthalimide and taurine.

PHTHALYL-AMIDO-HEXOIC ACID $C_{14}H_{15}NO_4$ *i.e.* $C_8H_4O_2:N.CH(C_4H_9).CO_2H$. [116°]. $[\alpha]_D = -21{\cdot}87°$ in a 5 p.c. alcoholic solution at 22°. Formed by fusing leucine with phthalic anhydride (Reese, *A.* 242, 9). Needles, v. sl. sol. hot water. Lævorotatory. Converted by distillation into an inactive variety [142°], which yields $PtN_2H_6A'_2 3\frac{1}{2}aq$. Conc. HClAq at 150° forms leucine and phthalic acid. NaOHAq forms phthaloxy-amido-hexoic acid (*q. v.*).—NaA'.—NH_4A'. [160°–165°].—$PtN_2H_6A'_2 3aq$.

PHTHALYL-AMIDO-NAPHTHALENE SULPHONIC ACID $C_8H_4:C_2O_2:N.C_{10}H_6.SO_3H$. The salt KA'3aq is got by heating sodium (α)-naphthylamine sulphonate with phthalic anhydride (Pellizzari a. Matteuci, *G.* 18, 321). It crystallises in needles, sol. water.

PHTHALYL-γ-AMIDO-*n*-PROPYL-MALONIC ETHER $C_6H_4:C_2O_2:N.CH_2.CH_2.CH_2.CH(CO_2Et)_2$. [48°]. Formed by the action of sodium malonic ether on the γ-bromo-propyl-imide of phthalic acid (Gabriel, *B.* 23, 1767). Monoclinic plates (from ligroïn); *a:b:c* = 3·260:1:1·644; β = 81° 4'. Converted into δ-amido-valeric acid by heating with HClAq at 190°.

Phthalyl-amido-di-propyl-malonic ether $C_8H_4O_2:N.CH_2.CH_2.CH_2.CPr(CO_2Et)_2$. [57°]. Formed in like manner from propyl-malonic ether (Aschan, *B.* 23, 3698). Prisms, insol. water, v. sol. alcohol and ether.

DI-PHTHALYL-DI-AMIDO-QUINONE $C_{22}H_{10}N_2O_6$ *i.e.* $C_6H_2O_2(N:C_2O_2:C_6H_4)_2$ [1:2:4:6]. [277°]. Prepared by heating tri-amido-phenol hydrochloride with phthalic anhydride, dissolving the resulting $C_6H_2(OH)(N{:}C_2O_2{:}C_6H_4)_2$ [above 300°] in potash, and treating the product $C_6H_2(OH)(NH.CO.C_6H_4.CO_2H)_2$ [above 300°] with nitric acid (S.G. 1·48) (Piutti, *G.* 16, 254). Yellow needles (from HNO_3). Forms a compound [174°] with phenyl-hydrazine. H_2S passed into its solution in dilute HOAc forms crystalline $C_6H_2(OH)_2(N{:}C_2O_2{:}C_6H_4)_2$, not melted at 310°.

PHTHALYL-AMIDO-SUCCINIC ACID $C_{12}H_9NO_6$ *i.e.* $C_8H_4O_2{:}N.CH(CO_2H).CH_2.CO_2H$. [225°]. Formed by heating aspartic acid with phthalic anhydride for 1 hour at 180° (Piutti, *G.* 14, 473; 16, 2). Tufts of prisms (from water). Decomposed into phthalic and aspartic acids by heating with HClAq. Boiling aniline forms aspartic acid and the phenylimides of phthalic and phthalyl-amido-succinic acids. Diphenylamine forms three di-phenyl-amic acids $C_8H_4O_2{:}N.C_2H_3(CONPh_2)(CO_2H)$ [180°], [204°], and [194°]; the first and third crystallises with aq, and all three yield a salt AgA′ and are decomposed by potash-fusion into aspartic acid, phthalic acid, and diphenylamine.

Salt.—CuA'_2 4aq: blue prisms.

Phenylimide 
$C_8H_4O_2N{:}CH\left<\begin{array}{l}CH_2.CO\ .\\CO\ .NPh\end{array}\right.$

[264°]. Formed from the acid and aniline. Small needles (from HOAc), nearly insol. alcohol.

Tetra-phenyl-diamide $C_8H_4O_2{:}N.C_2H_3{:}C_2O_2(NPh_2)_2$. Two isomerides, [273°] and [286°], are got by heating the acid with diphenylamine for 5 hours at 190°. Both are split up by HClAq at 200° into phthalic acid, diphenylamine, and aspartic acid.

PHTHALYL CHLORIDE *v.* *Chloride* of PHTHALIC ACID.

PHTHALYL-ETHANE *v.* *Anhydride* of PHENYL-ETHYL KETONE *o*-CARBOXYLIC ACID.

Di-phthalyl-ethane $C_{18}H_{10}O_4$ *i.e.*

$C_6H_4\left<\begin{array}{l}\text{—}C{:}CH.CH{:}C\text{—}\\CO.O\qquad\quad O.CO\end{array}\right>C_6H_4$.

Ethine-diphthalyl. [above 350°].

Formation.—1. Together with other products by the condensation of phthalic anhydride with succinic acid (Gabriel, *B.* 10, 1559; 19, 837).—2. By the action of conc. H_2SO_4 upon di-phenyl ethylene diketone di-*o*-carboxylic acid $C_6H_4(CO_2H).CO.CH_2.CH_2.CO.C_6H_4(CO_2H)$, or its ether.—3. By further elimination of H_2O from the (α) or (β) anhydrides $C_{18}H_{12}O_5$ of the latter acid (Roser, *B.* 17, 2770; 18, 3115).

Properties.—Yellow needles (from nitrobenzene), insol. water and alcohol. By boiling with alkalis it is converted into di-phenyl ethylene diketone di-*o*-carboxylic acid. Nitrous acid forms $C_{18}H_{10}N_2O_8$ a crystalline body decomposing at 160°, and converted by boiling HOAc into $C_{18}H_9NO_6$ [c. 240°].

Isomeride $C_{18}H_{10}O_4$. Formed as a by-product in preparing the preceding body by heating phthalic anhydride with succinic acid and NaOAc. Red needles with green lustre, not melted at 280°. Insol. water and alcohol, v. sol. hot aniline and nitrobenzene. Weak acid, forming unstable violet salts.

PHTHALYL-ETHYL-HYDROXYLAMINE *v.* vol. ii. p. 740.

PHTHALYL-HYDROXYLAMINE *v.* vol. ii. p. 738.

DI-PHTHALYLIC ACID $C_{16}H_{10}O_6$ *i.e.* $CO_2H.C_6H_4.CO.CO.C_6H_4.CO_2H$ (?) *Diphthalic acid.* [272°]. Formed by oxidation of diphthalyl (Ador, *A.* 164, 236), of (β)-dinaphthyl-diquinone $C_{20}H_{10}O_4$ (Korn, *B.* 17, 3021), and of di-phenyl-ethane dicarboxylic acid (Dobreff, *A.* 239, 68). Formed also by the action of alcoholic potash on diphthalyl dibromide (Graebe, *A.* 228, 132; 242, 221). Minute tables, almost insol. water, alcohol, and ether. Converted by boiling conc. KOHAq into phthalic acid. Dilute NaOHAq at 110° forms di-phenyl-carbinol tricarboxylic acid. Reduced by HI to $(CO_2H.C_6H_4)_2C_2H_4$. Alcoholic hydroxylamine hydrochloride forms, on heating, $C_{16}H_{13}NO_5$ [152°] and $C_{16}H_8N_2O_4$ [286°].

Salts: BaA″ 2aq: plates.—Ag_2A''.

Methyl ether Me_2A''. [192°]. Formed from Ag_2A'' and MeI. Lemon-yellow plates. By passing HCl into a hot solution of the acid in MeOH there is formed a colourless isomeric body [278°], partially converted into the methyl ether by heating with MeOH at 200°, and split up by HClAq at 150° into diphthalylic acid and MeCl.

Ethyl ether Et_2A''. [155°]. Got from Ag_2A'' and EtI. Lemon-yellow needles. The colourless isomeride [174°] is formed by ethylation with alcohol and HCl.

Anhydride $C_{16}H_8O_5$. [165°]. Formed by heating the acid with Ac_2O at 200°. Crystals (from HOAc), v. sol. chloroform.

DIPHTHALYLIMIDE $C_{16}H_9NO_3$ *i.e.*

$C_6H_4\left<\begin{array}{l}\text{———}C{:}C\text{—}\\C(NH).O\ O.CO\end{array}\right>C_6H_4$?

[above 360°]. Got by warming di-phthalyl-lactonic acid with NH_3Aq and by heating phthalimidine with NaOAc and phthalic anhydride or phthalimide at 220° (Graebe, *A.* 228, 137; 233, 246). Needles (from HOAc) forming a yellow solution in NaOHAq.

DIPHTHALYL-LACTONIC ACID $C_{16}H_{12}O_6$ *i.e.*

$C_6H_4\left<\begin{array}{l}\text{—}C{:}C(OH).C_6H_4.CO_2H\\CO.O\end{array}\right.$.

Diphthalaldehydic acid. Formed by warming diphthalyl, in an atmosphere of H, with alcoholic potash (Graebe a. Schmälzigang, *A.* 228, 126; *cf.* Ador, *A.* 164, 229). Crystals (from alcohol). When heated for some time at 220° it splits up into water and diphthalyl, which then melts above 300°. When quickly heated it decomposes at 235°–240° with partial fusion. Conc. H_2SO_4 converts it into diphthalyl. Its alkaline solution is yellow, but becomes colourless through absorption of atmospheric oxygen, yielding diphthalic acid.

PHTHALYL-MALONIC ETHER $C_{15}H_{14}O_6$, *i.e.*

$C_6H_4\left<\begin{array}{l}CO.O\\\text{——}C{:}C(CO_2Et)_2\end{array}\right.$.

[75°]. S. (ether) 7·1 at 9°; 58·8 at 35°. One of the products of the action of phthalyl chloride on sodium malonic ether (Wislicenus, *A.* 242, 23). Triclinic prisms (from ether), v. sol. alcohol.

Reactions.—1. Decomposed by long boiling with *water* into phthalic acid and malonic ether. 2. Hot *potash* forms malonic and phthalic acids. A solution of caustic potash at 0° forms

$C_6H_4\left<\begin{array}{l}CO.O\\\text{——}C(OH).CK(CO_2Et)_2\end{array}\right.$

whence acids liberate oily 'phthalyloxymalonic' ether, which quickly decomposes into phthalic anhydride and malonic ether.—3. NaOEt forms the compound  $C_6H_4\left<\begin{array}{l}CO.O\\ C(OEt).CNa(CO_2Et)_2\end{array}\right.$, crystallising in prisms, v. e. sol. water, yielding the cupric salt $Cu(C_{17}H_{19}O_7)_2$ 2aq and, on adding an acid, oily $C_{17}H_{20}O_7$. The dry salt, $NaC_{17}H_{19}O_7$ is converted by EtI at 100° into oily $C_{17}H_{19}EtO_7$, upon which alcoholic potash reacts forming the salt  $C_6H_4\left<\begin{array}{l}CO.O\\ C(OK).CEt(CO_2K)_2\end{array}\right.$ ppd. as very deliquescent plates on adding alcohol to its aqueous solution, yielding amorphous $Ag_3C_{13}H_9O_7$, and splitting up on acidification into ethyl-malonic acid and phthalic acid.—4. *Zinc-dust* and HOAc yield *o*-carboxy-benzyl-malonic ether (*v.* vol. i. p. 705).—5. Alcoholic NH_3 forms the diamides of malonic and phthalic acids.—6. *Sodium-malonic ether* forms yellow $C_{22}H_{24}Na_2O_{10}$, decomposed by boiling water into phthalyl-dimalonic ether, malonic ether, and phthalic acid.

Seminitrile  $C_6H_4\left<\begin{array}{l}CO.O\\ C:CCy.CO_2Et\end{array}\right.$ [c. 175°]. Formed from phthalyl chloride and sodium cyano-acetic ether in dry Et_2O (Muller, *C. R.* 112, 1140). White substance, sol. benzene.

Phthalyl-di-malonic ether $C_{22}H_{26}O_{10}$, *i.e.*  $C_6H_4\left<\begin{array}{l}CO.O\\ C(CH(CO_2Et)_2)_2\end{array}\right.$. [49°]. Formed from sodium-malonic ether and phthalyl chloride (Wislicenus, *A.* 242, 23, 80). Prisms (from alcohol), insol. water.

Reactions.—1. *Potash* forms a yellow solution containing $C_{22}H_{24}K_2O_{10}$, which separates as orange needles (containing 2aq) when Et_2O is added to a solution of the ether in alcoholic potash. Boiling aqueous potash forms phthalyl-diacetic acid $C_{12}H_{10}O_6$ [158°].—2. Alcoholic NaOH forms, in like manner, lemon-yellow $C_{22}H_{24}Na_2O_{10}$ 2aq, decomposed by hot water into malonic and phthalyl-dimalonic ethers and sodium phthalate. EtI at 100° converts the Na derivative into $C_{22}H_{24}Et_2O_{10}$, which yields ethyl-malonic ether on boiling with water.—3. The di-sodium derivative $C_{22}H_{24}Na_2O_{10}$ is converted by treatment with Ac_2O, phthalic anhydride, or phthalyl chloride into 'phthaloxy-dimalonic ether' $C_{22}H_{24}O_9$ or  $C_6H_4\left<\begin{array}{l}CO.C(CO_2Et)_2\\ C:C(CO_2Et)_2\end{array}\right.$ (?), S. (alcohol) ·57 at 14°, which crystallises from ether in needles melting at 117° when slowly heated and at 106° when quickly heated. 'Phthaloxy-dimalonic ether' is also one of the products of the action of phthalyl chloride on sodium malonic ether (Wislicenus, *A.* 242, 28, 61). It forms a yellow solution with aqueous K_2CO_3 and KOH. Alcoholic potash forms $C_{22}H_{23}KO_{10}$, which is the mono-potassium derivative of phthalyl-dimalonic ether. Zinc-dust and HOAc reduce 'phaloxy-dimalonic ether' to oily $C_{22}H_{28}O_9$.

PHTHALYL-PROPIONIC ACID $C_{11}H_8O_4$ *i.e.*  $C_6H_4\left<\begin{array}{l}CO.O\\ C:CH.CH_2.CO_2H\end{array}\right.$ [245°-248°]. Formed by boiling phthalic anhydride (5 pts.) with propionic anhydride (10 pts.) and sodium propionate (1 pt.) for 45 minutes (Gabriel a. Michael, *B.* 11, 1013, 1679). Slender needles. Converted by boiling KOHAq into phenyl ethyl ketone *o*-carboxylic acid. Reduced by sodium-amalgam to  $C_6H_4\left<\begin{array}{l}CO.O\\ CH.C_2H_4.CO_2H\end{array}\right.$ [140°] which yields BaA'_2 and AgA′ and is converted by boiling baryta-water into oxy-carboxy-phenyl-butyric acid $CO_2H.C_6H_4.CH(OH).C_2H_4.CO_2H$. H_2SO_4 at 100° forms $C_{20}H_{14}O_5$ [237°].

Salt.—AgA′: white powder.

Amide $C_{11}H_7O_3NH_2$. [195°]. Leaflets.

PHYCITE *v.* Erythrite.

PHYLLIC ACID $C_{72}H_{64}O_{16}$ (?). [170°]. S.G. 1·014. Extracted by alcohol from the leaves of the cherry-laurel, apple, almond, and elder (Bougarel, *Bl.* [2] 28, 148). Crystalline granules, decomposing at 180°. The K salt crystallises in needles, sl. sol. water, sol. alcohol.

PHYLLOCYANIN *v.* Chlorophyll.

PHYSALIN $C_{14}H_{16}O_5$. Occurs in the leaves of the winter cherry (*Physalis Alkekengi*), from which it may be extracted by chloroform (Desaignes a. Chautard, *J. Ph.* [3] 21, 24). Yellowish amorphous powder, with bitter taste, v. sl. sol. cold water and ether, v. sol. alcohol. Softens at 180°, and decomposes at a higher temperature. Sl. sol. acids, m. sol. NH_3Aq. Salt.—$Pb_3(C_{14}H_{15}O_5)_2O_2$: white pp., got by adding $Pb(OAc)_2$ and NH_3Aq to the alcoholic solution.

PHYSETOLEIC ACID $C_{16}H_{30}O_2$. [30°]. Occurs in sperm oil, and is perhaps identical with hypogæic acid (Hofstädter, *A.* 91, 177). Stellate groups of needles. Not affected by nitrous acid. —BaA'_2: crystals, sol. hot alcohol.

PHYSICAL METHODS USED IN CHEMISTRY. The object of this article is to present a general account of the chief physical methods of inquiry which are made use of in attacking chemical questions. In each section of the article it has been sought to lay down the principles of the method discussed, and to present, in a general way, the more important results that have been obtained. No section claims to give a complete account of the subject with which it deals. The following articles, which are not specially referred to in their alphabetical positions in the present article, should be consulted: Aggregation, States of, vol. i. p. 87; Atomic and molecular weights, vol. i. p. 336; Chemical and physical properties of bodies, connections between, vol. i. p. 730; Densities, relative, vol. ii. p. 370; Dissociation, vol. ii. p. 385; Molecular constitution of bodies, vol. iii. p. 410.

I. CAPILLARITY, METHODS BASED ON. The term 'capillarity' is given to that property of bodies which is the cause of the rise of liquids in narrow tubes, the spherical shape of raindrops and soap-bubbles, the spreading of oil on the surface of water, and many other phenomena.

The generally accepted theory by which these phenomena are connected and explained is due mainly to Laplace, and rests on the assumption that the parts of a body are held together by attractive forces which are insensible except at very small distances. We have evidence of the existence of these forces in the cohesion of bodies, in the latent heat of evaporation, which is merely the energy that has to be supplied to separate the parts from each other, and in the fact that at high pressures, when the parts of which a gas is composed are so near together that they never get altogether away from each other's influence, the compressibility is found to be greater than is required by Boyle's law. Though Laplace made no reference to molecules it is now usually supposed that the attractions in question are the forces acting between the molecules.

Imagine a molecule of a liquid surrounded by a sphere, whose radius is the distance at which the force ceases to be sensible. If the molecule is so far from the surface of the liquid that this sphere is entirely immersed, it will be on an average equally attracted all round, and no work will have to be expended to move it, but if it be so moved that part of the sphere is outside the surface, there will be a resultant force tending to draw it back again, so that to bring a molecule into the surface requires an expenditure of work. Now if we distort a given volume of liquid so as to increase its surface we bring more molecules into the surface, and we increase the potential energy of the liquid by an amount proportional to the increase of surface, or the total potential energy arising from this source is proportional to the extent of surface. Hence, since in the position of equilibrium of any system the potential energy is a minimum, the liquid will of itself assume such a shape that the surface is as small as possible consistently with other conditions, such as the action of gravity.

It is plain that what has been said is not restricted to liquids, but applies equally to solids and to the surface separating two different media. In the latter case a molecule at the surface of separation is acted on by both media, but unless the attractions are equal there will be a resultant force acting on it, and it will have potential energy by virtue of its position.

Capillary phenomena are often regarded as due to the external film of the substance being in a state of tension. It is not easy to imagine a tension at the surface of a solid, but the conception leads mathematically to the same results as the assumption of the existence of surface energy, and is practically only another way of stating the same thing, for we have seen that on the hypothesis of molecular attractions we arrive at the result that the surface tends to become a minimum, and this is equally well described by saying that it behaves as though it were in a state of tension. Further, the measure of the tension—that is, the total force acting across a line of unit length—is numerically equal to the potential energy per unit area, which is easily proved as follows. Imagine a rectangular piece of the surface a cm. long and b cm. wide—increase it to a rectangle a' cm. long and b cm. wide. Then we have produced $(a'-a)b$ sq. cm. of new surface, and if E is the potential energy per sq. cm. we shall have done $E(a'-a)b$ units of work. On the other hand, if T is the surface tension, the force acting on the side b will be Tb, and we have moved it through $a'-a$ cm., and hence have done $Tb(a'-a)$ units of work. These two measures of the work must be equal, and hence $E=T$; and since the rectangle can be taken anywhere on the surface and with its sides in any direction, it follows that the surface tension is the same at every point and in any direction.

It is to be observed that this tension differs from that of a stretched piece of indiarubber, for instance, in the fact that it does not depend on the amount of stretching. No matter how much a soap film is extended, the tension remains the same until the film becomes so thin that there are only a few molecules in the thickness.

The surface tension, then, is a consequence of the molecular attractions which tend to draw the molecules as close together as possible. In order to balance this tendency and to allow the substance to be in equilibrium, Laplace imagined the existence of an internal hydrostatic pressure, which, from the value of the latent heat, is calculated by Stefan to be about 1300 atmospheres in the case of water. The potential energy due to this pressure is proportional to the volume, which is constant in most capillary phenomena, and hence has no effect on the equilibrium position.

The forms of crystals are probably conditioned to some extent by capillary forces. Most of the properties of crystals being different in different directions, the potential energy of a surface may be expected to depend on its direction, and those faces will be formed which have least energy. Further, as a large crystal has less surface in proportion to its volume than a small one, the familiar phenomenon of the large crystals absorbing the small ones is explained by the loss of potential energy resulting from the operation (*v.* Liveing, *Camb. Phil. Trans.* 14, 370).

If two immiscible fluids are in contact with a solid, the surface separating them meets that of the solid at a constant angle, called the angle of contact. The most important case is where one of the fluids is air and the solid is glass. Many experiments have been made to determine this angle, the conclusion being that in most cases it is probably zero, but on this point see Magie (*W.* 25, 429), Quincke (*W.* 27, 219), and Worthington (*P. M.* [5] 20, 65).

The constant which is most commonly used is the surface tension as defined above, but Quincke and some others use another called the specific cohesion, denoted by a^2, which is twice the surface tension divided by the density of the liquid, or the height to which the liquid would rise in a tube of unit radius.

The following are the principal methods that have been used in determining these constants: 1. By determining the rise of liquids in capillary tubes (Quincke, *P.* 139, 8; Frankenheim, *J. pr.* 23, 401).—2. By weighing or measuring the drops from a rod or pipette (Quincke, *P.* 135, 621; Duclaux, *A. Ch.* [5] 13, 76; Linebarger, *Am. S.* 44, 83).—3. By measurement of large drops or bubbles (Quincke, *P. M.* [4] 41, 245; Eötvös, *W.* 27, 448; Worthington, *P. M.* [5] 20, 51).—4. By determining the force required to detach a disc or ring from the surface of a liquid (Weinberg, *Z. P. C.* 10, 34).

Mendeléeff states as one of the characteristics of a perfect liquid that its surface tension should be a linear function of its temperature, and Selby (*P. M.* [5] 31, 430) has given thermodynamical reasons for this relation. The subject has been investigated experimentally by Frankenheim, Weinberg, and others, and it is found that the equation $\gamma = a - bt$ holds approximately, where γ is the surface tension, t the temperature, and a and b are constants; hence by determination of γ at two temperatures we can calculate roughly the temperature $\frac{a}{b}$ at which the surface tension is zero—that is, the critical temperature. Eötvös extends this result by showing that the rate of change with temperature of $\gamma v^{\frac{2}{3}}$, where v is the molecular volume of the liquid (and hence $\gamma v^{\frac{2}{3}}$ is proportional to the energy of the amount of surface which contains a given number of molecules), has a constant value which is the same for all liquids.

The only measurements of the surface tensions of pure liquids which have been carried out extensively are those of Schiff (*A.* 223, 47; and *G.* 14, 368). Schiff determined the surface tensions of a large number of organic substances at their boiling-points, and divided the observed values by the molecular weights, denoting the quotient by N. This quantity was found to be in general unchanged by the substitution of one carbon atom for two hydrogen atoms, of one oxygen for three hydrogens, and similarly for other elements, so that each atom had its hydrogen equivalent, and compounds with the same total of hydrogen equivalents gave the same value for N. Taking N for ordinate, and x, the total hydrogen equivalent, for abscissa, Schiff plotted a curve from which he obtained the relation

$$\log N = 2{\cdot}8155 - {\cdot}00728x - \log x.$$

This equation enables us to calculate the surface tension of a liquid compound from its formula.

There are many exceptions to the law that each atom has a fixed hydrogen equivalent. For instance, C must be put equal to 3H in the free fatty acids instead of 2H as in most compounds; Cl generally has the value 7H, but when several chlorine atoms are attached to different carbons in a compound it has the value 6H; Br is usually equivalent to 13H, but sometimes to 11H, and so on.

A few preliminary measurements of the capillary constants of the surface separating water and organic liquids which do not mix with it, have been made by Linebarger (*Am. S.* 44, 83), by allowing the liquid to drop through the water, upwards or downwards, according to its specific gravity, and counting the drops from a given volume. The results already published show that the introduction of two methyl groups in the meta- position into a benzene ring does not affect the surface tension. while if they are in the para- position the surface tension is greatly diminished.

The surface tension of an aqueous solution of a salt is greater than that of water, and increases proportionately to the amount of salt present. Quincke (*P.* 160, 337, 560) found that for solutions of chlorides of equivalent concentrations—that is, containing the same amount of chlorine per c.c.—the constant of proportionality is the same; but Volckmann (*W.* 17, 353), on repeating the work, concluded that the agreement is not within the errors of experiment. Traube (*J. pr.* [2] 31, 192) showed that the capillary constant of a 10 p.c. solution of water in alcohol is not raised, like that of water, but is lowered, by the presence of a dissolved salt.

Determinations of the surface tensions of solutions of organic substances in water have not hitherto led to any important general laws. Such substances lower the surface tension but not proportionally to the concentration, as appears from the work of Duclaux (*A. Ch.* [5] 13, 76), and of Traube (*B.* 17, 2294; *J. pr.* [2] 31, 177; 34, 292). The former gives the law that if aqueous solutions of two alcohols, or of two acids, have the same surface tension, the percentage compositions of the two solutions will have a constant ratio. Traube's work confirms this result, but leads to nothing farther of interest beyond the fact that solutions of isomerides have not generally the same surface tensions. J. W. C.

II. CRYSTALLOGRAPHIC METHODS; *v.* CRYSTALLISATION, vol. i. p. 278; and ISOMORPHISM, vol. iii. p. 88.

III. DIALYSIS AND DIFFUSION, METHODS BASED ON. When a solid is dissolved in a solvent a movement of the particles occurs from the places where the solution is more concentrated to the places where it is less concentrated, and continues until the concentration is uniform throughout. Similarly when gases which do not react chemically are mixed, movements of the particles take place until the gases are equally distributed throughout the space. The mixing of gases or liquids, by reason of the movements of their particles, is called *diffusion.* When the diffusion of a liquid is accompanied by a total or partial separation into unlike bodies, the process is generally called *dialysis*; this process is usually effected by allowing the diffusion to take place through an animal or vegetable membrane. The chemical applications of diffusion are chiefly connected with the diffusion of substances in solution, and generally in solution in water.

Graham (*T.* 1850. 1, 805; 1851. 483) was the first to measure the rates of diffusion of different compounds, in aqueous solution, without a separating membrane. He nearly filled glass jars with the various solutions, carefully poured water on the top of the solutions, placed the jars in glass dishes, and filled these with water until the water extended in the dishes about 3 c. above the tops of the jars. The dishes were set aside for some time; when the process was to be stopped, glass plates were slid over the mouths of the jars, which were then removed, and the quantities of substance in the liquids outside the jars, called the *diffusates* by Graham, were determined.

Graham found that the quantities which diffused varied much according to the compositions of the diffusing substances. The quantity of a specified substance which diffused in a determinate time was found to be nearly proportional to the concentration of the original solution. Graham also found that diffusion was able to effect a tolerably complete separation of two salts whose rates of diffusion differed considerably. He looked on his results as showing that nearly equal quantities of chemically similar salts diffused in equal times.

A few years after Graham's fundamental experiments, Fick, reasoning from Fourier's theory of the conduction of heat, came to the tentative conclusion that *the quantity of a salt which diffuses through a stated area is proportional to the difference between the concentrations of two areas infinitely near one another.* Assuming the truth of this statement, a definition was obtained for the *diffusion-constant* of a salt as *the quantity of a salt which diffuses through unit area in unit time, when unit difference of concentration prevails throughout unit distance.* A long series of researches by Beilstein (*A.* 99, 165), Simmler a. Wild (*P.* 100, 217), Stefan (*W. A. B.* 79, 161), and especially by Weber (*W.* 7, 469, 536) and Graham (*T.* 1861. 183), has fully confirmed Fick's law, and has given measurements of the diffusion-constants of many substances. Attention should be drawn, in this connection, especially to Graham's method of allowing salts to diffuse in water gelatinised by starch, gum, &c. (*T.* 1861. 183; *v.* also Voigtländer, *Z. P. C.* 3, 316). In 1880, Long (*W.* 9, 613) made a number of determinations of rates of diffusion; he divided the numbers obtained by the molecular weights of the salts used, and thus obtained figures which represented the number of molecules of each salt which diffused under the same conditions. The results showed somewhat regular arrangements of the molecular diffusion-values. For instance, Long found that the haloid compounds of K had nearly the same value, that the sulphates of Mg, Zn, Mn, Co, Ni, and Cu had approximately equal values, and so on.

Marignac (*A. Ch.* [5] 2, 546 [1874]) followed up Graham's observations on the simultaneous diffusion of pairs of salts, and arrived at the important result that the order of the rates of diffusion of the salts of any acid is independent of the nature of the acid, and that the order of the rates of diffusion of the salts of a metal is independent of the nature of the metal. Marignac was thus able to construct a table showing the order of the diffusion-coefficients of acid radicles, on the one hand, and of metals, on the other hand. The table is as follows:—

Cl, Br, I	H
NO_3	K, NH_4
ClO_3, ClO_4, MnO_4	Ag
F	Na
CrO_4	Ca, Sr, Ba, Pb, Hg
SO_4	Mn, Mg, Zn
CO_3	Cu
	Al

Crystalloids and colloids. Graham observed that the rates of diffusion of different substances differ much. He found certain substances which diffused in water with very great slowness; these substances included gums, tannin, albumen, caramel, &c. Inasmuch as the substances which diffused comparatively rapidly generally assumed crystalline forms when they solidified, while substances which diffused very slowly solidified in amorphous forms, Graham called the former *crystalloids* and the latter *colloids.* The solution in water of crystalloids is usually accompanied by thermal changes; the solutions boil and freeze at temperatures different from the boiling- and freezing-points of water, and the properties of the solutions differ considerably from those of the solvent. On the other hand, the solution in water of a colloidal substance is not attended with any marked changes.

The solution of a colloidal substance allows the diffusion through it of a crystalloid, in solution, but scarcely permits the diffusion of another colloid. If, then, a solution containing a crystalloid and a colloid is separated from water by a colloidal membrane, such as animal or vegetable parchment, the crystalloid will diffuse through this membrane into the water outside, but the colloid will be retained in the interior liquid; in this way colloids can be separated from crystalloids by diffusion; this process was called *dialysis* by Graham.

By means of dialysis, Graham prepared many compounds in a colloidal, or jelly-like form (*T.* 1861. 183). Most inorganic colloidal compounds were found to exist in two forms; one soluble in much water, and the other gelatinous and insoluble in water. For instance, an aqueous solution of silicic acid, containing 14 p.c. of this acid, was obtained by adding a solution of sodium silicate to excess of dilute HClAq, and dialysing (by pouring into a flat saucer formed of parchment paper which was floated on pure water) for some days, until the liquid inside the dialyser ceased to give a reaction with $AgNO_3Aq$; the liquid in the dialyser was then concentrated by boiling in a flask. The solution of silicic acid gelatinises after a few days, or at once by addition of a trace of an alkaline or earthy carbonate, or by a few bubbles of CO_2, or by certain soluble colloids, such as gelatin or soluble alumina. The gelatinised colloidal silicic acid is insoluble in water.

Graham prepared soluble and gelatinised colloidal forms of Al_2O_3, Fe_2O_3, Cu_2FeCy_6, Cr_2O_3, stannic acid, &c. Other soluble inorganic colloidal compounds have been obtained in recent years.

Graham looked on colloids as very different in their constitution from crystalloids. He regarded colloids as prone to undergo changes which take place very slowly; he thought it possible that the molecule, or molecular aggregate, of a colloid is formed 'by the grouping together of a number of smaller crystalloid molecules.' Colloids, according to Graham, are capable of loosely combining with various proportions of water; this process of 'gelatinous hydration' was regarded by Graham as being 'as truly chemical as that of crystalline hydration.'

Graham's views on the nature of colloids have been confirmed, on the whole, by more recent work. J. M. van Bemmelen has especially studied the hydration of colloids. He gives the name *hydrogels* to those gelatinous hydrates which contain varying quantities of water not agreeing with any definite formula; he describes the reactions of hydrogels with gases and liquids to form what he calls *absorption-compounds*, and discusses the part played by such compounds in the soil (*L. V.* 35, 69; Abstract in *C. J.* 54, 985). For van B.'s work on various individual colloids *v. R. T. C.* 7, 37, 69, 75, 87, 106, 114; Abstracts in *C. J.* 54, 1157-1162.

Picton (*C. J.* 61, 137) and Picton a. Linder (*C. J.* 61, 114, 148) have recently prepared a number of soluble colloidal forms of metallic sulphides, such as CuS, HgS, As_2S_3. The colloidal solutions were obtained (1) by pouring solutions of the metallic salts into H_2SAq, into which H_2S was continuously passed, and dialysing, after removal of excess of H_2S by a current of H; (2) by passing H_2S into water with metallic hydrates in suspension; (3) by suspending freshly ppd. metallic sulphides in water and passing in H_2S. All the solutions contained combined H_2S, and were therefore solutions of hydrosulphides. The solution of As_2S_3 contained about 5 g. As_2S_3 per litre, and that of HgS about 10 g. per litre. These colloidal solutions were shown to contain solid particles. In some cases the particles were visible through a powerful microscope; in other cases the particles were proved to be present by passing a ray of bright light through the liquids, and showing the scattering of polarised light which thus occurred. Solutions of 'colloidal molybdic acid,' and colloidal silicic acid containing free HCl, seemed to be free from solid particles. Solution of colloidal antimony sulphide showed no particles under the microscope, but the presence of particles was revealed by the passage of a beam of light; after keeping for about ten days, particles had formed sufficiently large to be seen by the help of the microscope; and after some weeks the Sb was all ppd. as Sb_2S_3. In this case the passage could be followed from a liquid containing very minute particles, whose presence was detected only by the fact that they scattered light, to a liquid containing particles sufficiently large to be seen under the microscope. On the other hand, a solution of $CrCl_3$ in water containing a little chromous acetate was able to scatter light, and therefore contained solid particles; but after a few days the particles were no longer present. In this case the passage could be traced from a liquid containing very minute particles to a liquid free from such particles.

The colloidal solutions did not diffuse, with one exception—namely, arsenious sulphide. The diffusible solution was obtained by running As_2O_3Aq into H_2SAq, into which H_2S was continuously passed, and removing excess of H_2S by a current of H. This solution showed no particles under the microscope, but as it scattered polarised light particles were present in it. The liquid was put into a small wide-mouthed bottle, which was placed in a beaker and covered with water; a distinct amount of As_2S_3 had diffused in one day, and after eleven days about 12½ p.c. of the As_2S_3 was found in the diffusate. This colloidal solution therefore presented the interesting phenomenon of a liquid containing solid particles capable of scattering polarised light from a beam passed through, and yet able to diffuse in exactly the same way as true solutions undergo diffusion.

Picton a. Linder consider that their experiments establish 'a good *prima facie* case for the belief that there is a continuous series of grades of solution passing without break from suspension to crystallisable solution.' They look on the very small particles in some of these colloidal solutions as large molecular aggregates, and they think that these aggregates become very small in the solutions which can diffuse, and that the forces by which the aggregates are held in solution 'become more definitely those of chemical attraction.' (In connection with colloidal solutions *v.* Paterno, *Z. P. C.* 4, 457; and Barus a. Schneider, *Z. P. C.* 8, 278.)

Diffusion of gases. The fact was observed by Dalton (*P. M.* 24, 8) that if a heavier gas is placed in a bottle which is connected with another bottle containing a lighter gas, and placed beneath the first bottle, after some days the gases will be equally mixed in both bottles. The same fact was observed, and some measurements were made, by Berthollet (*Mém. S. d'A.* 2, 463). Graham (*Q. J. S.* 1829. 74; *P. M.* 1833. 175, 269, 351) made a great many measurements of the rates of diffusion of different gases. For most of these he employed a *diffusiometer*, which consisted of a glass tube about 20 cm. long and about 1¼ cm. diameter, having a plug of plaster of Paris in one end extending inwards about ½ cm., and graduated from this end downwards. The tube was filled with the gas under examination and placed in water; when the level of the water in the tube had become constant, the total volume of gas now in the tube was measured, and the amounts of air and original gas contained in the tube were determined. With gases lighter than air there was a decrease in the contents of the tube, as the lighter gas passed out through the porous plate more quickly than air passed in; with gases heavier than air there was an increase in the gaseous contents of the tube, as air passed in more quickly than the heavier gas passed out.

The conclusion which Graham arrived at was that 'the diffusion or spontaneous intermixture of two gases in contact is effected by an interchange in position of indefinitely minute volumes of the gases, which volumes are not necessarily of equal magnitude, being, in the case of each gas, inversely proportional to the square root of the density of that gas.'

Modifications in Graham's apparatus have been made, and many determinations of the rates of diffusion of gases have been conducted; the results have fully confirmed Graham's law, which may be stated in the form $c:c' = \sqrt{d'} : \sqrt{d}$, where c and c' are the diffusion-rates of two gases whose relative densities are d and d'.

It is evident that Graham's law of diffusion gives a means for finding the molecular weights of gases; inasmuch as the law enables measurements to be made of the relative densities of gases, and the density of a gas, referred to hydrogen, multiplied by 2 is (approximately) the molecular weight of that gas. For a description of an instrument for this application of the law of diffusion *v.* Bunsen's *Gasomet. Methoden*, p. 160.

IV. DYNAMICAL METHODS. Several methods used in attacking chemical problems may be put together under this general title: *v.* Chemical change, vol. i. p. 731; Affinity, vol. i. p. 67; Aggregation, States of, vol. i. p. 87; Dissociation, vol. ii. p. 385; Equilibrium, Chemical, vol. ii. p. 434; Molecular constitution of bodies, Theories of, vol. iii. p. 410.

V. ELECTRICAL METHODS.

Historical.—The history of the science of electricity divides itself into two well-defined periods, the boundary between which lies at the close of the last century, and is marked by Volta's discoveries concerning the production of electricity when different substances are brought into contact. The investigations in the older period, when only the phenomena of frictional electricity, characterised by small quantity and high tension, were known, showed no connection with chemical problems. It is true, Deimann and Paets van Trostvijk had decomposed water by means of the electrical machine; this effect was, however, assigned as due more to the high temperature of the electric spark than to a specific property of electricity.

It is only with Galvani's discovery of the electricity which appears when different substances are brought into contact, and with the scientific investigation of this discovery by Volta, that the period of *electro-chemistry* begins. This branch of science is thus of nearly exactly the same age as the current century. It was by means of the *pile* as constructed by Volta that chemical changes were recognised to be essential phenomena concurrent with the passage of an electric current through certain substances. Directly this apparatus became known, Nicholson and Carlisle (1800) used it for the decomposition of water, and since then the fact that there is a close connection between chemical and electrical phenomena has always been present to the mind of investigators. The mysterious and unexpected mode of action of this apparatus soon revived the hope that by means of it the problem of *vital activity* might be fathomed. Consequently, the electric current was made to pass through various animal fluids, such as blood, protein, &c., with the object of following the changes produced by this influence, and thus obtaining information concerning the processes taking place in the organism. It was found that, along with other effects, a basic reaction was always observed at one pole, and an acid reaction at the other. On further investigation it was found that the acid and the base still appeared, even when water was taken instead of the animal fluids, and thus the electric current seemed to be a means for producing acids and bases from pure water. This is the point at which the classical researches of Humphry Davy began. In order to decide whether acids and bases were really produced from pure water by means of electricity, he repeated the experiments. He soon recognised that the vessels in which the water was contained exerted a determinant influence on the results; he proved that very small quantities of the substance of the vessels were always dissolved by the water, and that vessels of glass, clay, basalt, &c., were subject to this influence. The electric current had the power of decomposing the very small quantities of saline matter present into acids and bases, and of accumulating these at the poles, where they could be detected easily. Only vessels of gold proved to possess the necessary resistance, and when these were used not the least quantity of either acid or base was obtained from pure water.

After Davy had thus become acquainted with the great power of decomposing compounds possessed by the electric current, he proceeded at once to submit the most diverse substances to its influence. By means of the large batteries of the Royal Institution, which had been constructed according to his plans, he succeeded in obtaining great effects; he decomposed the alkalis, and isolated the metals potassium and sodium.

At the present day it is difficult to imagine the impression which this discovery made on his contemporaries. It was not scientific circles only that were full of it; the public at large and the daily press occupied themselves most diligently with this fact. Everyone who could procure some dozens of copper and zinc plates tried to repeat the experiment, and gave an account of it. Napoleon, who then had just nearly reached the zenith of his power, proceeded at once to have larger batteries constructed in order to smooth the way for similar discoveries by the French scientists. He also offered great prizes for scientific works dealing with voltaic electricity.

Davy's discovery was of great importance for the development of the science of chemistry, because it enabled the alkalis to be classed with other basic metallic oxides. Chemical classification was thus simplified considerably. The investigations of Davy were, however, without influence on the knowledge of chemical affinity, sound as were the views held by this man of genius concerning the relation between chemical and electrical processes.

It was at this same time that the two Swedish naturalists Berzelius and Hisinger carried out work which then, it is true, did not attract anything like the same attention as had justly been aroused by Davy's investigations, but which had an even more lasting influence on the later development of scientific chemistry. Davy's experiments dealt chiefly with the fact that the electric current split compounds into their constituents, and aimed at the isolation of these constituents. Berzelius and Hisinger went a step farther; they tried to grasp the laws underlying this decomposition, and from these they developed a theory concerning chemical compounds. The generalisations under which Berzelius and Hisinger comprised their results were as follows:

(*a*) Chemical compounds are decomposed by the electric current, and their components collect at the poles.

(*b*) The combustible substances, the alkalis, and earths go to the negative pole; oxygen, the acids, and oxidised substances go to the positive pole.

The fact that Berzelius had experimented chiefly on the salts of the alkalis determined the theoretical conception of electrolysis. Since acids and bases appeared at the poles when alkali salts were electrolysed, acids and bases were considered to be the components of salts. Berzelius assumed further that a similar binary division prevailed throughout the whole domain of chemical compounds. He conceived every atom as endowed with a definite quantity of positive or negative electricity, and this led him to distinguish between positive and negative elements, and to arrange the elements in a series, beginning with the most positive down to the most negative. It was thus that for Berzelius the combination of elements with each other was simply an act of electrical attraction; according to him the thermal and optical effects which are produced along with chemical combination are due to the same cause as the corresponding phenomena which accompany the electric spark. It is true that at this point Berzelius, with the caution peculiar to him, himself brings forward the objection that when the opposite electricities have neutralised each other a further cause of their keeping together is no longer present. It seems, however, that he did not consider this difficulty of sufficient importance to give up his theory for it.

When a positive and a negative atom interact, their electricities, according to Berzelius, are in general not completely neutralised, as the quantities of electricity present differ according to the nature of the atoms. The compound formed thus retains a surplus of positive or of negative electricity, and acts therefore similarly to an element, but less intensely. It is in this way that compounds can again combine with each other to form compounds of a higher order, and so on, and thus is brought about a binary constitution of all compounds.

This electro-chemical theory of Berzelius, which he developed more fully at a later time, has exerted a very marked influence on the progress of chemistry, since it has impressed on this science the form which was the only one recognised from 1810 to 1840. It was characteristic of this phase that after this first investigation Berzelius did not again undertake any experimental work on the action of electricity on chemical compounds. The places wherein the Berzelian theory was weak from the physical point of view were not considered at all, as the theory was used only for the purposes of chemical classification; no attempt was made to explain by means of it the problems of chemical affinity.

After an almost uncontested reign of twenty years' duration the theory of Berzelius proved itself insufficient to follow the progress of the science. Since it was deduced from the phenomena of the decomposition of compounds by electricity, it was not surprising that it could not represent the chemical relations of organic compounds, which, as a rule, are not decomposed by electricity. Investigations on this subject proved more and more conclusively that in chemical compounds individual atoms could be substituted by other atoms or groups of atoms, quite independently of the 'electro-chemical' nature of the elements; in the most conspicuous and best-known examples it was a question of the substitution of 'positive' hydrogen by 'negative' chlorine. Such a process Berzelius considered to be quite impossible in the light of his theory.

But it was not this proposition of the electro-chemical theory alone, but the whole foundation of Berzelius's system, which was made doubtful and proved to be untenable by the newer development of organic chemistry. The theory of the *binary* constitution of chemical compounds was no longer capable of being brought into accord with facts, which rather led to the *unitary* conception of substances. Closely connected with this development is the establishment of the conception of the chemical molecule, a conception which assigned a sharply-defined existence to the combinations of the elementary atoms, and which led to the view that these structures would split up in the most diverse ways, according to the nature of the influences to which they were subjected, although no such division appeared pre-existing in the molecule.

At the same time (after 1840) at which purely chemical facts had proved Berzelius's system insufficient for the domain of organic chemistry, the insufficiency of its physical foundations was also made apparent. This happened in consequence of Faraday's fundamental work.

A lively discussion concerning the cause of the production of electricity in the galvanic pile had been carried on ever since the days of Volta. While Volta and his successors sought for the cause of the electric tension at the extremities of the pile in the contact of the metals, a number of other workers held to the opinion, as first expressed by Fabbroni, that the cause of galvanic electricity was to be found in the chemical processes which take place in the pile. It is not possible to enter here into the history of the contest which has lasted up to the present day. Faraday attempted to solve the problem, and in so doing he discovered the electrolytic law (1834) which goes by his name.

This law affirms, firstly, that when electricity passes through a body which is decomposed by it—that is, through an *electrolyte*—the quantity of substance decomposed is proportional to the quantity of electricity that has passed through. Secondly, the law affirms that when the same quantity of electricity passes through different electrolytes, the quantities of the different substances which are thereby decomposed are to each other in the ratio of their chemical equivalents.

These two generalisations primarily supported the chemical theory of galvanic electricity, as according to them a galvanic current is never possible without a corresponding chemical process. At the same time, however, they were in unresolvable contradiction to the foundations of the theory of Berzelius as conceived by him; since, if one and the same quantity of electricity is always necessary in order to decompose chemically equivalent quantities of any substances, it cannot be true that different quantities of electricity cause their combination, in which act they neutralise each other. Berzelius was keenly alive to this contradiction, but as he did not wish to doubt his own theory he preferred to doubt the laws of Faraday, and he continually argued against them.

It was through the work of Daniell (*T.* 1839. i. 97, and 1840. i. 209), which followed up the researches of Faraday, that the electro-chemical theory was fought on the very ground from which it had sprung. The results of the electrolysis of neutral salts, such as potassium sulphate or sodium chloride, when the two electrodes of the electrolytic cell were separated by a porous diaphragm, showed that detonating gas (or hydrogen) was formed in the same quantity as in a voltameter with dilute sulphuric acid inserted in the circuit, and besides this an equivalent quantity of the salt was decomposed into acid and base. This phenomenon cannot be brought into accordance with the law of Faraday otherwise than by assuming that electrolysis does not split up the salts into base and acid, but rather into the metals and into the elements (such as Cl) or radicles (such as SO_4) combined with these. Thus, when potassium sulphate is electrolysed, hydrogen and oxygen are only secondary products, just as the free acid and the base are only secondary products; the salt K_2SO_4 splits up rather into free potassium K_2, which acts on the water, forming potash ($K_2+2H_2O = H_2+2KOH$), and into the radicle SO_4, which with water gives sulphuric acid and oxygen ($SO_4+H_2O=H_2SO_4+O$). Correspondingly, when copper sulphate is electrolysed we obtain, not copper oxide and sulphuric acid, but on the one side metallic copper, and on the other side SO_4 which gives sulphuric acid and oxygen. Thus Daniell arrived at the conclusion that the conception of salts as consisting of base and acid would have to be given up, and that they rather consist of a metal and a simple radicle (Cl, S, &c.), or a compound radicle (SO_4, NO_3, &c.), and he further pointed out that Davy had already expressed similar ideas.

The same result to which the application of Faraday's law led in this case had meanwhile been arrived at by chemical methods. After Graham (*T.* 1833. ii. 253) had reduced the differences exhibited by the salts of phosphoric acid to differences in the amounts of water held by the acid, and had thus founded the theory of the polybasic acids, Liebig (1838), in his celebrated paper (*A.* 26, 113), enunciated the theorem that all acids must be looked on as hydrogen compounds, and that the formation of salts consists in the replacement of this hydrogen by metals or metallic radicles. By means of this conception the unnatural division between the salts of oxy-acids on the one hand, and the halogen compounds of metals on the other, was again put aside. The necessity for such a division had been felt by Berzelius to be a great trouble, and to do away with it he had for long clung tenaciously to the assumption that the halogens were oxygen compounds.

The first attempt to utilise the facts of galvanism for chemistry had failed. In 1850 Berzelius's electrochemical theory had but few supporters left. Still the consciousness survived that the mistake had lain in the form in which the relation between chemical and electrical properties had been represented; and it continued to be recognised that this relation actually did exist, and that it was of the greatest importance. A sign of this recognition is found in the fact that although Berzelius's theory had been rejected, the elements which form bases were still called *positive* and those which form acids were called *negative*. In fact, the electrochemical contrast of the two constituents of salts is a fact which becomes obvious with each electrolysis, and which, therefore, cannot be doubted. It was only necessary to modify the view of Berzelius and to say that it is not the acids and bases (or more correctly their anhydrides) which are the constituents of salts, but rather it is the metal and the acid radicle. This modification of the electrochemical theory has, however, scarcely left any traces in the development of the chemistry of that time. The reason of this is that compounds of the nature of salts receded quite out of the foreground of interest. Organic chemistry, which at that time developed brilliantly, dealt with substances very few of which could be decomposed by the electric current, which were not electrolytes, and for which, therefore, the electrochemical contrast did not exist. The unitary conception was consequently involuntarily extended to the salts, and the important distinction between electrolytes and non-electrolytes was not at all taken into account by chemists. It is true that Faraday attempted to account for these two classes of bodies by supposing that in the one case the number of positive and negative atoms was the same, but in the other case these numbers were different; but this rule proved to be incorrect, and for a long time these relations were neglected because they could not be grasped scientifically. After the refutation of the erroneous views of Berzelius, people thought themselves justified in altogether ignoring the electrochemical relations.

This was the condition of electrochemistry till quite recently. The only attention it received was from the hands of some physicists, and it is only natural that purely chemical problems did not fare particularly well under these circumstances, the more so as even up to the present day it often happens that from this side the electrolysis of dilute sulphuric acid is represented as the electrolysis of water 'which has been made conductive by an addition of sulphuric acid. Although the direct furtherance thus given to chemistry was insignificant, yet the indirect effects were important. If it is possible to speak to-day of the development of a new electrochemical theory, it is almost exclusively to these physicists that we owe the means for so doing.

The first investigator to be mentioned at this point is Hittorf. He connected his work with the experiments of Daniell, and took up the consideration of a phenomenon which had remained incomprehensible to the latter. When Daniell experimented with sulphuric acid in his apparatus, he found that besides the electrolysis of the acid a change in the concentration had occurred; at the negative pole the acid solution had become more dilute, at the positive pole it had become more concentrated. It occurred to Hittorf that this phenomenon must be due to the different velocities with which the two constituents or ions of sulphuric acid—that is, 2H and SO_4—travel through the liquid. If, for instance, the hydrogen remained at rest and the group SO_4 alone moved, it would follow that after the electrolysis of one molecular weight of sulphuric acid, there must be an increase, by that amount, in the concentration at the positive pole towards which SO_4 had travelled. If, on the other hand, the hydrogen alone travelled, the concentration would remain unchanged. Now, it had been found by Daniell that the increase in concentration at the positive pole was equal to less than a quarter of the quantity of acid electrolysed; the necessary conclusion was, therefore, that both ions travelled, but that SO_4 moved much more slowly than $2H$. Hittorf proved by a great number of careful experiments (*P.* 89, 177; 98, 1; 103, 1; 106, 337) that this conclusion always agreed with observed facts. He then used the knowledge thus gained to answer chemical questions, for the solution of which no other means existed at the time. But in spite of their great importance, Hittorf's results have been all but completely ignored by chemists.

These experiments afforded verification of the conclusion that the more immediate components of salts—or what is the same, the ions of salts—really are the metal and the acid radicle. At the same time electrolysis furnished Hittorf with the means of solving certain old problems. Thus, for instance, opinion was divided as to whether potassium platinichloride and similar salts should be considered as double salts—for example, as $2KCl$ and $PtCl_4$—or as salts of chloroplatinic acid H_2PtCl_6. Hittorf submitted sodium platinichloride to electrolysis. If it consisted of $2NaCl + PtCl_4$, it followed that sodium and platinum were the positive ions and chlorine the negative; if, on the other hand, it was Na_2PtCl_6, the ions would be $2Na$ and $PtCl_6$. In the first case, therefore, the platinum must travel to the negative pole, in the other case to the positive. Experiment decided for the latter view; the platinum did not go to the negative pole, as the metals generally do, but travelled with the chlorine to the positive pole, thus proving itself to be a constituent of the acid radicle. In a like manner Hittorf decided quite a number of similar questions.

During these investigations, Hittorf drew attention to another point, which at a later time proved to be of the utmost importance. The fact that electrolysis can be started by the weakest currents is in contradiction to the usual chemical views, according to which the constituents of salts, such as KCl, Na_2SO_4, &c., are held together by very strong affinities. At the same time, Hittorf emphasised the fact that those substances which conduct electrolytically are the most ready to interchange their constituents. This fact also is against the assumption of a specially firm binding together of the constituents of salts. Occasion will be found later to refer to this remark.

There are other parts of the science of electricity, besides the phenomena of electrolysis, in which the chemical nature of substances has to be considered. These are the electrical conductivities of electrolytes, the electromotive force of galvanic cells, and galvanic polarisation. These fields have been cultivated till quite lately only by physicists to whom purely chemical questions were foreign.

The electrical conductivity of an electrolyte is a quantity the determination of which was formerly attended with great difficulties. These difficulties occur because the ions which separate where the electric current enters or leaves the liquid 'polarise' the electrodes, and thus produce new and unknown electromotive forces. Details of the various attempts which have been made to overcome this difficulty will be given later. It was, however, only in 1880 that, after long and varied preliminary investigations, F. Kohlrausch (*W.* 11, 658) indicated a really practical and accurate method. As soon as the values of the electrical conductivities of electrolytes could be determined easily, by Kohlrausch's method, important relations soon came to be recognised between the conductivities and the chemical properties of electrolytes. The most important of these relations, the discovery of which was made by Arrhenius (*Bigh. Swensk. Ak.* 8, Nos. 13 and 14, 1884), lies on the path opened up by Hittorf. The fact that substances capable of conducting the current and of being electrolysed are also specially capable of entering into chemical reactions, which was emphasised by Hittorf, can now be made definite by saying that both powers are nearly proportional for different electrolytes.

From this discovery there has grown a new electrochemical theory, which, in its entirety, will be expounded later on.

The other problem concerning the connection between the electromotive force of galvanic cells and the chemical processes within them was solved by Helmholtz (*Die Erhaltung der Kraft*, 1847), and later on also by Sir William Thomson (*P. M.* December, 1858), and this was done primarily on the basis of a hypothetical assumption. According to Faraday's law, when equivalent quantities of different substances are used in the galvanic cell, equal quantities of electricity are always put into motion. This being so, the intensity of the motion, or the electromotive force of the galvanic cells, must be proportional to the quantity of heat produced by the chemical processes within the cell. The supposition is made here that all heat is used for electrical work—a supposition which Thomson found verified by an experiment of Joule. Meanwhile it has been proved, however, that the heat produced in chemical changes is not generally completely transformed into electrical work, and Helmholtz (*B. B.* 1882) himself has worked out the formula representing the general relation between these two quantities.

To these problems are joined those concerning the nature and the value of galvanic polarisation. In this province investigation has, however, made so little way as yet that it suffices to point out that most important problems here await their solution.

The foundations of the science of electricity. General considerations.—If a bar of perfectly pure or amalgamated zinc is placed in dilute sulphuric acid, no chemical action takes place, nor is there any such action if a bar of platinum be introduced into the acid. But as soon as the two metals are made to touch each other an action occurs; the zinc is transformed into zinc sulphate by expelling the hydrogen from the sulphuric acid, which hydrogen, however, is evolved at the surface of the platinum bar.

Direct contact of the two metals is not necessary. If, for instance, the zinc is touched with the end of a copper wire and the platinum is touched with the other end, the same effect is produced. On the other hand, there is no effect if the connection is made through glass, wood, or such like substances.

The copper wire which connects the two metals has acquired special properties which remain as long as the chemical action of the sulphuric acid on the zinc lasts. If the wire is held parallel to a movable magnetic needle at a short distance above it, the needle will be deflected; further, the wire becomes heated; and finally, if the wire is cut in one place, and the two ends are placed close to each other on a paper moistened with solution of potassium iodide and starch, it can be perceived that a chemical decomposition of the potassium iodide has occurred, since a blue spot of iodide of starch appears under one end of the wire.

Work, or, speaking generally, *energy*, is gained by the chemical action between the zinc and the sulphuric acid; the energy usually appears in the form of heat. The arrangement described shows that it is possible to conduct this energy away from the place where it is set free—that is, from the point of contact between zinc and sulphuric acid—and to make it effective at any point of the connecting wire we please. And further, we can obtain this energy at will in the form of thermal energy, chemical energy, or mechanical energy.

The sole difference that can be perceived between the metals in their usual state and when dipped into the acid is that they have become *electric*; the platinum shows itself charged with positive, and the zinc with negative, electricity. By means of a suitable electrometer this electric charge can be measured. It appears to be dependent on the nature of the metals, as well as on that of the acid.

Hence we conclude that the chemical action between the zinc and the acid does not, as usual, give out its energy in the form of heat, but in that of electrical energy. As to whether the transformation from chemical to electrical energy is complete or partial, and, if the latter, by what this partial amount is determined, these are questions with which we can occupy ourselves only at a later stage.

As is generally the case with all forms of energy, electrical energy allows itself to be resolved into two factors, one of which is a *capacity*, and the other is an *intensity*. For these factors the general law holds, that a system can be in a state of rest only if the intensity of the energy is the same throughout the whole. An exception to this occurs only if different kinds of energy are present simultaneously in one system; then there can exist a difference of *one* intensity, if a compensation is produced by a corresponding difference of the *other* intensity.

The two factors of electrical energy are called *quantity of electricity* and *electromotive force* or *potential*; the first is the capacity, the second the intensity. In accordance with the above-mentioned law, we shall therefore say that in a system in which electrical forces alone act there is equilibrium if the electromotive force or the potential is the same throughout. This is the well-known law for conductors of electricity.

With substances which do not allow of any motion of the electricity—that is, with non-conductors—the potential can, it is true, be different in different places. But then, owing to the striving for equalisation on the part of the potential, small displacements are produced in the body, and the reacting forces of elasticity which accompany these form the compensation for the inequality of the electric intensity or potential.

When contact between two different substances occurs, a mutual action at the surface of contact is generally set up, and a displacement of energy is thus brought about. The changes in the surface-energy which thus occur seem to be generally compensated by corresponding differences in the electric intensity, *i.e.* the surfaces of different substances in contact attain different potentials. If the substances are conductors of electricity, each of them must be at a uniform potential at every point within it; hence a difference of potential exists at the surfaces of contact only.

Electrical measurements. In order to examine systematically the nature of electrical phenomena we are at the very beginning obliged to find a measure for them. We generally start from a definition of quantity of electricity, since the historical development of the science has led to the notion that this is one of the most important factors in the phenomena. And yet we have no proof that such things as the hypothetical electric fluids actually exist. What we do know of electrical phenomena are the mechanical, thermal, and chemical effects, *i.e.* the manifestations of the *electrical energy*, and it is this which is the real thing underlying the electrical phenomena. Quantity of electricity is a magnitude of the same order as perhaps a volume, and one which can be increased or decreased at will. But electrical energy cannot be destroyed, nor can it be produced; it can only be changed into, or obtained from, other forms of energy.

Electrical energy is then to be measured by the same units as other forms of energy, mechanical energy especially. The unit used for kinetic energy, which is represented by the formula $\frac{m}{2}v^2$ (where m stands for the mass, v for the velocity), is double that energy which the mass of one gram possesses when moving with the velocity of one centimetre in one second. This being so, the unit accepted for electrical energy is that quantity of energy which is obtained by the transformation of the above-defined quantity of kinetic energy into electrical energy. And further, since, as has been already mentioned, electrical energy has to be looked upon as the product of two factors, the quantity of electricity Q and the potential E, the unit by which the product QE must be measured is thus also fixed.

The units of the two factors Q and E are still arbitrary, in so far as we can choose one of them at will, that for the other being then fixed. In fact, different units have been chosen for different purposes, and accordingly different systems of electrical magnitudes have been obtained. Faraday's law, that equal quantities of electricity travel with equivalent quantities of separate ions, supplies the chemist with a natural unit for *quantity of electricity*. Hence that quantity of electricity which is combined with one gram of hydrogen as ion will serve as unit of quantity of electricity. Then the unit of potential would have to be the potential at which the above-defined quantity of electricity must be in order to produce unit of work.

This system of units has not become general;

it has been displaced by a system which is derived in a somewhat complicated manner from the action of current electricity on magnets. This system also has not been retained unchanged, but another one has been deduced from it, in which instead of the unit of length of 1 cm. a 10^9-fold value has been introduced, while instead of the unit of mass of 1 g. a value 10^{-11} times as small is accepted; the second has been retained as the unit of time. Hereby the unit of electrical energy has been changed also; it no longer coincides with the mechanical unit, but is 10^7 times greater.

In this system the unit of potential is called a *volt*; in order to get a conception of its magnitude it is to be remembered that the difference of potential at the ends of a Daniell cell is about 1·1 volt.

The unit of quantity of electricity has been called a *coulomb*. When a coulomb is forced through a volt a quantity of work equal to 10^7 mechanical units is done.

In order to fix the relations of these units to other units of energy, we must first remember that the work necessary to move 1 g. through 1 cm. against gravity is equal to 980 mechanical units, approximately. The above-defined unit of electrical energy would therefore be equal to $\frac{10^7}{980}$, or approximately to 10200 gravitation-units. Further, the unit of thermal energy is the quantity of heat which raises the temperature of 1 g. of water by 1°C., and which, according to the measurements of Joule, is equal to 42350 gravitation-units, *i.e.* 42350 g. would on falling through 1 cm. give up 1 calorie of heat, or would heat 1 g. of water by 1°C. Hence this magnitude is equal to $4·15 \times 10^7$ mechanical units. Since the unit of electrical energy amounts to 10^7 mechanical units, it follows that 1 calorie is equal to 4·15 electric energy units, or 1 volt × coulomb is equal to 0·241 calories. A number obtained more recently by Dieterici by direct measurements is probably more accurate. According to him, the energy of 1 volt × coulomb is equal to 0·2356 cal.; the unit of quantity of heat here used is $\frac{1}{100}$ of the quantity of heat given out by 1 g. of water in cooling from 100° to 0°. This factor is important for the relations between the heat produced in chemical changes and the corresponding electrical phenomena. Finally, we know from measurements by F. Kohlrausch and Lord Rayleigh that 1 g. of hydrogen as ion carries with it 96540 coulombs. The same quantity of electricity is carried by each equivalent of any other ion, for instance, by 107 g. of silver, $\frac{1}{2} \times 63·4$ g. of copper, $\frac{1}{3} \times 27$ g. of aluminium, &c.

Electric currents. If the potential of electricity is different at different places of a conductor, a movement of the electricity is produced in the same way as motion is produced in a mass capable of moving freely when it is at a higher level than its surroundings. If the difference of potential is maintained, the movement is maintained also.

The compensation of a difference in electric potential necessitates a decrease in the electric energy, which in this process changes into another form. The form most easily produced is thermal energy, but, as has been mentioned above, it is possible also to obtain mechanical or chemical work.

The measure of the quantity of energy changed into another form is given by the product of the quantity of electricity moved into the decrease of the potential. If the differences of potential are distributed over measurable distances the process is called an *electric current* The term has been taken from the analogy which in fact does exist between currents of water and currents of electricity. The level of the water corresponds to the potential of the electricity, and the quantity of water corresponds to the quantity of electricity. In both cases the transformable energy, or the available work, is equal to the product of the quantity (of electricity or of water) into the difference of level or of potential, and a current sets in when a difference of level exists. It must only be borne in mind that the phenomena which are brought about by the *kinetic energy* of the moving masses in water currents have no analogy in the domain of electricity. The electricity behaves as if it possessed only an inappreciably small velocity or mass. Therefore, when the electricity has sustained a definite decrease in potential, it has lost the whole corresponding quantity of energy, while the water can retain a part of it in the form of velocity-energy.

Electric currents are measured by their *intensity*. By this is understood the quantity of electricity which flows in the unit of time through a cross-section of the current-path; hence the intensity I has to be put as $\frac{Q}{t}$, where t stands for the time. Since electricity moves only when using energy, a loss of electrical energy corresponds to every current, the lost energy generally reappearing as heat. When heat is the only form into which electric energy is transformed, the following equation must hold; $W = EQ$, and $\frac{W}{t} = EI$, where E stands for the loss of potential between the two ends of the path of the current considered.

Experience has further shown that different conductors when introduced into a circuit cause different losses of potential along their lengths. This property has been ascribed to a *resistance* of the conductor to the motion of the electricity, in a way similar to that wherein tubes of different bore offer different resistances to the motion of water within them. In accordance with this, the resistance R is defined as the ratio between the difference of potential E and the quantity of electricity forced by means of it, in unit time, through the conductor, or, what is the same, the intensity I. Here we have $R = \frac{E}{I}$ or $I = \frac{E}{R}$. This is the celebrated law of Ohm, that the intensity or the strength of the current is equal to the ratio between electromotive force and resistance.

Combining this law with the preceding one, it follows that $\frac{W}{t} = I^2R$. This expression is the law arrived at experimentally by Joule, according to which, for currents of equal strength, the heat evolved in unit of time is proportional to the resistance, and for equal resistances it is proportional to the square of the current strength.

It is easy to deduce from the units already given the values for the units of the two new terms introduced when defining electric currents, namely, the strength of the current S and the resistance R. The unit of intensity I is that strength of current at which, in every second, one coulomb flows through the cross-section of the conductor; the unit of intensity is called an *ampère*. The unit of resistance is that resistance by means of which a current of unit intensity (1 ampère) produces in unit of time the unit of heat. As we have seen above, this last is equal to 10^7 mechanical units, or to 0·2356 calories. An attempt has been made to represent this resistance with the utmost possible accuracy, and it has been found that it equals the resistance of a column of mercury of 1 sq. mm. section and 106·3 cm. in length, at the temperature of melting ice. This unit of resistance has the name *ohm*. Slightly different to this is the *legal ohm*, which has been fixed arbitrarily as equal to the resistance of a column of mercury 106 cm. long and 1 sq. mm. section, the exact determination of the true ohm being a very difficult operation. The commercial resistances are graduated according to the legal ohm, and in scientific works in which the absolute value of the ohm comes into consideration, this difference of 3 per thousand must be taken into account. In most cases this is not necessary, just as in most cases it is immaterial whether or not a set of weights is made according to exact grams, as long as it is only made exact in its proportions.

The Law of Faraday. Those substances which allow a movement of electricity through them, *i.e. conductors* of electricity, are divided into two classes. In the cases considered so far, the assumption has been made that the only form of energy into which the electric energy of the current is transformed is heat. Conductors which undergo no change other than that they get heated when the current passes through them are called *conductors of the first class* or *metallic conductors*. To this class belong the metals, their alloys, carbon, and certain compounds.

Now, there are many substances which permit a movement of electricity through them, but in so doing themselves suffer chemical change. To these belong aqueous solutions of acids, bases, and salts, as also salts in the molten state, and a few other compounds. Such substances are called *conductors of the second class* or *electrolytes*.

The movement of electricity in electrolytes takes place in such a manner that the components of the electrolyte move independently of each other. Hydrogen, the metals, and the metallic radicles move with the positive electricity, or, according to the usual designation, from places of higher to places of lower potential. The halogens, the acid radicles, and hydroxyl, on the other hand, travel with the negative electricity, or from places of lower to places of higher potential.

According to Faraday's nomenclature the components of electrolytes—that is, on the one hand the metals, hydrogen, &c., on the other hand the halogens, the acid radicles, &c.—are called *ions*. The first named, which travel down with the current, are called *cations*, those which travel up *anions*.

In a circuit consisting exclusively of an electrolyte, a motion of electricity can take place without the corresponding chemical action being apparent. But if a conductor of the first class directly touches an electrolyte, whenever there is a movement of electricity there is also a production of the ions at the surface of contact, and the chemical effects become apparent. As proposed by Faraday, the surfaces of metallic conductors, where they touch the electrolytes, are called *electrodes*. The surface at which the anions appear is called the *anode*, and that whereat the cations appear is called the *cathode*.

Faraday also formulated the general law to which all movement of electricity in electrolytes is subject. *In every electrolyte the quantity of ion separated out is proportional to the quantity of electricity which has passed through, and the same quantity of electricity passing through different electrolytes separates quantities of the different ions that are in the ratio of the chemical equivalents of those ions.* In these propositions it has been assumed for simplicity's sake that the ions are actually separated out at the electrodes, but this is not essential for the truth of Faraday's law. The following wording completely expresses the actual meaning of Faraday's law: *Electricity can move in electrolytes only simultaneously with the ions, and so that chemically equivalent quantities of the different ions carry with them equal quantities of positive or of negative electricity.*

We arrive at a perfectly appropriate conception of the nature of electrolytic conduction if we assume that each equivalent of the different ions possesses an equally large capacity for electricity, or, to use the words of Helmholtz, 'the electricity in electrolytes behaves as if it were divided into equal atoms.'

In applying Faraday's law, it is important that we should keep in mind the difference between the equivalent and the atom; the equivalent weight is equal to the atomic weight divided by the valency. Thus the same quantity of electricity travels with 107 g. of silver, ½ × 65·5 g. of zinc, and ⅓ × 27 g. of aluminium; also with 35·5 g. of chlorine there travels only half as much electricity as with 96 g. of SO_4. As an amplification of the illustration used above, we must assign to each atom as many equal capacities for electricity as the number of valencies it possesses. Perhaps this is the path by which in the future we may arrive at an elucidation of the nature of chemical valency.

The truth of Faraday's law was tested by its discoverer himself in many ways (*Exp. Res.* vii. ser.). He convinced himself that the same quantity of dilute sulphuric acid was always decomposed by the same current, whether the electrodes, or the E.M.F., were large or small. Nor did the strength of the acid exert any influence. Finally, he introduced into the same circuit dilute sulphuric acid and tin chloride, lead chloride, or lead borate, or he led the same current through different beakers with dilute sulphuric acid, using electrodes of different metals; in all cases he found his law verified. Later on, other investigators have tested whether part of the electricity is not perhaps conducted through electrolytes in the same way as through metals, but no trace of this has been discovered; in every case the electricity passed through has been strictly proportional to the quantity of ion separated out. And the law of equivalency has also proved itself so correct that it has been used lately as a means for determining equivalent weights, and hence atomic weights.

The cases in which the same element exhibits different valencies according to circumstances are of special interest. Many such cases have been examined by Regnauld (*A. Ch.* [4] 11), who formed cells by taking platinum and different metals, along with the corresponding electrolytes, and then determined the quantities of metal dissolved when equal quantities of electricity had been allowed to pass. Thus it was found that mercury in dilute nitric acid has the equivalent 200, since it is changed into $HgNO_3$, a compound of mono-valent mercury; in a solution of potassium cyanide it has the equivalent 100, because it becomes $Hg(CN)_2$, in which the mercury is di-valent. Similarly, copper in hydrochloric acid forms $CuCl$ and has the equivalent 63·4; in nitric acid it forms $Cu(NO_3)_2$, and has the equivalent 31·7. Tin scarcely ever passes into solution except as a di-valent element; it is only in alkaline polysulphides and in a solution of caustic potash containing nitre that it acts as a tetra-valent element. Tellurium also can be made to act as a di-valent and a tetra-valent element. It is known that the elements mentioned show quite different reactions in their solutions, according as they are present as mercurous or mercuric, as stannous or stannic compounds, &c. Hence in these cases the nature of the chemical reactions depends on the quantity of electricity with which the ions are combined.

This is the place to refer back to a misunderstanding concerning the law of Faraday into which Berzelius first fell, and which has recurred many times since. As has been mentioned, Berzelius saw in this law a contradiction to his theory, and tried to refute it by the following argument: if equal quantities of electricity were required for the decomposition of equivalent quantities of the most diverse compounds, it would follow that these could be decomposed by equal forces; this, however, is not possible, since the different substances are evidently held together by quite different forces of affinity. From the illustration given above it can be seen that, contrary to the assumption of Berzelius (which, however, was very excusable, considering the state of electrical science at that time), Faraday's law does not in any way deal with *forces*, but rather with quantities of electricity. Comparing electrical decomposition to the raising of water out of wells by means of buckets, Faraday's law asserts that in spite of the differences in the depths of the wells, the size of the buckets is always the same. We would fall into an error similar to that of Berzelius if we concluded from the equal size of the buckets that the work necessary for raising the water out of all the wells of different depths was the same. The illustration also shows directly wherein the differences in chemical work, corresponding to the different depths of the wells, assert themselves, namely not in the quantities of electricity required, but in the differences of potential.

Electrolytes and ions. It follows from the nature of an electrolyte that it must be a compound substance, since otherwise its parts or ions could not transport the electricity in both directions. Yet all compounds do not possess the power of conducting electricity. In particular, we do not know of any substance liquid at the ordinary temperature which is an electrolyte; amongst pure substances it is only the salts melted at a higher temperature which conduct at all appreciably.

On the other hand, all substances having the character of salts, acids, and bases possess electric conductivity when in aqueous solution. In these cases the water exerts a specific influence, since solutions of the same substances in alcohol conduct much less if at all; and solutions in ether, carbon disulphide, and similar solvents are scarcely conductive.

There are two factors, therefore, which are necessary for the production of electric conductivity, *i.e.* the nature of the substance and the condition in which it is.

In electrolysis the molecule of the conducting compound appears to be split into two parts. There can be no doubt as to what these parts are with substances such as chloride of silver or potassium iodide; since they consist of two elements only, the metal must be one ion and the halogen the other. The question gets more doubtful with ternary compounds, such as nitric acid, sodium acetate $NaCO_2CH_3$, or ammonium chloride NH_4Cl. Since, however, no important distinction manifests itself in the behaviour of these substances and those mentioned above, it is simplest and most obvious to assume that their ions correspond to those of the substances first named. Hence the ions of nitric acid are H and NO_3, those of sodium acetate Na and CO_2CH_3, and those of ammonium chloride NH_4 and Cl.

It is possible to examine this assumption on the basis of Faraday's law. In the electrolysis of potassium sulphate as much oxygen and hydrogen are obtained as from the electrolysis of dilute sulphuric acid by means of the same current, but in addition to this there is found at the anode an equivalent quantity of free sulphuric acid, at the cathode a corresponding quantity of free caustic potash. If we assume with Berzelius that the current has decomposed the potassium sulphate into potassium oxide and sulphur trioxide, K_2O and SO_3, which combine with the water to form $2KOH$ and H_2SO_4, we should have to assume further that the same current had in the same electrolyte simultaneously decomposed an equivalent quantity of water. But this is in contradiction to the law of Faraday. If we assume, however, that the ions are K_2 and SO_4, it is comprehensible that the potassium separated out should act on the water of solution, evolving hydrogen, according to the equation $2K + 2H_2O = 2KOH + H_2$; in like manner the ion SO_4 acts on the water and forms sulphuric acid and free oxygen, according to the equation $H_2O + SO_4 = H_2SO_4 + O$. With those metals which do not decompose water, such as zinc, copper, and silver, we actually obtain the metal only at the cathode; and similarly, solutions of chlorides, bromides, and iodides do not generally give free oxygen, but free halogen.

It is necessary, therefore, to distinguish carefully between the primary and the secondary effects of electrolysis. The primary effects consist in the separation of the ions at the electrodes. But since the ions do not continue to exist as such after having given up their electricity, they undergo further changes according to circumstances. The simplest case is that of the metallic ions, when these cannot act on the water; they simply become solid or liquid metals. So also the separated atoms of the halogens pass on, combining into gaseous chlorine, Cl_2, or into the molecules of the dissolved bromine or iodine.

The metals which decompose water can still be obtained in the metallic state when water is excluded or reduced to as small a quantity as is possible. A classical example of this is furnished by the electrolysis of slightly moistened potash, by means of which H. Davy discovered potassium. The electrolysis of molten salts, that of the chlorides especially, furnishes a means for preventing the secondary reaction of the metals; such electrolyses, which had first been used by Bunsen for scientific investigations, have obtained at the present time great technical importance in the production of magnesium and aluminium.

Complex cations of the type of ammonium, NH_4, are very unstable, and until recently it was doubtful whether the so-called ammonium amalgam, which is obtained on using a mercury cathode in the electrolysis of ammonium chloride, really contained the compound radicle NH_4. By measurements of another kind (viz. of the electromotive force) the existence of ammonium in the amalgam has now been placed beyond a doubt.

The compound anions as such are all of them very unstable. Many of them, such as the anions of the nitrates, phosphates, sulphates, &c., simply act on the water by taking up from it the hydrogen required to produce acids, and liberate the oxygen. The latter, which appears in the nascent state, is capable of bringing about powerful oxidising effects. If, for instance, lead or manganese salts are electrolysed, the oxygen acts on the dissolved metal and separates it at the anode as peroxide. In other cases the anion splits up into more stable compounds. Thus in the electrolysis of formates we obtain carbon dioxide and hydrogen from the ion $HCOO$, according to the equation $2HCOO = H_2 + 2CO_2$. The acetates give carbon dioxide and ethane $2CH_3CO_2 = C_2H_6 + 2CO_2$, and similarly the salts of the higher fatty acids give the corresponding paraffins.

In some cases the secondary action can take place in another direction; in this manner the formates can produce—instead of hydrogen and carbónic acid—water, carbon dioxide, and carbon monoxide, as is shown in the following equation, $2HCO_2 = H_2O + CO + CO_2$. In most cases such secondary processes take place along with the primary actions, and the proportion between the two depends on external circumstances, temperature, concentration, current-density, &c.

In a few cases it is somewhat difficult to recognise the primary or secondary character of a product of electrolysis. On electrolysing potassium silver cyanide or sodium platinichloride, silver or platinum separates at the cathode, so that it seems as if the silver cyanide or the platinichloride were decomposed primarily. This, however, would be an erroneous view, since the ions of the salts are K and $Ag(CN)_2$, and Na_2 and $PtCl_6$ respectively, and the heavy metals are only secondarily reduced from the solutions by the alkali metals. We can convince ourselves of this by using small electrodes and strong currents, when the salt near the cathode is soon used up, and potassium (or sodium), or, more correctly, hydrogen which has been formed secondarily, separates. More distinct proof of the nature of the ions is, however, obtained by studying the migration of the ions, to be discussed later.

So far the assumption has been made that the ions exert no action on the metal of the electrode; this, however, is not always correct. Only a few metals when used as anodes offer resistance to the chemical attack of the anions. If the metal can combine with the anion it forms the corresponding salt, which either dissolves in the water of solution, or, if insoluble, remains attached to the electrode and often interrupts the current. But also when used as cathodes the metals often combine with the cation; thus mercury forms amalgams, and the hydrogen separated at the cathode is occluded in greater or smaller quantities, especially by palladium and platinum, and also by iron. In other cases the cathode simply becomes coated with a layer of the corresponding metal, which separates more or less uniformly according to its nature and that of the electrolyte. These processes are used for coating substances which are conductors, or if non-conductors, whose surfaces at least have been made conductive; such processes have also been employed for galvanoplastic coating with gold, silver, copper, &c.

The constitution of electrolytes. It has already been remarked that all compounds are not electrolytes, and that some substances which do not conduct electrolytically by themselves obtain this power when dissolved in certain solvents, especially in water. From this it follows that electrolytes have a special constitution with which their special property is connected. The question as to what this constitution is has scarcely been raised yet, much less has it been answered. This is because most of the compounds known in the days of the electrochemica system of Berzelius were electrolytes, and late on, when many organic compounds, which ar mostly non-electrolytes, were discovered, th electrochemical theory had been given up, and the interest in it had disappeared. The first investigator who proposed the question clearly —and who, as far as he could, answered it—wa Hittorf. He it was who established the proposition 'electrolytes are salts.' Under the nam of 'salt' Hittorf comprised all those compound which are capable of exchanging their constituents within the shortest time. Hence alon with the salts proper must be classed acids an bases.

By enunciating this law, Hittorf was the first to draw attention to a most important relation which has become the starting-point for the due comprehension of the constitution of electrolytes. The power to conduct electricity and the power to exert chemical reactions are so closely parallel that both must be considered as the outcome of the same cause. This cause, however, has to be looked for in the constitution of the electrolytes themselves.

Electrolytic conduction is brought about by the positive and negative electricities moving through the conductor bound to their ponderable carriers, the ions; it is necessary, therefore, to assume a considerable mobility of the ions.

And, further, electrolytic conduction occurs in consequence of any difference in potential, however small. It is necessary, therefore, as was already pointed out by Clausius (*P.* 101, 338), that in every electrolyte there should be present a certain number of ions capable of moving freely, *i.e.* in every electrolyte a portion of the salt-like compound which produces the conduction *must be partly split up into ions.* Clausius left undecided how great this portion is, as he possessed no means to determine it. To the chemists who, in consequence of a peculiar shifting of judgment, considered electrolytes generally as specially stable compounds, he made the concession that this portion might be very small. In the imagery of the kinetic hypothesis he conceived that, owing to the collision of the molecules of the electrolyte with each other and with those of the solvent, one or other occasionally splits into its constituents, and so gives the necessary free ions.

It is now possible to urge similar considerations from the chemical side. While gaseous substances at the ordinary temperature react but seldom, acids, bases, and salts dissolved in water do so instantaneously. A mixture of oxygen and hydrogen does not form water until it has been heated to between 400° and 500°; a mixture of hydrochloric acid and potash, however, when in aqueous solution, passes so quickly into potassium chloride that it has been found impossible as yet to determine the time required for the change, and yet in the first case 68,000 cal. of heat are produced, while in the second the heat produced, or the energy liberated, is only 13,700 cal.—that is, five times less. In general, non-electrolytic solutions also react with each other extremely slowly. An example of this is afforded by the means which must be taken to hasten the reactions of non-electrolytes, and especially of organic compounds; this has to be done by heating the reacting mixtures, often under increased pressure. For the formation of acetic ether from a mixture of alcohol and acetic acid—that is, for a process intimately connected with that of the formation of salts—at least ten years are needed, at the temperature of the room, before it has approximately attained the end which under these conditions it can reach. From the chemical point of view, therefore, it is necessary to suppose that compounds which react instantaneously—that is, electrolytes—possess a special mobility of their parts or ions; and that it is the constituents of 'salts'—the term being used in the widest sense—which are the ultimate causes of electrolyses as well as of chemical reactions. These constituents of salts are, on the one hand, the metals, the metallic radicles, and hydrogen; on the other hand, the halogens, the acid radicles, and hydroxyl. It is possible, therefore, to apply to substances which react rapidly—that is, to salts, as this term was used by Hittorf—the same kinetic considerations as were made use of by Clausius to show the presence of ions in electrolytes.

We are now confronted on both sides by the question of how great is the proportion of free ions, or of decomposed molecules, in solution of electrolytes. The fact that a maximum reacting power exists for a given class of substances is in contradiction to the assumption that this proportion is inappreciably small. It has already been explained (compare the article AFFINITY) how the substances which have been most carefully examined from this point of view—the acids—exert their chemical reactions according to a definite co-efficient which is characteristic of each acid. This co-efficient—which can be determined, for instance, by means of the velocity of inversion of cane sugar—cannot be increased at will, and does not exceed a definite maximum value, which maximum is possessed by hydrochloric acid, nitric acid, benzenesulphonic acid, &c. All the conditions—such, for instance, as the introduction of oxygen, sulphur, or halogen into the molecule—which increase the velocity of reaction of weak acids are without any measurable effect on the strongest acids. From this it follows that the circumstance which is the cause of the velocity of reaction—that is, the unimpeded mobility of the ions—has in these substances already reached its highest degree, or is at least very near to it, since, in opposition to Clausius and to the views current till now, we must assume that in aqueous solutions of these strong acids it is not, perhaps, a few hundredths or thousandths of the molecules present which are split into their ions, *but rather that by far the greater part of the electrolyte is split into ions.*

A similar conclusion can be drawn from the degree in which electrolytes conduct the current. The more detailed consideration of this subject will be taken up presently. Here it will only be mentioned that the results of these investigations agree completely with those on the velocities of reactions.

A third entirely independent verification of the unexpected conclusion that aqueous solutions of the strong acids are nearly completely dissociated can be gained from a study of the properties of these solutions.

Only so much of van't Hoff's theory of solutions (*Z. P. C.* 1, 481) as is necessary for understanding the constitution of electrolytes will be explained here.

The fundamental idea of van't Hoff's theory is as follows. The physical properties of gases, and especially the relations between pressure, volume, and temperature, are practically independent of the special nature of the substance, while such an independence does not exist with liquid and solid substances. The cause of this phenomenon may be sought in the fact that the smallest parts or molecules of gases are always at such a distance apart that they are not capable of exerting an action on each other. In liquid and solid substances, however, the molecules are in close proximity, and exert, therefore, their specific reciprocal actions. But there is another condition in which the molecules of a substance are relatively distant from each other, namely, when the substance is present in a solvent in the state of a dilute solution.

We should expect, therefore, that in this state matter would be subject to laws analogous to those which hold for gases.

The first property characteristic of gases is their power of extending uniformly through any given space. Solutions exhibit the same peculiarity. When the pure solvent is placed over the solution of any substance, the substance begins directly to enter into the solvent (the pure solvent playing the part of a vacuum), and the movement does not cease until, as with gases, the substance is uniformly distributed through the whole space. The only apparent difference is that in the case of gases this process is completed in a very short time, while with solutions months, and even years, are needed in order to bring it, practically speaking, to an end. This movement can be impeded by introducing between the solution and the pure solvent a partition which allows the passage of the latter but not of the former. Such a 'semi-permeable' partition can be produced by saturating a porous clay cell, for instance, with a solution of copper sulphate, washing the cell, and filling it with a solution of potassium ferrocyanide. A pp. of amorphous copper ferrocyanide is thus formed in the pores of the clay, and this pp. allows the passage of water through it, but does not allow various other substances to pass. In order to arrive at a conception of the cause of such a property we can imagine that the pp. of copper ferrocyanide acts as a filter which allows the passage of the smaller water molecules, while it retains the larger molecules of the dissolved substance.

W. Pfeffer, who has studied such cells very thoroughly, found that if the cells are closed a very considerable amount of pressure is produced in their interior. A 1 p.c. solution of sugar produces a pressure of more than 50 cm. of mercury; a solution of nitre of equal strength gives pressures of between three and four atmospheres. Pfeffer also found that the pressures increased, at constant temperature, to maximum values, which remained constant as long as the partition remained intact. These pressures proved to be proportional to the concentrations, and further, they increased with a rise of temperature.

According to van't Hoff, this pressure, the 'osmotic pressure,' is to be looked on as analogous to the gaseous pressure. It is possible to form a similar conception of its cause as is formed of the cause of gaseous pressure; the molecules of liquids, like the molecules of gases, possess a quantity of kinetic energy which is proportional to the temperature. The solvent—for instance, the water—can pass through the semi-permeable wall, and since it is present on both sides its pressure is the same on both. The substance dissolved, however, bombards the wall from one side only, and thus a pressure is set up. This view—which, however, is only hypothetical, and which can be accepted or rejected without the theory itself being called in question—has been objected to on the ground that if it were true a weak-walled vessel must needs be broken by a solution placed in it. But this assertion overlooks the important point that the osmotic pressure can exert itself only *within* the solution. If we imagine for simplicity's sake a drop of a solution floating in space, it is true that a pressure due to the substance dissolved will be exerted on the internal surface of the drop, which pressure may easily amount to 100 atmospheres. But to this pressure there is opposed the normal capillary pressure of the liquid, the magnitude of which we do not yet know very exactly, but of which we can assert that it has to be measured by thousands of atmospheres (in the case of water it is approximately 20,000 atmospheres). Hence this pressure is under all circumstances quite sufficient to maintain equilibrium with the osmotic pressure, and the only effect of the latter is to slightly increase the volume of the solution.

It has been shown by van't Hoff that the laws of osmotic pressure exactly coincide with those of gases. Boyle's law enunciates that pressure and volume are inversely proportional. Pfeffer's law says that pressure and concentration (or density) are proportional; this agrees with Boyle's law. Further, the law of Gay-Lussac tells us that at constant volume (or at constant density) the pressure of a gas increases with the temperature, and that for each degree it does so by $\frac{1}{273}$ of the value at 0°. A similar thing has been proved by van't Hoff from the numbers obtained by Pfeffer. And finally for gases we have the law of Avogadro, that, temperature and volume being the same, equimolecular quantities of different gases exert the same pressure. Taking the molecular weights in grams, and taking for the common volume 1 litre, then at 0° this pressure is equal to 22·37 atmospheres. Now, it has been observed by Pfeffer that the osmotic pressure of a one per cent. solution of cane sugar, which therefore contains 10 g. in one litre, is 0·649 atmospheres at 0°. The molecular weight of sugar $C_{12}H_{22}O_{11}$ is 342; a solution containing this quantity in grams in one litre would exert a pressure $\frac{342}{10}$ times as great—that is, a pressure of 22·2 atmospheres. This number agrees within the limits of experimental error with that which holds good for gases; and hence Avogadro's law holds also for solutions, or, more correctly, so far, for solutions of cane sugar.

The question whether the law holds for other dissolved substances must be answered in the affirmative. It is true that only very few measurements of osmotic pressures have been made, but these phenomena are so closely connected with others to be considered shortly, that it has been possible to place the general validity of the law beyond doubt.

Let us imagine a solution poured into a vessel of the form of an inverted funnel, the opening of which is closed by a semi-permeable wall in contact with which is a quantity of the pure solvent. Then the solution will rise in the tube, because of the greater internal pressure, and equilibrium will be established only when the pressure of the liquid column in the tube has become equal to the osmotic pressure. Let this arrangement be covered by a bell-jar, from which the air has been completely expelled; the solution will then be surrounded by the vapour of the solvent only. But the pressure of the vapour is slightly smaller in the upper part of the bell-jar, at the level of the solution, than below at the level of the pure solvent, and it is smaller by an amount which is equal to the pressure of the weight of the vapour present between the two levels. Moreover, it is by this amount that the vapour-pressure of the solution must fall short of that of the solvent, because, if this were not the case, liquid would either continually evaporate, or condense, at the surface of the solution;

in consequence of the osmotic pressure, the changes in level produced would always equalise themselves again, and we should have a *perpetuum mobile*, which is impossible.

It follows, therefore, that in general the vapour-pressure of a liquid must decrease when a substance is dissolved in it, and that this takes place according to laws which run parallel with those of osmotic pressure.

This theoretical conclusion is in accordance with observation. It has been found by Wüllner (*P.* 103, 529) that, at a constant temperature, the decrease of the vapour-pressure of an aqueous solution is proportional to the concentration of the solution. Babo on his part had established that the ratio between the vapour-pressures of the pure solvent and the solution is independent of the temperature. Both results have been confirmed, on the whole, by later investigations. Raoult especially has occupied himself with this question; he has shown that this behaviour is general, and he has also found that equimolecular weights of different substances dissolved in the same solvent produce equal diminutions of the vapour-pressure, and finally that on using equimolecular quantities of different solvents the relative diminution in the vapour-pressures is the same. If f stands for the vapour-pressure of the solvent, f' for that of the solution, and if further N stands for the number of molecules of the solvent (in gram-units), n for the number of molecules of the substance dissolved, the general expression holds

$$\frac{f-f'}{f}=\frac{n}{\mathrm{N}+n}.$$

While Raoult discovered this law empirically, van't Hoff has deduced it theoretically from the laws of osmotic pressure (*Z. P. C.* 1, 494).

This formula can be used for determining the molecular weight of a substance in solution. Let p grams of a substance with unknown molecular weight m be contained in 100 g. of the solvent, the molecular weight of which is M; then $\frac{p}{100}\mathrm{M}$ = grams of substance dissolved in one molecular weight of the solvent; let this $=s$; then putting $n=\frac{s}{m}$, and $\mathrm{N}=1$, and solving the equation for m, it follows that $m=\frac{sf'}{f-f'}$.

Finally, a third set of phenomena is known, governed by similar laws. It has long been known that salt water freezes at a lower temperature than pure water. As far back as 1788 Blagden (*T.* 1788) established the fact that the lowering of the freezing-point of a solution of salt in water is proportional to the amount of salt dissolved. Later on, Rudorff (*P.* 114, 63) rediscovered this fact, which had been forgotten, and de Coppet found that equimolecular solutions of salts having analogous constitutions exhibited equal lowerings of the freezing-points (*A. Ch.* [4] 23, 366). Raoult discovered that the same law held for the most diverse solvents. This law states that equimolecular quantities of whatever substances we take, added to a constant quantity of the solvent, lower the freezing-point by the same amount (*C. R.* 1882). Raoult thought for a time that the lowering of freezing-point was the same for equimolecular quantities of different solvents, but this proved to be erroneous. Van't Hoff has deduced this important relation from the laws of osmotic pressure, and his formula agrees well with experiment (*Z. P. C.* 1, 481).

We can convince ourselves of the necessity of these relations by an argument similar to that used in order to prove the connection between osmotic pressure and change of vapour-pressure. As the mechanical theory of heat tells us, below 0° the vapour-pressure of ice decreases more rapidly than that of over-cooled water. A temperature must therefore exist whereat a salt-solution, which has a vapour-pressure less than that of water, exhibits the same vapour-pressure as ice. This is the only temperature at which the solution can exist side by side with ice, as otherwise a *perpetuum mobile* would be possible. Since, therefore, this temperature, which is the freezing-point of the solution, is in inseparable connection with its vapour-pressure, the laws holding for the one must also hold for the other, and from this the laws already stated follow directly. Formulating these laws, we get $\Delta=r\frac{p}{ml}$ where Δ is the lowering of the freezing-point, l the weight of the solvent, p that of the substance dissolved, and m the molecular weight of the substance, while r is a constant dependent on the nature of the liquid. From the formula it follows: $m=\frac{rp}{\Delta l}$. Having, therefore, once for all determined the constant for a solvent, it is possible to find the molecular weight of a substance by determining the lowering of the freezing-point of its solution in that solvent. Van't Hoff has shown that the constant can be deduced thermo-dynamically from the heat of fusion of the substance.

If we now apply these methods for determining the molecular weights of dissolved substances to solutions of electrolytes, we find that the molecular weights appear smaller, and hence the number of molecules in solution are greater, than correspond with the formulæ. In many cases the amount of this deviation is very considerable, and its existence at first proved a great obstacle in the way of van't Hoff's theory of solutions. To Arrhenius (*Z. P. C.* 1) we owe the means of accounting for the deviation. The views propounded by this investigator have shed such a flood of light over difficult questions in chemistry and physics that we must consider the work of Arrhenius to be one of the most important advances ever made in this and in allied domains.

Arrhenius' idea consists in ascribing the deviations of the observed from the calculated molecular weights, to a dissociation of the electrolytes into their ions. From the magnitude of this deviation a conclusion can be drawn as to the number of molecules which are dissociated; the problem which was left unsolved by Clausius thus receives its solution.

Reserving the numerical proofs of the truth of this view till later on, it is proposed to deal first with some possible objections and difficulties of a general nature.

The application of the hypothesis leads to the conclusion that in moderately dilute solutions of strong acids and bases, and also of normal salts, as much as 80 to 90 per cent. of the substance in solution is dissociated into its ions. Hence a solution of potassium chloride contains little else than ions of chlorine and potassium. How is it that the chlorine does not escape into the air as a greenish yellow gas, and the potassium does not act on the water?

The answer lies in the consideration that the chlorine which we know as a greenish yellow gas is the electrically neutral molecule Cl_2, and does not consist of the separate atoms of Cl which are charged with a large amount of negative electricity.[1] The potassium again is not present as the compact metal, but in the form of strongly positively charged ions. Considering the great differences exhibited by allotropic forms of the same element (oxygen and ozone, red and yellow phosphorus, &c.), we cannot wonder that in these cases also considerable differences appear.

And it is further possible to produce solutions in which such ions—as, for instance, potassium—are present in excess, and therefore certainly in the free state. For this purpose, let us imagine two vessels filled with potassium chloride solution and placed on an insulating stand, and then connected conductively by means of a syphon filled with the solution. Let us now bring near to the one vessel a body charged with negative electricity. The vessel becomes charged positively by induction, and an equivalent quantity of negative electricity moves through the syphon into the second vessel. If we now remove the syphon, and then the body charged, the first vessel remains charged positively, the second vessel negatively. So far the experiment contains nothing that is new; it is the elementary experiment used for proving the inductive effect of electricity. If, however, we pay attention to the fact that, according to the law of Faraday, electricity can move in electrolytes only simultaneously with the ions, the conclusion is inevitable that an excess of potassium ions must be present in the vessel charged positively, and the same excess of chlorine ions must be present in the vessel charged negatively. These excesses of ions are maintained as long as the electric charge of the vessels exists. On discharging the vessels the ions give up their electricity, and the substances appear at the point of discharge endowed with their usual properties.

Owing to the magnitude of the quantities of electricity contained in the ions, the question may be raised whether the experiment which has just been indicated really can be carried out. Ostwald and Nernst have shown (*Z. P. C.* 3) that this is actually possible. By means of a mercury electrode contained in a capillary tube, such small quantities of hydrogen can be observed that the experiment becomes quite feasible. Since under ordinary conditions one gram of hydrogen occupies a space of about 12,000 c.c., a small bubble of 0·1 mm. diameter, which one can still see with the naked eye, has a weight of only 10^{-10} g., and one of 0·01 mm. diameter, which can be seen under a microscope, has a weight of only 10^{-13} g. This is as small a quantity of matter as can be recognised in any way, and the electricity combined with it can be detected in an apparatus of very moderate dimensions.

Thus the experiment described above is not only conceivable, but feasible; and thus it is proved that free ions, such as those of potassium, can be present in aqueous solutions without acting on the water.

The assumption that some of the molecules of electrolytes are split into ions in solutions explains many properties of these solutions. In the following paragraph we will assume for simplicity's sake that the splitting up is complete—an assumption which is nearly correct in the cases of salts, strong acids, and bases; the modifications which must be introduced into these considerations by taking into account the portions not split up, will be considered afterwards.

Let us consider, first, the chemical reactions of electrolytes. As is well known, certain reactions are used in analytical chemistry for indicating definite substances. These reactions must take place quickly, as otherwise they would be of no practical use; hence they must be reactions between ions. If asked what it is that the ordinary analytical reactions allow us to recognise, we are inclined to answer, the different chemical elements. But this is not at all appropriate. A solution of a salt of silver is called a reagent for chlorine, and in fact by its help chlorine can be detected in metallic chlorides. But the chlorine in potassium chlorate or in monochloracetic acid cannot be detected by means of silver solution. In the same way chlorides indicate silver; but the silver in potassium silver cyanide cannot be recognised by means of chlorides. The different oxyacids of sulphur also give quite different reactions, though they all contain the same elements; similarly, the reactions of iron, copper, mercury, tin, &c., are quite different, according to the degree of oxidation of the metal.

These examples prove that it is not the elements which are indicated by analytical reactions. A more careful consideration shows that since it is the ions which react, the ions are indicated by the analytical tests.

This simple proposition removes all the difficulties which confronted us. If a solution of silver is a reagent for chlorine ions, naturally it cannot indicate the chlorine in potassium chlorate, whose ions are K and ClO_3; nor in monochloracetic acid, whose ions are H and CH_2ClCO_2. And, conversely, silver is indicated by chlorides only where it appears as the ion; but the ions of potassium silver cyanide are K and $Ag(CN)_2$. The behaviour of chloroplatinic acid H_2PtCl_6 towards silver solutions is specially remarkable, a behaviour about which an incredible confusion has reigned in chemistry, because it has always been believed that its chlorine must be precipitated by silver solution as silver chloride. The matter was first cleared up by Jörgensen (*J. pr.* [2] 16), who found that no silver chloride is formed at all, but rather the silver salt of chloroplatinic acid Ag_2PtCl_6; sodium platinichloride is completely precipitated by two equivalents of silver solution only, instead of by six, which correspond to the proportion of chlorine.

---

[1] From the number, already given, of 96,540 coulombs, which are combined with 1 g. of hydrogen and which are also present in one litre of normal potassium chloride solution—as positive electricity on the potassium, or negative electricity on the chlorine—it is possible to calculate that this quantity of electricity would suffice to charge a sphere of an approximate diameter of 10^{16} cm.—which, therefore, would be larger than the whole solar system—to a potential of one volt.

Thus the so-called anomalies of analytical reactions are fully explained. It is further explained why, for instance, all the different sulphates give the same reaction with barium chloride. The nature of the metal is of no account, because the reacting ion SO_4 is not combined with the metal at all, but exists by itself.

It is a remarkable fact that similarly constituted ions give, under certain conditions, different reactions. According to this view, the iron in a solution of $FeCl_2$, and also in a solution of $FeCl_3$, is contained as an ion; yet the two act differently. In like manner, solutions of $K_4Fe(CN)_6$, as well as those of $K_3Fe(CN)_6$, contain the same negative ion $Fe(CN)_6$, and these two substances give quite different reactions. The explanation lies in recognising that these similarly composed ions are endowed with different quantities of electricity according to their valency. Thus iron appears divalent and trivalent, mercury and copper monovalent and divalent, the atomic group $Fe(CN)_6$ tetravalent and trivalent, in that they contain corresponding numbers of positive or negative electric units or 'atoms.'

If the theory developed so far is correct, then all properties of salt solutions must be of an *additive* nature with regard to the two ions—*i.e.* their properties must be made up of two parts, one of which depends only on the positive ion, and the other only on the negative ion. This fact was recognised before it found an explanation in terms of the hypothesis of the independent existence of ions in solutions. Arrhenius drew attention to this fact (*Z. P. C.* 1) when he was establishing his theory. Some examples will make the point clearer.

In 1874 Valson enunciated a law concerning the specific gravities of salt solutions (*C. R.* 73), which he called the *law of the moduli*. By means of it the specific gravity of a 'normal' solution—that is, of a solution containing one equivalent of the salt in grams in one litre—of any salt can be found by adding to the specific gravity of a solution of ammonium chloride (chosen as the standard) two values, one of which depends on the metal only, and the other on the acid radicle only. According to Valson, these moduli are (NH_4ClAq of specific gravity 1015 being taken as the standard);—$K = 30$, $Na = 25$, $\frac{1}{2}Ca = 26$, $\frac{1}{2}Mg = 20$, $\frac{1}{2}Sr = 55$, $\frac{1}{2}Ba = 73$, $\frac{1}{2}Mn = 37$, $\frac{1}{2}Fe = 37$, $\frac{1}{2}Zn = 41$, $\frac{1}{2}Cu = 42$, $\frac{1}{2}Cr = 61$, $\frac{1}{2}Pb = 103$, $Ag = 105$; $Br = 34$, $I = 64$, $\frac{1}{2}SO_4 = 20$, $NO_3 = 15$, $\frac{1}{2}CO_3 = 14$, $HCO_2 = 16$. To these are added the value zero for NH_4 and Cl. These values allow us to calculate the specific gravities of solutions of 14 × 7 = 98 salts, and the calculations agree very well with experiment. Later on (1883), the law was confirmed by C. Bender (*W.* 20, 560), and by Nicol (*P. M.* [5] 18, 179), and was also extended by the first named.

A similar law was established by Gladstone (*Pr.* 16, 439) for the refraction-equivalents of salts. Gladstone expressed his generalisation in the form that the difference between the refraction-equivalents of the salts of two metals with the same acid is always the same, and is independent of the composition of the acid. The following table shows how the values agree in the cases of salts of potassium and sodium with acids of different compositions:—

	Potassium	Sodium	Difference
Chloride	18·44	15·11	3·3
Bromide	25·34	21·70	3·6
Iodide	35·33	31·59	3·7
Nitrate	21·80	18·66	3·1
Hydrate	12·82	9·21	3·6
Alcoholate	27·68	24·28	3·4
Formate	19·93	16·03	3·9
Acetate	27·65	24·03	3·6
Tartrate	57·60	50·39	3·6
Carbonate	34·93	28·55	2 × 3·2
Bichromate	79·9	72·9	2 × 3·5
Hypophosphite	26·94	20·93	2 × 3·0

A similar law exists for the salts of strong acids, but with the weak acids the differences are much greater. We are now in a position to account for this discrepancy, which was left unexplained by Gladstone. Since the weak acids are only very partially split into their ions, it cannot be expected that hydrogen as an ion should have the same refraction-equivalent as it has in the undecomposed compound.

Gladstone also enunciated the general law that the colour of the solutions of salts whose acid or whose metal form coloured compounds is independent of that of the other constituent (*P. M.* [4] 14, 418). If we consider how dependent colour is on constitution in other cases, this fact must be considered as a specially weighty proof of the mutual independence of the ions.

The knowledge of the fact that the characteristic colours of salts are dependent on the nature of the coloured ion only, and are independent of that of the other ion, has existed for a very long time, almost, as one might say, unconsciously. In green liquids we should always expect nickel, in red ones cobalt, in pale blue ones copper, &c. Some exceptions to this can easily be explained. One such exception is that most copper salts show the blue colour of the copper ions, while concentrated solutions of copper chloride appear green. The cause of this is that in concentrated solutions a considerable number of *undecomposed* molecules $CuCl_2$ are present, which molecules are coloured a deep yellow, as can be seen in dry copper chloride, which looks almost reddish brown. This yellow colour mixes with the blue colour of the copper ions, and produces the green colouration. From the fact that as the temperature is raised the green colour becomes more intense, it must be concluded that with rise of temperature more molecules $CuCl_2$ form at the cost of the ions (*v.* Ostwald, *Z. P. C.* 9, 579).

Another additive property has been found by Marignac (*A. Ch.* [5] 8, 410) in the specific heats of salt solutions. This property is, however, partly hidden by small deviations which, though capable of explanation, require the knowledge of some quantities the measurement of which has not yet been undertaken.

And, further, Ostwald (*J. pr.* [2] 18, 353) has proved such relations to hold in a fairly extensive manner for the volume-changes accompanying neutralisation. On saturating solutions of potash, soda, and ammonia by the same acid the total volume changes in a very different manner. These volume-changes are, however, governed by the law that on saturating two bases by the same acid the difference of the volume-changes is independent of the nature of the acid; and in like manner the difference in the volume-change on saturating two different acids by the same base is uninfluenced by the nature of the base. Hence the volume-change always depends on two constants, one of which is determined by the acid only, and the other by the base only; the specific nature of the salt formed has no influence. The following table shows these relations:—

	Potassium	Sodium	Ammonia
Nitric acid . .	20·0	19·8	− 6·4
Hydrochloric acid .	19·5	19·2	− 6·6
Hydrobromic acid .	19·6	19·3	− 6·6
Hydriodic acid .	19·8	19·6	− 6·4
Formic acid . .	12·4	12·1	−13·6
Acetic acid . .	9·5	9·3	−16·3
Monochloracetic acid	10·9	10·6	−15·1
Dichloracetic acid .	13·0	12·7	−13·0
Trichloracetic acid.	17·4	17·1	− 8·7
Isopropionic acid .	7·8	7·7	−17·8
Butyric acid . .	7·0	6·8	−18·6
Isobutyric acid .	6·3	6·1	−19·3
Glycollic acid. .	9·6	9·8	−16·5
Lactic acid . .	8·3	8·1	−17·7
Sulphuric acid .	11·9	11·5	−14·4
Oxalic acid . .	9·9	9·7	−16·1
Succinic acid. .	8·2	7·9	−17·6
Malic acid . .	8·6	8·5	−17·4
Tartaric acid. .	9·4	9·2	−17·0

The differences between the corresponding members of two horizontal or of two vertical columns in this table are seen to be constant within the limits of error. The all but complete equality of the values for the four first-named acids, which are almost completely split up into their ions, is remarkable.

The most striking case of the additive properties of salt solutions is, however, given by their thermal relations. Hess long ago established the law of the thermo-neutrality of salts; this law declares that there is no thermal effect on mixing the solutions of two salts provided that everything remains in solution. This fact is difficult to understand as long as we assume the existence in an undecomposed state of normal salts in solutions, since the mutual changes of the salts would have to proceed without any energy-change, and this is a behaviour without analogy. If we assume, however, that the solutions of the salts contain chiefly the ions of the salts, the fact becomes explicable, because on mixing the solutions, the ions remain unchanged, they do not influence each other, and hence there is nothing to cause thermal effects.

More remarkable still is the explanation which the theory gives concerning the heats of neutralisation of acids and bases. At first sight it seems as if no action could take place between such compounds, if we consider the strong acids and bases to be almost wholly separated into ions. Because if the solution of the acid, of the base, and of the salt contains ions only, no change ought to occur when the acid and the base are mixed. If, however, we consider the reaction more carefully, we arrive at different results. For instance, let there be given soda and hydrochloric acid; the reaction will be

$$\overset{+}{Na} + \overset{-}{OH} + \overset{+}{H} + \overset{-}{Cl} = \overset{+}{Na} + \overset{-}{Cl} + H_2O$$

The ions sodium and chlorine remain unchanged; but since water conducts very badly, only a very slight separation of H_2O into the ions OH and H can occur, hence when the ions OH and H meet they must combine to form H_2O.

Hence the process of neutralisation in aqueous solutions is not a combination of the constituents of the salt, but only a combination of the constituents of water.

It is true that this remarkable result is somewhat contradictory of the usual views on the subject, but it is in complete agreement with the facts. If the process of neutralisation between acids and bases decomposed into their ions really consists only in a formation of water from hydrogen and hydroxyl, then *its concomitant phenomena must be independent of the nature of the acids and the bases.*

The most important of these concomitant phenomena is the heat of neutralisation. This value has been determined by different observers, with special exactness by Thomsen (*Th.* 1). A number of measurements are collected in the following table, calculated for one equivalent; the unit used is the rational calorie, K = 100 gram-units of heat:—

	NaOH	KOH	LiOH	½BaO_2H_2	½CaO_2H_2
HCl. .	137	137	137	139	139
HBr .	137	137	—	—	—
HI . .	137	136	—	—	—
HNO_3 .	137	138	—	140	139
$HClO_3$.	138	138	—	140	—
$HBrO_3$.	138	138	—	—	—
HIO_3 .	138	138	—	—	—
$HClO_4$.	141	143	—	—	—
½$H_2S_2O_6$.	135	—	—	139	—
½H_2PtCl_6 .	136	—	—	—	—

And, similarly, tetramethylammonium hydroxide, platinodiamine hydroxide, and triethylsulphine hydroxide give with hydrochloric acid 138, 137, and 137 K respectively.

From this table, which could easily be enlarged, it follows that the heat of neutralisation of the strong acids and bases is a constant, and is approximately equal to 13,700 cal. This number must be looked on as very nearly equal to the heat of formation of water from the ions $\overset{+}{H}$ and $\overset{-}{OH}$. (A more exact calculation gives 13,500 cal.) The small deviations which are still present originate in the fact that the splitting up of the acids and bases referred to, though very considerable, is yet not quite complete; it is in this undecomposed remnant that the individual nature of the two substances still asserts itself a little.

The conditions become quite changed when we consider the weak acids and bases. Here the constancy of the heat of neutralisation ceases completely, and values are observed which fluctuate between 163K and 10K. In these cases the quantities of heat which are concerned in the splitting up of the acid and the base into their ions must be taken into account, besides the heat of formation of water from its ions, and the heat of neutralisation may be represented by an expression of the form $N = 13{,}500 + A + B$, where $A + B$ is the quantity of heat necessary for decomposing the acid and the base into ions. As experiment has shown that the salts when in dilute solution are uniformly and nearly completely decomposed, their heats of decomposition need not be taken into account meanwhile. This formula also expresses a law which, discovered some time back by Favre and Silbermann (*A. Ch.* [3] 37, 486), has been confirmed by the younger school of thermo-chemists. This law is, that the difference between the heats of neutralisation of any two bases is always the same whatever acid is taken, and that likewise the difference between the heats of neutralisation of any two acids is independent of the base. This is only another expression for the proposition that the acid and the base each contributes towards the heat of neutralisation a definite portion, which is independent of the nature of the substance with which the acid or the base reacts.

Very similar facts may be noticed concerning the other phenomena which accompany neutralisation. A table has already been given (p. 189) showing that the same relations hold good for the changes of volume that accompany neutralisation; the strong acids and bases give, on neutralisation, very nearly the same change of volume, *i.e.* 20 c.c. per litre of normal solutions of acid and base. The same holds good for the changes in the refractive indices.

The electrical conductivity of electrolytes.—Ohm's law $I = \frac{E}{R}$ gives a definition of R, the resistance of a conductor. It has been shown that the resistance is dependent on the nature of the conductor, and on its dimensions, in that it varies directly as the length and inversely as the cross-section. It has been agreed to call the resistance of a conductor of cross-section 1 sq. millim. and length 100 centim. its *specific* resistance; this depends on the nature of the material of which the conductor consists, and on its temperature.

If we define a quantity $C = \frac{1}{R}$, and call it the *conductivity*, Ohm's formula becomes $I = EC$. We may best regard C as the power of the conductor to allow the electricity to pass through, or the power to transport the electricity. In the illustration of a current of water in a tube, C would be comparable to the cross-section of the tube. The conductivity is the reciprocal of the resistance. In calculating the strength of currents it is more convenient to work with resistances; if these are connected end to end, the total resistance is the sum of the individual resistances; but if the resistances are connected side by side, the conductivities must be summed up. For electro-chemical purposes the idea of conductivity has always proved more useful than that of resistance.

Measurements of resistances or of conductivities are made according to different methods, all of which rest on the application of the formula above given. For instance, we can measure the current strength, I, using the same electromotive force E (from a constant cell, as, for instance, a Daniell), there being included in the circuit at one time the resistance R, which is to be determined, and at another time a resistance of known magnitude R_0. We then get the equations $I_1 = \frac{E}{R_1}$ and $I_0 = \frac{E}{R_0}$, and from these $R_1 = R_0\frac{I_1}{I_0}$. It is not necessary to discuss here the various methods of measuring resistances.

As mentioned before, the unit of resistance used is the *ohm*—*i.e.* the resistance of a mercury column of 1 sq. mm. section, and 106 or 106·3 cm. length at 0°. The unit of conductivity is given by the same quantity; since this represents the reciprocal value of the resistance, it has been proposed to designate it by Mho, which is the name Ohm reversed, and for which Mo might be put shortly.

While so far the different powers for conducting electricity possessed by the metals have remained more a question of practical than of theoretical importance, the study of the electrical conductivity of electrolytes has led to most important and suggestive views as to their nature. These have only been arrived at quite lately, chiefly because until recently there existed no convenient and good method for determining the conductivities of electrolytes in solution.

The difficulty to be surmounted consists in the fact that the current must be conducted through the electrolyte by means of electrodes, and that these get coated with the ions which separate—*i.e.* they become *polarised*. In consequence of this the electrodes become the seat of new electromotive forces, the magnitude of which is variable, and therefore not capable of being determined exactly. One method only has been brought forward as yet in which this difficulty is completely obviated; it is due to Guthrie and Boys (*P. M.* 1880. 328), and consists in allowing a system of strong magnets to rotate rapidly round the axis of a cylindrical vessel filled with the electrolyte and suspended by a long thin wire. By this means currents are produced in the electrolyte (as would be produced in every conductor), the electrodynamic effect of which tends to rotate the vessel in the same direction. The strength of these currents is proportional to the conductivity of the liquid, and the vessel is rotated until the torsion of the suspending wire becomes sufficient to maintain equilibrium against this rotatory effect. We are therefore justified in putting the deviation as proportional to the conductivity, the velocity of the magnets remaining the same. As the currents produced in the electrolyte occur exclusively within it, no polarisation is possible. The method has not been applied, because the apparatus required is expensive and difficult to handle.

Becquerel and Horsford tried to bring up polarisation to its highest value by using strong currents. In this method the current is led through the electrolyte, then through an adjustable resistance, and finally through an instrument for measuring currents (galvanometer, &c.), and its strength is determined. The distance between the electrodes is next decreased by an accurately measured amount, and resistances are inserted until the strength of the current has regained its value; then the resistance inserted is equal to that possessed by the portion of the liquid taken out. The method suffers from the disadvantage that it is difficult to keep the electromotive force of polarisation constant as presupposed; and, further, the liquid is changed at the electrodes by the use of the stronger currents required, so that what we measure is the resistance of the changed, and not that of the original, liquid.

By using electrodes of zinc, which in solutions of zinc salts give no polarisation, Beetz (*P.* 117, 1) was able to determine the conductivities of such solutions by the methods used for metals. Paalzoff showed (*P.* 136, 489) that the method can be applied to other solutions also if we bring the two zinc electrodes into two separate vessels, and establish conduction through a syphon filled with the liquid to be investigated. The process is based on the fact that no polarisation is produced when a current is passed through the surface of contact of different liquids.

But this method is again far surpassed in convenience by one given by F. Kohlrausch (*W.* 11, 653), in which polarisation is made harmless by using alternating currents. Such currents, in which equal quantities of electricity flow alternately in opposite directions, are produced most easily by means of an ordinary induction apparatus. It is true that by such currents the electrodes are also polarised, but the polarisations occur rapidly in opposite directions, so that the polarisation produced by the first current-impact increases the strength of the second current-impact which has the opposite direction, and the polarisation resulting from the latter adds itself on to the third current-impact, and so on. Kohlrausch has shown that by using platinum electrodes of ten sq. cm. surface coated with platinum black, the effect of polarisation may be reduced to less than 0·1 p.c. of the resistance. Kohlrausch uses for his method Wheatstone's bridge in Kirchhoff's arrangement. For details reference is made to Kohlrausch's memoir.[1]

The definition of specific conductivity as given above, and as employed in physics, is not of practical use in considering electrical conductivity from the point of view of the chemist. Since, according to the law of Faraday, the ions alone conduct, and since each ion carries the same quantity of electricity, it is evident that the conductivities of different solutions must be referred to the same number of ions in order to obtain comparable numbers. That we may form a conception of *equivalent conductivity* following from this, let us imagine two electrodes of indefinite extension placed at a distance of 1 cm. apart, and let there be brought between them so much of a solution as contains the equivalent weight in grams of the dissolved electrolyte; the conductivity of such a system is the *equivalent conductivity* of the electrolyte. In order to find the relation between the specific and the equivalent conductivity, we bear in mind that the length of the solution of the electrolyte is 106 times less than 106 cm., which was the length of the conductor assumed in the definition of specific conductivity. When the solution is normal—*i.e.* contains one g. equivalent per litre—the cross-section is 1,000 sq. cm.; when the same weight is dissolved in v litres it is 1,000v sq. cm.; this is 100,000v times greater than the cross-section for the specific conductivity, which is ·01 sq. cm. Hence from the specific conductivity l we obtain the equivalent conductivity λ by the equation $\lambda = 1{\cdot}06 \times 10^7 lv$. It should be remembered that the specific conductivity of an electrolyte is not usually referred to ohms, but to the unit of Siemens, formerly commonly employed, which is equal to the resistance of a column of mercury 100 cm. in length; hence instead of 106 we must put only 100, and the equivalent conductivity becomes $\lambda = 10^7 lv$.

In addition to the equivalent conductivity we can calculate the *molecular conductivity*, which is as many times greater than the equivalent conductivity as the molecular weight contains the equivalent weight. So the molecular conductivity of sulphuric acid is twice as great as the equivalent conductivity, that of aluminium chloride three times as great.

For the general facts which have been established regarding equivalent conductivities we are specially indebted to Kohlrausch, and to several investigators who succeeded him. The most simple relations are exhibited by dilute solutions in which v is greater than 1 lit., and these will be considered first.

1. The equivalent conductivities of normal salts are of the same order of magnitude, but are not the same (Kohlrausch).

2. The conductivities of all salts increase slowly with increase of dilution, and generally reach a maximum value, which is not surpassed after dilutions of 20,000 to 50,000 litres per gram-equivalent (Kohlrausch).

3. The increase of conductivity is least for salts which consist of two monovalent ions; it is about twice as great for salts which contain one divalent and one monovalent ion; and about four times as great for salts whose ions are both divalent (Ostwald).

4. The equivalent conductivities of equally concentrated solutions of the most different salts can be represented as the sum of two constants, one of which is determined solely by the positive ion, the other solely by the negative ion (Kohlrausch). This law agrees the better with experience the more dilute the solutions are.

In order to give an illustration of these laws, I append the equivalent conductivities of several normal salts as measured by Kohlrausch. The values are for 18°.

Dilution	KCl	NaCl	LiCl	$\frac{1}{2}BaCl_2$	$\frac{1}{2}K_2SO_4$	$\frac{1}{2}MgSO_4$
1l	91·9	69·5	59·1	65·8	67·2	27·0
10l	104·7	86·5	77·5	86·1	89·7	47·4
100l	114·7	96·2	87·5	100·6	109·8	71·5
1,000l	119·3	100·8	92·1	109·2	120·7	93·5
10,000l	120·9	102·9	94·3	112·6	124·9	103·4
50,000l	121·7	102·8	95·5	114·4	126·6	105·2
100,000l	121·6	102·4	96·5	114·2	127·5	105·6

If we attempt to form a picture of the processes occurring in electrolytic conduction, we must first bear in mind that, according to the statements of Kirchhoff (*P.* 78, 506), free electricity must be present along the surface of each current-path; and the fall of this potential causes the motion of the electricity inside the conductor. Hittorf pointed out that the theories of electrolysis hitherto held could not satisfy this requirement. Assuming the presence of free ions, it is evident at once that the surface charge is formed by these. Owing to the fall of potential which exists, the positive electricity is now driven to the one side, the negative to the other. Both are bound to the ions; which are, therefore, moved in the same way by forces that are of equal magnitudes on both sides.

---

[1] A detailed description of the method for carrying out such measurements is to be found in *Z. P. C.* 2, 561.

The velocities acquired by the ions under the influence of these equal and opposite forces will not generally be the same, since it cannot be assumed that the resistances to motion encountered by the ions in the solution will be the same. But in dilute solutions, anyhow, the nature of the second ion, travelling in the opposite direction, will have no influence on the velocity of any definite ion—such as, for instance, Cl. Hence the conductivities of salts, when referred to equal quantities of ions, can be represented as the sum of the migration-velocities of the positive and negative ions. Calling these migration-velocities u and v, we get

$$\lambda = u + v.$$

But this is exactly the relation discovered by Kohlrausch (p. 191), to whom also the argument just given is due.

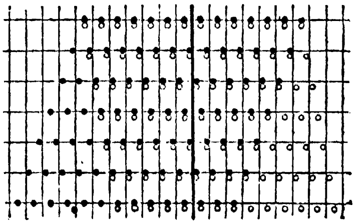
Viewed thus, the phenomena of electrical conductivity are brought into connection with another group of facts, the comprehension of which had presented great difficulties to the older naturalists. These are the phenomena of the '*migration of the ions.*' It has been mentioned that Daniell observed the corresponding manifestations, but they were not explained till Hittorf did so.

From the table already given it follows that the different ions must possess very different migration-velocities. On comparing, for instance, KCl and LiCl, we find differences of 27 to 30 units. Since the chlorine must possess the same velocity in both cases, and hence participate to the same amount in the conductivity, the difference is due solely to the ions K and Li. In the same manner we can convince ourselves that different negative ions migrate with different velocities.

On electrolysing a substance whose ions travel with different velocities, different quantities of the ions will collect at the electrodes, and, in addition to decomposition, the liquid will undergo an unequal change of concentration at the electrodes. In order to get as good a representation as is possible for these relations, let the ions be represented in the figure in the next column by black and white circles. The different horizontal rows represent different phases of the electrolysis, these being such that between them there is a distance equal to the mean distance of the ions. It is assumed that the black ions migrate twice as quickly to the left as the white ones do to the right. At first there are seven ions on each side of the central line. At the end of the process six ions have been liberated at each end, and, in addition, five out of the seven pairs have remained behind at the left side, and two have disappeared; while of the equal quantity at the right side three have remained behind and four have disappeared. Hence the proportion of salt has decreased at the right side twice as much as at the left—that is, *in the same ratio as that in which the two ions migrate.*

Therefore, in order to determine the ratio of the migration-velocities of the two ions of a salt it is only necessary to determine the proportion of undecomposed salt at each electrode before and after electrolysis; the ratio of the decrease of this proportion at each side is equal to the ratio of the migration-velocities, or is the 'migration-measure.'

This representation holds good on the supposition that the ions which separate at the electrodes do not again go into the solution. If, however, we electrolyse a solution of copper sulphate between copper electrodes, the copper, it is true, will leave the solution at the cathode, but the ion SO_4 will not separate out at the anode, but will combine with the copper of the anode to form copper sulphate, which will go into solution. The solution will, therefore, become, not more dilute, but more concentrated. It is, however, easy to take this circumstance into account. It is only necessary to determine the total quantity of electricity passed through the solution (for instance, by means of a silver voltameter); from this we can calculate how much copper has gone into solution, and we need then only deduct this quantity from the total quantity of copper at the anode, as determined by analysis. It is simpler still to weigh the cathode before and after the experiment: the increase of weight is equal to the weight of copper which has dissolved at the anode.



Hittorf examined (*P.* 89 to 106) a great many salts and acids with respect to their 'migration-measures,' and established the fact that the current-strength has no influence on the ratio of the migration-velocities, the temperature has an inappreciably small influence, but the concentration exerts a changeable effect—in some cases it is inappreciably small, while in others it is fairly important.

Hittorf found, for instance, that the concentration of KClAq at the electrodes scarcely changes at all; hence chlorine and potassium must migrate with very nearly equal velocities. If we consider the solution $v = 1{,}000l$ in the table given on p. 191, it follows that of the 119·3 units of conductivity of potassium chloride, 59·65 belong to the chlorine and the same number to the potassium. Knowing these numbers, we can calculate the velocities of migration of all the other ions in the table. NaCl has 100·8; on subtracting from this 59·7 for the chlorine, the velocity of the sodium ion becomes 41·1. Similarly, Li = 32·4, $\frac{1}{2}$Ba = 49·5. As K = 59·7, and as $\frac{1}{2}K_2SO_4 = 120{\cdot}7$, it follows that $\frac{1}{2}SO_4 = 61{\cdot}0$; hence $\frac{1}{2}$Mg = 32·5.

From these numbers we can again calculate the migration-measures, or the changes of concentration at the electrodes, of other salts.

Thus $\frac{u}{v}$ is for NaCl $= \frac{41 \cdot 1}{59 \cdot 7} = 0 \cdot 69$; for LiCl $\frac{32 \cdot 4}{59 \cdot 7} = 0 \cdot 54$; for $BaCl_2$ $\frac{49 \cdot 5}{59 \cdot 7} = 0 \cdot 83$, &c. It is evident that when one migration-measure is known, the migration-measures of all corresponding salts can be calculated from the measured conductivities. And since, on the other hand, the conductivities of salts represent the sums of the velocities of their ions, we can realise the very great simplification which these considerations, due to F. Kohlrausch, have produced in the relations of electrical conductivity which formerly appeared so complicated. If, for instance, we know the conductivities of ten salts with the negative ion A and the positive ions B_1 to B_{10}, and of other ten salts with the ion B_1 and the ions A_1 to A_{10}, and in addition to these the migration-measure of one salt, we can calculate from these 21 measurements the conductivities and the migration-measures of 100 salts – that is, we can deduce 200 data.

An extensive examination of these relations, undertaken by Kohlrausch (*W.* 6, 164), and later by Ostwald (*Z. P. C.* 1, 74), as well as by Loeb and Nernst (*ib.* 2, 948), has proved that they hold good with very sufficient accuracy for very dilute solutions. But deviations from these relations become apparent in concentrated solutions, and these deviations are greater the more concentrated the solutions. And, further, different salts behave differently, inasmuch as salts consisting of two monovalent ions show the smallest deviations, salts with one monovalent and one divalent ion show greater deviations, and salts with two divalent ions show the greatest deviations. Now these are the classes of salts which exhibit differences in the changes of conductivity accompanying dilution (p. 191), and we are, therefore, led to the conclusion that the same cause underlies both phenomena.

The free acids and bases only partially conform to Kohlrausch's law. The following data, taken from Kohlrausch's determinations, exemplify this statement. Temp. = 18° :—

preserving very dilute solutions of alkalis perfectly pure.

From these measurements it follows primarily that hydrogen and hydroxyl possess much greater migration velocities than the other ions – namely, 284 and about 150, respectively. It follows, therefore, that if the law of Kohlrausch were generally valid, the conductivities of all acids would be > 284, and the conductivities of all bases would be > 150. On looking at the numbers in the table, we find that phosphoric acid and acetic acid, as well as ammonia, are at a quite hopeless distance from these values. Sulphuric acid, also, does not obey the law. For $\frac{1}{2}SO_4$ the value 61·0 was found above; on deducting this number from $\frac{1}{2}H_2SO_4 = 331 \cdot 6$, there remains $H = 270 \cdot 6$, and the difference of this value from the one found before, 284, exceeds the limits of experimental error.

On carefully studying the table we now see that the acids and bases which form exceptions to the law exhibit the same peculiarity as the exceptional salts; they change their conductivities very markedly upon dilution. While the substances which follow the law have nearly reached the maximum of the equivalent conductivity at 1000*l*, the numbers show that this is far from being the case in the exceptional substances. We are thus led to inquire as to the cause which brings about the change in conductivity that accompanies dilution.

The arguments used so far have tacitly assumed that all the molecules of the electrolyte participate in the electrical conductivity, and that the electrolyte is therefore completely split into ions. This assumption is evidently arbitrary; and when we remember that aqueous solutions of ammonia and acetic acid exhibit nearly normal lowerings of the freezing-points, and that, therefore, dissociation occurs only to a small extent, if at all, we see that the assumption is completely erroneous in these cases. The former equation $\lambda = u + v$, established without reference to the degree of decomposition, must be changed into $\lambda = x(u + v)$ where x represents the degree of decomposition—*i.e.* the ratio between the molecules decomposed and the total number of molecules orginally present. In doing this we make the most obvious, and probably only possible, assumption, that, *cæteris paribus*, the conductivity is proportional to the number of conducting particles or ions.

Dilution	HCl	HNO_3	$\frac{1}{2}H_2SO_4$	$\frac{1}{3}H_3PO_4$	$CH_3.CO_2H$	KOH	NaOH	NH_4OH
1*l*	278·0	277·0	188·9	29·0	1·2	171·8	149·0	0·84
10*l*	324·4	322·5	208·4	43·0	4·3	198·6	170·0	3·1
100*l*	341·6	339·5	285·5	79·0	13·2	212·4	187·0	9·3
1000*l*	345·6	342·7	331·6	96·8	38·0	214·0	188·0	26·0

Among the substances quoted, HCl, HNO_3, KOH, and NaOH follow the law of Kohlrausch. Thus, if 59·7, which is the migration-velocity of K, is deducted from 118, which represents the conductivity of KNO_3 as determined by Kohlrausch, the difference, 58·3, is the velocity of NO_3. On deducting this number from the conductivity of nitric acid at 1000*l* – that is, from 342·7—it follows that the velocity of hydrogen is 284·4. From HCl = 345·6 it follows that H = 285·9, since Cl = 59·7; these numbers agree to within less than one per cent. In the same way the difference between KOH and NaOH is equal to 26·0, thus approximating to equality with that between KCl and NaCl, which is 19·2. The larger difference proceeds from the difficulty of

We may find a method for determining x in the deviations of electrolytes from the simple laws of solutions with respect to vapour-pressure and freezing-point. We have another and much more accurate method, however, in the determination of the electrical conductivity itself. As was found by Kohlrausch, the equivalent (and also the molecular) conductivity increases with rising dilution, reaching a maximum value in the case of salts within limits which are still practically measurable. We can interpret this behaviour from the standpoint now gained in the sense that the number of molecules split into ions continually increases with increasing dilution, and that the maximum value of conductivity corresponds to a (practically speaking) complete splitting up. Then $x=1$, and the formula $\lambda = x(u+v)$ changes into the former, $\lambda = u+v$. Now, for most salts the maximum value is reached at a dilution of 1000*l*, and the decomposition is nearly complete; it follows from this, that the law of Kohlrausch $\lambda = u+v$ holds good for this maximum dilution. This can be asserted for the strong acids and bases, such as HCl, HNO_3, KOH, and NaOH. On the other hand, as can easily be seen from the course of the numbers, the increase has not nearly reached its limit for acetic acid and ammonia at a dilution $=1000l$; hence the value x is still very far removed from unity, and the law of Kohlrausch cannot hold in its simplest form.

On the assumption that the molecular conductivities of dilute solutions depend only on the number of ions present, the values of x can be easily calculated from a knowledge of the values of the conductivities at different dilutions, as well as of their maximum values; designating the molecular conductivity at the dilution of v litres by μ_v, and the maximum value by μ_∞, then, according to the assumption made, $x = \frac{\mu_v}{\mu_\infty}$.

Whether the above-mentioned assumption is strictly correct cannot be asserted *a priori*. It must be looked upon as probable, since the resistances to motion which the ions experience, and which determine the velocities u and v, depend on the nature of the solvent, which in these cases is water; and considering the small differences which exist between the properties of very dilute solutions and those of water, no appreciable difference in the resistances to motion can be supposed to exist in those differently diluted solutions. But the admissibility of the assumption can also be put to experimental proof in determining x on the one hand by the deviations from the laws of solution, and on the other hand by the equation just given.

If m_0 is the theoretical molecular weight, and m the molecular weight determined from the laws of solution (for instance, from the lowering of the freezing-point), then for electrolytes $m > m_0$; following van't Hoff, we put the ratio of the two $\frac{m_0}{m} = i$. If, on the other hand, x is the number of molecules split up, the total number of molecules being put equal to 1, and if n is the number of ions into which each molecule splits (for KCl $n=2$, for $BaCl_2$ $n=3$, &c.), the number of molecules in the solution will have increased in the ratio $1 : 1-x+nx$, that is, in the ratio $1 : 1+(n-1)x$, and we have, therefore, $i = 1+(n-1)x$.

Arrhenius, to whom we owe this calculation, has shown (*Z. P. C.* 1, 634) that in the greatest number of cases investigated there is an excellent accordance between the values of i as calculated from the electrical conductivities and those deduced from the freezing-points. Individual cases which at first seemed to be exceptions have, on later investigation, also proved to be subject to the law (*Z. P. C.* 2, 491), and the apparent deviations have been shown to be due to incorrect observations. It is only at greater concentrations, where the suppositions made in determining molecular weights from the freezing-points, and those made in determining x from the electric conductivities, become uncertain, and not applicable, that marked deviations are apparent.

In addition to this confirmation of Arrhenius' assumption that in electrolytes a more or less considerable portion of the molecules is split up, a further confirmation has been found by W. Ostwald, which is based on the following considerations (*Z. P. C.* 2, 36, and 270). The spontaneous decomposition which the electrolytic molecules undergo in solutions is of the nature of dissociation; and since, according to van't Hoff, the substances in solution are subject to the gaseous laws, it must be possible to represent the process by the same formulæ as hold for the dissociation of gases. Considering the simplest case, that each molecule splits into two parts, there holds for gases (vol. ii. p. 406) the relation $\frac{p_2^2}{p_1} = \text{constant}$, where p_1 is the partial pressure of the undecomposed portion, and p_2 that of the decomposed portion.

In order to apply this equation to electrolytes, we notice that the pressures are proportional to the numbers of the molecules, and inversely proportional to the volumes occupied by these. If x is the part dissociated, and v the volume, then $p_1 = a\frac{1-x}{v}$ and $p_2 = a\frac{x}{v}$; a represents a factor dependent on the units chosen. Further, according to the former equation, we have $x = \frac{\mu_v}{\mu_\infty}$; introducing these values into the dissociation equation, we get $\frac{1-x}{x^2}v = k$, where k is a constant, and from this $\frac{\mu_v^2}{(\mu_\infty - \mu_v)\mu_\infty} = kv$.

This equation represents a relation between the conductivity and the volume, or the dilution, which must be followed by all binary electrolytes, if the assumptions made are correct.

The equation cannot well be tested in the case of salts, as these very nearly reach complete decomposition; the value $\mu_\infty - \mu_v$ thereby becomes very small, and the experimental errors exert a preponderating influence. Those electrolytes which are only partially dissociated, such as acetic acid &c., lend themselves much better to applying the test. Here also it seems as if a difficulty met us, the quantity μ_∞ not lending itself to direct measurement because, with the very great dilutions necessary, the inevitable impurities of the purest water make accurate measurements impossible. But the law of Kohlrausch provides us with a means for making the measurements. It appears that the *salts* of weak acids are dissociated to just the same extent as those of strong acids; it is possible, therefore, as was shown at pp. 192–3, to calculate the migration-velocity of the negative ion. On adding to this the migration-velocity of hydrogen, which can also be determined (p. 193), the sum represents the conductivity of the completely dissociated acid—that is, μ_∞, the quantity sought (Ostwald, *Z. P. C.* 2, 840).

In this manner, then, we obtain all the data for testing the above equation, and it proves itself to be in direct accordance with the facts. The examination is best carried out by calculating the constant k for a number of values of μ at different dilutions, and seeing whether it really is constant. In the following tables a few examples are given. The numbers hold for 25°, and are molecular conductivities referred to the mercury unit:—

Acetic acid, $\mu_\infty = 364$.

v	μ	$100\frac{\mu}{\mu_\infty}$	k
8	4·34	1·193	0·000180
16	6·10	1·673	179
32	8·65	2·380	182
64	12·09	3·33	179
128	16·99	4·68	179
256	23·82	6·56	180
512	32·20	9·14	180
1024	46·00	12·66	177
			0·000180

The values of k, calculated from eight different measurements, agree within the limits of experimental error.

The osmotic pressure of acetic acid at $v = 8$ corresponds to about three atmospheres, that at $v = 1024$ to about $\frac{1}{45}$ atmosphere, or to 1·7 mm. mercury pressure. The dissociation law has, therefore, proved correct within these wide limits; no examination of the law so far-reaching as this has ever been possible in the case of gases.

Further examples are:—

Cyanacetic acid, $\mu_\infty = 362$.

v	μ	$100\frac{\mu}{\mu_\infty}$	k
16	788·0	21·7	0·00376
32	105·3	29·1	373
64	139·1	38·4	374
128	176·4	48·7	361
256	219·1	60·5	362
512	260·9	72·0	361
1024	297·3	82·1	368
			0·00370

Here also the individual values of the constant vary irregularly about the mean value, so that the discrepancies have to be ascribed to experimental errors.

In the accompanying tables, which have been taken at random from a great number, the dissociation law proves itself everywhere to be accurate. It has, in fact, been verified in every case in the course of an investigation which, for reasons to be discussed later, has been carried out with more than 400 acids, and it can be looked upon as generally valid.

Oxyisobutyric acid, $\mu_\infty = 355$.

v	μ	$100\frac{\mu}{\mu_\infty}$	k
32	20·05	5·65	0·000106
64	28·05	7·91	106
128	38·86	10·95	105
256	53·91	15·20	106
512	73·49	20·70	106
1024	99·52	28·05	106
			0·000106

Oxysalicylic acid, $\mu_\infty = 356$.

v	μ	$100\frac{\mu}{\mu_\infty}$	k
64	84·1	23·6	0·00114
128	112·5	31·6	114
256	147·0	41·3	113
512	187·0	52·6	114
1024	230·0	64·7	116
2048	270·4	76·0	117
			0·00115

Orthochlorobenzoic acid, $\mu_\infty = 356$.

v	μ	$100\frac{\mu}{\mu_\infty}$	k
64	89·2	25·1	0·00131
128	119·4	33·5	131
256	156·1	43·8	133
512	197·0	55·3	133
1024	238·7	67·1	134
			0·00132

We must not omit to remark, however, that, as observed above in the cases of the very strong acids, and the neutral salts, which are very nearly completely dissociated, the calculation of the constants becomes very uncertain, and that greater deviations exist between the observations and the formula than can be ascribed to experimental errors. Which of the assumptions already made will have to be modified in order to explain these small discrepancies cannot as yet be determined; but anyhow the discrepancies are so inconsiderable, and there are so many cases of agreement, that the deviations must be looked upon as of a secondary nature, and undoubtedly they will receive their explanation later on. It is well not to pass over in silence, nor to attempt to hide, such deviations from a law which is otherwise generally valid, since in most cases theoretical progress is connected with the investigation of the causes of deviations from general laws. Examples of this are found in the deviations of gases from the simple laws, and the theory connected with this by van der Waals, and in the deviations of some substances from the law of Avogadro and the elucidation thereof by the theory of dissociation.

Chemical applications.—The laws of electrical conductivity, as developed in the preceding pages, give us the means for solving many chemical problems. This they do, because they ive a deeper insight into the constitution of issolved substances than is afforded by the isual chemical methods. A series of such appliations is already contained in the preceding ages; others are considered in the following aragraphs.

The first of these applications is connected vith the question as to the nature and composiion of the current-conducting particles or ions f salts. The conception of Berzelius that these re the 'anhydrous' acid and base has, in the ight of Faraday's law, been recognised as erroeous. Afterwards, in analogy with the comounds of organic chemistry, the salts were looked ipon as having a unitary composition, and this iew is still generally held. But this conception annot be regarded as quite correct, since it does not take into account the fundamental difference which undoubtedly exists between salt-like compounds and indifferent compounds, a difference which manifests itself chiefly in the capacities for reaction of the two groups. The conception of Berzelius rested on the correct recognition that salts are dual compounds; he had only misconceived their constituents.

The new electro-chemical theory of Arrhenius avoids both errors, and retains what is correct in each conception. The solid salts, and, according to concentration, a greater or smaller portion of the salts dissolved in water, 'salt' being understood to include acids and bases, have, it is true, a unitary composition; but that portion of them which is capable of reacting chemically, and which therefore is of preponderating interest to the chemist, is split binarily.

'Salts,' in the general meaning, are therefore substances which very readily undergo such a binary splitting, and herein lies their binary character, correctly recognised by Berzelius.

It is a most remarkable fact that in the splitting up of 'salts' their constituents appear in oppositely charged electrical conditions. This indicates that probably both phenomena stand in the closest connection. It may be asked whether the salts split up so easily because their parts readily acquire opposite electric charges, or, conversely, whether the parts are easily charged electrically because they are readily separated. Not less remarkable is the fact that whenever a salt molecule is split up an equal quantity of electricity is produced (or separated), independently of the nature of the parts. It is beyond doubt that this fact is of decisive importance for the recognition of the nature of electricity, as well as of that of chemical affinity; when the one is elucidated, the other will be so also. But which of the two will first be thus advanced cannot as yet be foreseen.

A further remarkable fact is, that pure salts at ordinary temperatures do not conduct appreciably; the ordinary solid salts do so as little as pure sulphuric acid, acetic acid, &c. Even the halogen acids HF, HCl, HBr, and HI, when liquefied by pressure or cold, are all non-conductors. According to the dissociation theory of electrolytes this is quite conprehensible; the pure substances do not conduct because they are not dissociated, and they are not dissociated because their molecules have no space wherein to dissociate, or because they do not possess sufficient mobility.

Whether dissociation occurs or not when salts are dissolved depends in a marked way on the nature of the solvent. Hydrochloric acid, which when liquid is not dissociated, dissociates at once when dissolved in water. But on using as solvent benzene, xylene, hexane, or ether, no dissociation ensues; these solutions are non-conductors (Kablukoff, *Z. P. C.* 4, 430). On using alcohols as solvent, methyl alcohol is found to behave almost like water; the solutions of hydrochloric acid in it have a molecular conductivity about three times smaller than aqueous solutions. The conductivities of the solutions become less and less as we use ethyl alcohol, isobutyl alcohol, and isoamyl alcohol.

It is still quite unknown what the condition is which determines the property of different solvents to cause dissociation to a different degree, and it is not known whether, as is somewhat probable, these effects remain proportional in the cases of all salts. Here it seems, however, as if the capability of the solvent itself to separate into ions, even if to a small degree only, determined its power to cause the dissociation of substances dissolved in it.

Although the questions just mentioned still await solution, partly for lack of experimental researches in this domain, yet the new conception of the binary character of salts allows us to distinguish more sharply between the different classes of these compounds than was possible before. This is especially so in the case of the so-called *double salts*. This name is at present somewhat uncertain in its application. Potassium copper sulphate $K_2SO_4.CuSO_4$ is called a double salt, but sodium platinichloride is also formulated as such, $2NaCl.PtCl_4$; the first formula is correct, but the latter is wrong. This is so because potassium copper sulphate gives all the reactions of potassium sulphate as well as those of copper sulphate, but from sodium platinichloride silver solutions do not precipitate silver chloride as from sodium chloride, but silver platinichloride Ag_2PtCl_6 (Jörgenson, *J. pr.* [2] 16, 345). It is probable, therefore, that sodium platinichloride is a salt of chloroplatinic acid H_2PtCl_6. If this is correct, the ions of the sodium salt are 2Na and $PtCl_6$, and in electrolysis the platinum must not, like the other metals, go to the cathode, but as a constituent of the acid radicle to the anode. And, in fact, Hittorf has proved (*P.* 106, 520) that this is the case.

Similarly with other salts; for instance, that which is obtained from chromium oxide and potassium binoxalate, and which has the empirical formula $3K_2C_2O_4.Cr_2(C_2O_4)_3$. Since this salt gives no pp. with calcium salts it cannot be regarded as an oxalate. In fact, in electrolysis the chromium goes to the anode; the chromium is, therefore, a constituent of the acid radicle, and the salt must be looked upon as the potassium compound of a tribasic chromoxalic acid $(HC_2O_4)_3Cr$—that is, as $K_3C_6O_{12}Cr$ (Kistiakowsky, *Z. P. C.* 6, 107).

Such salts, therefore, are not double salts, but are salts of complex acids; it is possible to test, in the way already indicated, in every case whether a definite salt is a true double salt or the salt of a complex acid. On examination we find that, not a double salt, but a salt of a complex acid is present whenever the reactions of the salt in question are not those of its constituents. This decision is specially convenient when the solution of the salt is coloured. Because, since the properties of the positive ions, and therefore their colour also, are independent of the negative ions, it will always be possible to conclude that the positive ions are no longer present when their colouration disappears. In the easily decomposable salt $2KCN.Ni(CN)_2$ we must not see a double salt, but the potassium salt of cyano-nickelic acid $H_2Ni(CN)_4$, because its solution is yellow, and not green as solutions of the nickel salts are which contain nickel as an ion.

The line of demarcation between the two groups of salts, however, is not absolute, as many salts exist which in aqueous solutions are both double salts and also complex ones. This is the case with potassium ferri-oxalate, for instance. Since this salt is green, while all true ferric salts are yellow or brown, it may be concluded that it is a complex salt, the compound of a ferri-oxalic acid $H_3C_6O_{12}Fe$ analogous to the above-mentioned chromo-oxalic acid. The solution of this salt gives, however, a precipitate with calcium solutions, which proves it to be an ordinary oxalate, but on the other hand the iron goes to the anode. From this it is seen that the aqueous solution contains chiefly the ions $3K + C_6O_{12}Fe$, but that a portion of the salt has split in the manner of a double salt into potassium oxalate and ferric oxalate, which on their part form the corresponding ions.

The study of such cases has as yet scarcely been begun, because until now we possessed neither theoretical nor experimental means for answering the questions which arise. The electrical methods, in conjunction with the methods for the determination of molecular weights arising out of the theory of solutions, now afford easy access to these hitherto closed and uncultivated domains.

The dissociation-constants of organic acids. The only province of chemistry which has been studied somewhat thoroughly in the light of the new electro-chemical theory is that of the organic acids. We have seen above that the molecular conductivity of these can be represented by the formula $\frac{\mu^2_v}{(\mu_\infty - \mu_v)\mu_\infty} = kv$. This formula contains only the single constant k, which constant depends on the nature of the acid, the temperature, and the solvent, but is independent of the dilution. At a given temperature, and in the same solvent, the quantity k is therefore a measure of the electrical conductivity, and hence it is the capacity for reaction of the acid; for the substance considered, k therefore represents the long sought for *numerical value of the chemical affinity.*

It is remarkable that the two conflicting views concerning the nature of chemical affinity, as represented by Bergmann and Berthollet (*cf.* vol. i. 68) here coincide. Berthollet, who represented the affinity as dependent on the mass, was right, and so was Bergmann, who desired to represent it by a constant. By accurately formulating the idea of the influence of mass as given by Berthollet, we obtain in the equation for the chemical effects a co-efficient independent of the quantity—that is, one referred to the chemical unit of quantity, which is Bergmann's measure of chemical affinity.

It has already been shown (vol. i. 81) that the electrical conductivities bear a definite relation to the composition and constitution of the acids. But the law of dissociation of electrolytes had not been discovered at the time when the article referred to was written, and the observed relations could not be represented numerically. This has now become possible, by means of the values of the constant k, which have been measured for about 400 acids (Ostwald, *Z. P. C.* 3, 170; Bethmann, *ib.* 5, 385; Bader, *ib.* 6, 289).

Before expounding these relations, it will first be shown how the laws which have been found empirically for the electrical conductivities follow directly from the above dissociation-formula. In order to make the consideration easier, the formula will first be somewhat simplified by substituting for the molecular conductivity μ_v its value referred to the maximum $\frac{\mu_v}{\mu_\infty} = m$. The equation then assumes the simple form $\frac{m^2}{1-m} = kv$.

In the first place, we see that as the dilution v increases infinitely, the quantity $1-m$ must approach zero. Hence m must approach unity; hence the electrical conductivity increases with dilution up to a maximum, as has been shown by experience.

Further, it was found that when at any dilutions, v_1 and v_2, two different acids have the same (relative) conductivity, they also have the same at other dilutions v_1' and v_2', as long as the new dilutions are in the same ratio as the old ones—that is, when $v_1 : v_2 = v_1' : v_2'$. This follows from the formula in this way: on the supposition that the relative conductivities are the same, we have first of all $\frac{m^2}{1-m} = k_1v_1$; $\frac{m^2}{1-m} = k_2v_2$; therefore $k_1v_1 = k_2v_2$. And in the same way for the other dilutions, $k_1'v_1' = k_2'v_2'$, from which it follows directly that $v_1 : v_2 = v_1' : v_2'$.

In addition, F. Kohlrausch had already pointed out that in the cases of acids which conduct badly (which, therefore, are but little dissociated), the molecular conductivity increases nearly as the square root of the dilution. If in the equation $\frac{m^2}{1-m} = kv$, m is very small, $1-m$ differs little from unity, and can be looked upon as constant; then approximately, $m^2 = kv$, or $m = \sqrt{kv}$.

Finally, on taking the logarithms of the dilutions as abscissæ and the values of m as ordinates, we also get from the formula a curve resembling a tangent-function (vol. i. page 82); the interpolation-formula given in vol. i. must be replaced by the present rational formula.

As regards the meaning of the constant k, we recognise what this is on putting $m = 0{\cdot}5$, when we get $2k = \frac{1}{v}$. $2k$ is therefore the reciprocal value of the volume, or the concentration at which the electrolyte is just half dissociated. This number is extremely characteristic for different acids, since its value may vary according to the nature of the substance between the limits 1 and 1,000,000.

The measurement of the quantity *k* for different acids has led to the following general law:—*The constant* k *is approximately the product of a number of factors, each of which depends on the nature of the constituents of the acid and on their position relatively to the carboxyl group.*

In order to realise what this law implies, and in what manner it is applied, we will proceed to discuss in the following pages the most important groups of the organic acids. The relations, the main features only of which could formerly (vol. i. page 82) be investigated, can now be represented numerically with perfect exactitude. The numerical values for *k* have been multiplied by 100 in order to get rid of ciphers; they all hold for aqueous solutions at 25°.

The fatty acids. The following constants were measured:—

Formic acid $H.CO_2H$	0·00214
Acetic acid $CH_3.CO_2H$	0·00180
Propionic acid $C_2H_5.CO_2H$	0·00134
Butyric acid $C_3H_7.CO_2H$	0·00149
Isobutyric acid $(CH_3)_2CH.CO_2H$	0·00144
Isovaleric acid $(CH_3)_2C_2H_3.CO_2H$	0·00161
Caproic acid $C_5H_{11}.CO_2H$	0·00145

Formic acid has the highest constant; the replacement of its hydrogen by methyl reduces the constant to half its value. But on again replacing one hydrogen atom in acetic acid by methyl the constant only decreases to $\frac{1}{1\cdot4}$ of its value, and further similar substitutions no longer produce a weakening of the acid, but some of them even bring about a slight strengthening. These changes are, however, but small, so that the constants of acids of this series having more than three carbon atoms vary irregularly about the mean value 0·0014.

It is evident, then, that the substitution of hydrogen by methyl acts quite differently, according as it occurs next to the carboxyl or at a greater distance from it. This is a result which will afterwards be shown to hold good in all cases; on the whole, the effect of each substituent is the smaller the more distant it is from the carboxyl. The inference that the interposition of even two carbon atoms nearly counteracts the effect is correct for methyl, for which it is relatively small. Other constituents of greater energy extend their action further, but yet not over more than three or four atoms of the 'open chains'; in the case of 'closed chains' other relations hold good.

Halogen derivatives of the fatty acids. The entrance of chlorine in the place of hydrogen in the fatty acids exerts very considerable influence. The constants are—

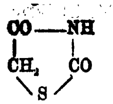
Acetic acid $CH_3.CO_2H$	0·0018
Monochloracetic acid $CH_2Cl.CO_2H$	0·155
Dichloracetic acid $CHCl_2.CO_2H$	5·1
Trichloracetic acid $CCl_3.CO_2H$	121

The constants are in the ratio of

1 : 86 : 2840 : 67200. The ratio of the values of the constants for the different acids, referred to the entrance of each separate chlorine atom, is 84, 33, and 24. It is only the ratios of the constants, and not their differences, which are important; the ratios, though not equal, are yet of the same order of magnitude, while the differences between 0·155, 5, and 121 are quite incomparable. Further, it follows that the relative change of the constants for the entrance of each chlorine atom is not of the same value; the first chlorine atom acts more intensely than the second, and the second more intensely than the third. We shall again meet with a similar relation when dealing with substitution in connection with the same carbon atom. From this it may be concluded that the first chlorine atom which enters into acetic acid exerts its influence under more favourable conditions, therefore probably from a less distance, than the second and third, and it becomes evident how well such measurements lend themselves to investigations and examinations of the relations in space of the atoms within the molecules. The action of other elements and radicles is very similar to that of chlorine.

Monobromacetic acid $CH_2Br.CO_2H$	0·138
Cyanacetic acid $CH_2.CN.CO_2H$	0·370
Thiocyanacetic acid $CH_2.SCN.CO_2H$	0·265
So-called 'carbamine thioglycollic acid' $CH_2(SCONH_2)CO_2H$	0·0246
Isothiocyanacetic acid $C_3H_3O_2S.N$	0·0000246
Thiacetic acid $CH_3.COSH$	0·0469

The constant of monobromacetic acid does not differ much from 0·155, that of monochloracetic acid, hence both halogens exert about the same influence. Cyanogen acts much more intensely. The ratio of cyanacetic acid to acetic acid has risen to 205 (from 86). Thiocyanacetic acid also is stronger than monochloracetic acid, but not so strong as cyanacetic acid, though sulphur is generally a negative substituent—that is, one which augments the acid properties. The idea of relations in space at once suggests itself; by the introduction of sulphur there has, in fact, taken place, on the one hand, an increase in the acid properties, but on the other hand, since the cyanogen is removed to a greater distance from the carboxyl, there has been a weakening, and the latter effect preponderates over the former. By taking up water, thiocyanacetic acid easily passes into the acid $CH_2.SCONH_2.CO_2H$, the group CN changing into $CO.NH_2$. This transformation is accompanied by a marked decrease in the conductivity, the constant falling to less than a tenth of its former value. The change can be conveniently studied in an aqueous solution of thiocyanacetic acid, by determining its electrical conductivity; the conductivity decreases continuously, and after even a few days the greater part of the thiocyanacetic acid is found to be changed. Finally, there is a compound isomeric with thiocyanacetic acid, which Volhard (*J. pr.* [2] 9, 6) obtained by the action of hydrochloric acid on sulphohydantoïn, and which is isothiocyanacetic acid. The constant for this compound is 10,000 times smaller than that for thiocyanacetic acid; it is also smaller than that of any other carbon acid, so that the inference must be drawn that the substance is not a carbon acid at all. This confirms the view expressed by Liebermann, and the reasons for which were given by Hantzsch (*B.* 20, 3129), that the compound is a dioxythiazole—



The feebly acid properties are ascribed to the hydrogen of the imide group. The thiacetic acid mentioned at the end of the last table contains sulphur in the place of oxygen in the hydroxyl of the carboxyl. In accordance with the negative nature of sulphur, this acid proves to be twenty-six times stronger than acetic acid, and this factor may be looked upon as the greatest to which sulphur can give rise when replacing oxygen, because in this case the sulphur atom acts from the most favourable position which is ever possible.

Oxyacetic acid and its derivatives.

Glycollic acid $CH_2.OH.CO_2H$ . . .	0·0152
Methoxy-acetic acid $CH_2.(OCH_3)CO_2H$.	0·0335
Ethoxy-acetic acid $CH_2(OC_2H_5)CO_2H$.	0·0234
Phenoxy-acetic acid $CH_2(OC_6H_5)CO_2H$.	0·0756
Glyoxylic acid $CH(OH)_2CO_2H$ . .	0·0474

The replacement of hydrogen by hydroxyl in acetic acid produces a rise in the constant of 9 times its former value; hydroxyl, therefore, acts much less intensely than the halogens. By introducing a second hydroxyl the constant again becomes greater, but only 3·1 times greater. Here we find quite the same effects as in the cases of mono- and di-chloracetic acid, the second substitution of the same substance acting less strongly than the first. In the numerical values, even, we cannot overlook a certain correspondence; in the case of chlorine the ratios are 1:86 and 1:33; in the case of hydroxyl they are 1:9, and 1:3·1. It may therefore be said that, using round numbers, in the derivatives of acetic acid chlorine acts ten times as intensely as hydroxyl. When the hydroxylic hydrogen of glycollic acid is replaced by radicles, the constant changes, and, strange to say, methyl acts in this case in a strengthening manner, the constant rising to a little more than twice its former value. The substitution of hydrogen in this methyl by methyl again has a weakening effect, as is the case with the fatty acids; ethoxy-acetic acid is 1·4 times weaker than methoxy-acetic acid. Finally, by the introduction of phenyl, the constant becomes appreciably greater; it is about five times as great as that of glycollic acid, and is 2·3 times greater than that of methoxy-acetic acid. The ratio is smaller than that between acetic acid and benzoic acid, which is 1:3·3, an indication that the exchange of methyl for phenyl has in the latter case taken place in greater proximity to the COOH group, a conclusion which follows also directly from the formulæ.

A number of other substances related to glycollic acid have given the following numerical values:—

Thioglycollic acid $CH_2(SH)CO_2H$ . .	0·0225
Thiodiglycollic acid $S(CH_2CO_2H)_2$.	0·048
Dithiodiglycollic acid $S_2(CH_2CO_2H)_2$.	0·065
Diglycollic acid $O(CH_2CO_2H)_2$ . .	0·11

As the constant of glycollic acid is ·0152, we see that the substitution of S for O in hydroxyl has caused the constant to increase 1·5 times; now, as substitution of S for O in COOH of acetic acid increased *k* from 1 to 26, we see here also the great influence of the position occupied by the replacing atom.

The three other acids quoted in the last table are dibasic, and the question at once arises how their constants must be calculated, since the dissociation-formula has been developed for binary electrolytes—that is, for monobasic acids only, and not for ternary ones, to which class the dibasic acids belong. It can, however, easily be shown that, as long as the dissociation is not great, the weaker dibasic acids are not electrolysed according to the formula $2H + R''$, but according to the formula $H + HR$. In other words, at first one hydrogen atom only is split off, and the dissociation takes place according to the binary scheme of the monobasic acids. This follows from the fact that the change in the molecular conductivity of such acids can be represented by the same formula $\frac{m^2}{1-m} = vk$, so that *k* remains constant. But the formula calculated on the assumption of a dissociation according to the scheme $H_2R'' = 2H + R$ does not represent the change in the conductivity of these acids as determined by experiment.

Malonic acid $CH_2(COOH)_2$ may serve as an example of dibasic acids. It gives:—

v	μ	m	$100k$
16	53·1	0·149	0·159
32	72·3	0·202	0·159
64	97·1	0·272	0·158
128	128·5	0·359	0·157
256	165·9	0·464	0·157
512	208·8	0·586	0·162
1024	253·2	0·708	0·168
2048	294·2	0·823	0·187

The constant does not change till the value $m = 0·586$ is reached—that is, till about half the acid has been dissociated according to the binary scheme; then it becomes greater—a sign that henceforward the formula loses its validity, and that the decomposition according to the ternary scheme $2H + R''$ begins to assume an appreciable value.

If, on the other hand, we attempt to calculate the conductivity according to the formula corresponding to ternary dissociation $\frac{m_2}{(1-m)v^2} = k$, the values of *k* decrease very rapidly and are far from being constant.

The values for the constants of dibasic acids given in the table preceding the last one have been calculated on this principle, and refer, therefore, to the first stage of binary dissociation $H_2R = HR + H$.

Comparing thioglycollic acid with thiodiglycollic acid and dithiodiglycollic acid, we find that the constants do increase distinctly, though only slightly; they are 0·0255, 0·048, and 0·065, and are in the ratio of 1:2·1:2·9. When, therefore, the residue of acetic acid, CH_2CO_2H, enters thioglycollic acid, this process has no appreciable influence on the constant. On the other hand, the constant of diglycollic acid is 7·2 times greater than that of glycollic acid. From the fact that the same substituent produces such different effects in glycollic acid and in thioglycollic acid, it may be presumed that in the first case the oxygen brings the negative substituent nearer to the carboxyl than the sulphur does in the second case, and this presumption may be further utilised for hypotheses concerning the configuration of the sulphur atom, and the arrangement of the affinity points on it. It has, however, not yet been established with certainty that the greater or less distance of the groups is the *only* cause of their different actions, and there are some circumstances which allow us to conclude that other conditions are effective also; therefore, until these have been cleared up, conclusions such as the above hold only hypothetically.

Derivatives of amido-acetic acid.

Phenylamido-acetic acid $CH_2(NHC_6H_5)CO_2H$	0·0039
Hippuric acid $CH_2(NH.CO.C_6H_5)CO_2H$	0·0222
Aceturic acid $CH_2(NH.CO.CH_3)CO_2H$	0·0230
Phthalylamido-acetic acid $CH_2(NC_2O_2C_6H_4)CO_2H$	0·100

Amido-acetic acid has not the character of an acid; the basic NH_2 group completely removes the acid properties of acetic acid. But if negative radicles are introduced into NH_2, well defined acids are again obtained. Phenyl has this effect; the constant of phenylglycocoll is 2·2 times as great as that of acetic acid. The constants of the acids obtained by introducing $CO.C_6H_5$ and $CO.CH_3$ for H in NH_2 are 12 to 13 times greater than that of acetic acid. The substitution of the divalent residue of phthalic acid for the two hydrogen atoms in the NH_2 group raises the constant of acetic acid 55 times.

Derivatives of propionic acid.

Propionic acid $CH_3.CH_2.CO_2H$	0·00134
Lactic acid $CH_3.CH(OH)CO_2H$	0·0138
β-Oxypropionic acid $CH_2(OH).CH_2.CO_2H$	0·00311
Glyceric acid $CH_2.OH.CH.OH.CO_2H$	0·0228
β-Iodopropionic acid $CH_2I.CH_2.CO_2H$	0·0090
Trichlorlactic acid $CCl_3.CH.OH.CO_2H$	0·465

The constant of α-oxypropionic or lactic acid is 10 times greater than that of propionic acid, but the constant of β-oxypropionic acid is only 2·3 times greater than that of propionic acid. The difference in the action of the same substituent, according to its nearer or more distant position relatively to COOH, asserts itself most clearly. The ratio between propionic acid and lactic acid is slightly greater than that between the analogous substances acetic acid and glycollic acid (1 : 9); it is, therefore, not quite immaterial whether the substitution does or does not take place in the group CH_3. The influence of the more distant position of the substituent can be recognised in β-iodopropionic acid and trichlorolactic acid. The first is only 6·5 times stronger than the parent substance. No measurement of α-iodopropionic acid has yet been made, but there is little doubt that iodine in the α- position must act very similarly to chlorine or bromine, and must, therefore, increase the constant by 70 or 80 times. The effect in the β- position is 10 to 12 times less than this. In the same way the substitution of 3Cl for 3H in $CH_3.COOH$ increases *k* about 67,000 times; but the introduction of 3Cl into $CH_3.CHOH.COOH$ in the β- position increases *k* only about 33·7 times. The ratio of these effects is about 1:2000; calculated for each Cl atom the ratio is $\sqrt[3]{2000} = 12{\cdot}6$; this ratio comes very near that estimated for α- and β-iodopropionic acids.

Derivatives of higher fatty acids.

Oxyisobutyric acid $(CH_3)_2CH.OH.CO_2H$	0·0106
Mononitrocaproic acid $C_5H_{10}(NO_2).CO_2H$	0·0123
Dinitrocaproic acid $C_5H_9(NO_2)_2CO_2H$	0·069
Lævulinic acid $CH_3.CO.CH_2.CH_2.CO_2H$	0·00255

Since the constant of isobutyric acid is 0·00144, the hydroxyl in the α- position here causes the factor 7·4, which is somewhat smaller than 9, the corresponding ratio between acetic acid and glycollic acid.

The ratio between caproic acid and its mononitro- derivative is 1 : 8·5. Since, as will soon be shown, the nitro- group has a more strongly negative action than chlorine, NO_2 must, in the present case, be in the β- position. The same holds for the dinitro- compound; it is 5·6 times stronger than the mononitro- compound; it is again evident that the second negative group has less effect than the first.

Lævulinic acid, or β-acetyl-propionic acid, allows us to recognise the smaller influence to be expected of the acetyl in the β- position; the constant is only 1·9 times larger than that of propionic acid.

Benzoic acid and its derivatives. The largest and most varied group of allied substances that has been investigated so far, is that of benzoic acid and its derivatives, and consequently it has been possible to trace here many and striking regularities.

Benzoic acid $C_6H_5CO_2H$	0·0060
Salicylic acid $C_6H_4(OH)CO_2H$	0·102
m-Oxybenzoic acid $C_6H_4(OH)CO_2H$	0·0087
p-Oxybenzoic acid $C_6H_4(OH)CO_2H$	0·00286
Oxysalicylic acid [1:2:3] $C_6H_3(OH)_2CO_2H$	0·114
Oxysalicylic acid [1:2:5] $C_6H_3(OH_2)_2CO_2H$	0·108
β-Resorcylic acid [1:2:4] $C_6H_3(OH)_2CO_2H$	0·052
α-Resorcylic acid [1:2:6] $C_6H_3(OH)_2CO_2H$	5·0
Protocatechuic acid [1:3:4] $C_6H_3(OH)_2CO_2H$	0·0033
m-Dioxybenzoic acid $C_6H_3(OH)_2CO_2H$	0·0091
Gallic acid [1:3:4:5] $C_6H_2(OH)_3CO_2H$	0·0040
Pyrogallic acid [1:2:3:4] $C_6H_2(OH)_3CO_2H$	0·055
Phloroglucin carboxylic acid [1:2:4:6] $C_6H_2(OH)_3CO_2H$	2·1

The numbers indicate the positions of the OH groups relatively to COOH supposed to be in position 1.

This table contains the constants of all hydroxyl-benzoic acids known up to the present time. These show such close connections with each other that, knowing the constants of benzoic acid and of the three monoxybenzoic acids, those of all the others can be calculated approximately. It is true the calculation is not quite exact, but it is sufficiently so to enable us to deduce the constitutions of the corresponding substances directly from a knowledge of the constants.

Between the constants of benzoic acid and its ortho-oxy- derivative the ratio is 1:17. This value is larger than the ratio when OH is introduced in the α- position into a fatty acid, in which cases the ratio did not exceed 10; in the β- position, which corresponds to the constitution of salicylic acid, the ratio was not larger than 2·3. From this it appears that the ortho- position involves a much closer relation in the benzene nucleus than even the α- position in the open chain, a fact which later on will be confirmed in many ways, and which seems to be of great importance in dealing with the question concerning the constitution of benzene.

The constant is increased but slightly by OH in the meta- position. But in the para- position the hydroxyl even produces a diminution of the constant to rather less than half the value. We deal in this case, therefore, not only as usual with a greater or smaller value of the influence exerted by a substituent according to its position, but with a reversal of the *direction* in which the influence is exerted. This fact, which has already become evident in the case of methyl, recurs with other feebly negative substituents in the para- position of the benzene nucleus. This promises to become very important in the construction of a theory to explain these phenomena.

We have then the following factors for the influence of the hydroxyl:—

Ortho- 1:2 or 1:6 = 17
Meta- 1:3 „ 1:5 = 1·4
Para- 1:4 = 0·5

By their help we are able to calculate the constants of the di- and tri-oxybenzoic acids by multiplying the constant of benzoic acid by the corresponding factor for every hydroxyl introduced. It must be remembered that such a calculation can only give approximate results; for we have seen that substituents already present somewhat influence the magnitude of the factor of a newly entering substituent, and that, generally, by decreasing it. It is, therefore, only the order of magnitude of the constants, and not their exact value, that we shall be able to find in the manner indicated.

Four dioxybenzoic acids can be derived from salicylic acid; the constants of these four acids are calculated thus:—

1:2:3 gives $\cdot 0060 \times 17 \times 1\cdot 4 = 0\cdot 143$
1:2:4 „ $\cdot 0060 \times 17 \times 0\cdot 5 = 0\cdot 051$
1:2:5 „ $\cdot 0060 \times 17 \times 1\cdot 4 = 0\cdot 143$
1:2:6 „ $\cdot 0060 \times 17 \times 17 = 1\cdot 73$

The numbers observed are 0·114, 0·052, 0·108, and 5·0. In the case of the first and the third acid which both contain a hydroxyl in the *m*- position, a diminution of the combined effect therefore makes itself felt as usual. In the second acid 1:2:4, calculation and experiment completely agree; while the fourth acid 1:2:6, which contains two ortho- hydroxyls, shows a value about three times greater than is furnished by the estimation. We shall see later that this behaviour is common; two substituents in the ortho- position do not, as is otherwise usual, weaken one another, but reinforce each other's effect.

For the two dioxybenzoic acids still remaining we must expect the following constants:

1:3:4 gives $\cdot 006 \times 1\cdot 4 \times 0\cdot 5 = 0\cdot 0042$
1:3:5 „ $\cdot 006 \times 1\cdot 4 \times 1\cdot 4 = 0\cdot 012$

Measurement gives ·0033 and ·009, both constants being therefore as usual somewhat smaller, a consequence of the combined effect, yet being quite of the expected order of magnitude.

The six possible trioxybenzoic acids allow us to estimate the following constants:

1:2:3:4 gives $\cdot 0060 \times 17 \times 1\cdot 4 \times 0\cdot 5 = 0\cdot 07$
1:2:4:6 „ $\cdot 0060 \times 17 \times 0\cdot 5 \times 17 = 0\cdot 9$
1:3:4:5 „ $\cdot 0060 \times 1\cdot 4 \times 0\cdot 5 \times 1\cdot 4 = 0\cdot 006$
1:2:3:5 „ $\cdot 0060 \times 17 \times 1\cdot 4 \times 1\cdot 4 = 0\cdot 2$
1:2:4:5 „ $\cdot 0060 \times 17 \times 0\cdot 5 \times 1\cdot 4 = 0\cdot 07$
1:2:3:6 „ $\cdot 0060 \times 17 \times 1\cdot 4 \times 17 = 2\cdot 4$

Of the six possible trioxybenzoic acids three are known and measured. The comparison between the observed and estimated constants gives 0·055 instead of 0·07; 0·004 instead of 0·006, where as usual the observed value is smaller than the estimated value; and in the case of the acid with two hydroxyls in the ortho- position we have 2·1 observed instead of 0·9 estimated, which therefore, as before, is about twice as great. In the same way we may expect in the cases of the three trioxybenzoic acids still unknown, that the real constants of the acids 1:2:3:5 and 1:2:4:5 will be somewhat smaller than the estimated values, and therefore about 0·15 and 0·05, while the third acid 1:2:3:6 with two ortho- hydroxyls will probably have a constant from 5 to 5·5. In spite of the uncertainty of the estimation, the differences are so considerable that when in future one of these acids is prepared the determination of the conductivity of an aqueous solution will suffice to decide its constitution.

The constitutional relations of the oxybenzoic acids, as indicated by the dissociation-constants, are therefore in complete agreement with those deduced from chemical relations.

The methods just expounded may be directly utilised for elucidating constitutional relations. On heating orcin $C_6H_3(OH)_2CH_3$ with $KHCO_3$ there is formed 'paraorsellic acid,' whose constitution must correspond either to that of α- or β-resorcylic acid. On measurement, the constant appeared to be 4·1; the acid has, therefore, a constitution analogous to that of α-resorcylic acid, corresponding to the arrangement $CO_2H:OH:OH:CH_3 = 1:2:6:4$.

Further substitution products of benzoic acid gave the following numbers:—

o-Chlorobenzoic acid $C_6H_4Cl.CO_2H$	0·132
m-Chlorobenzoic acid $C_6H_4Cl.CO_2H$	0·0155
p-Chlorobenzoic acid $C_6H_4Cl.CO_2H$	0·0093
o-Bromobenzoic acid $C_6H_4Br.CO_2H$	0·145
m-Bromobenzoic acid $C_6H_4Br.CO_2H$	0·0137
Monobromgallic acid $C_6HBr(OH)_3CO_2H$	0·059
Dibromgallic acid $C_6Br_2(OH)_3CO_2H$	1·21
m-Fluobenzoic acid $C_6H_4F.CO_2H$	0·0136
m-Cyanobenzoic acid $C_6H_4CN.CO_2H$	0·020
o-Nitrobenzoic acid $C_6H_4NO_2.CO_2H$	0·616
m-Nitrobenzoic acid $C_6H_4NO_2CO_2H$	0·0345
p-Nitrobenzoic acid $C_6H_4NO_2CO_2H$	0·040
Bromonitrobenzoic acid [1:2:5] $C_6H_3BrNO_2CO_2H$	1·4
o-Amidobenzoic acid $C_6H_4NH_2CO_2H$	0·0010
p-Amidobenzoic acid $C_6H_4NH_2CO_2H$	0·0012
o-Acetamidobenzoic acid $C_6H_4(NHCOCH_3)CO_2H$	0·024
m-Acetamidobenzoic acid $C_6H_4(NHCOCH_3)CO_2H$	0·0085
p-Acetamidobenzoic acid $C_6H_4(NHCOCH_3)CO_2H$	0·0052
o-Acetoxybenzoic acid $C_6H_4(OCOCH_3)CO_2H$	0·033
p-Acetoxybenzoic acid $C_6H_4(OCOCH_3)CO_2H$	0·0042

m-Acetoxybenzoic acid $C_6H_4(OCOCH_3)CO_2H$ . .	0·0099
o-Methoxy-benzoic acid $C_6H_4(OCH_3)CO_2H$ . . .	0·0082
p-Methoxy-benzoic acid $C_6H_4(OCH_3)CO_2H$ . . .	0·0032

The same conclusion may be drawn from these numbers as to the influence of the halogens as had been deduced for hydroxyl—namely, that the ortho- position is that of greatest influence. The constant of benzoic acid rises to 22 times its value on the introduction of chlorine in the ortho- position, to 2·6 times its value when Cl is put in the meta- position, and to 1·5 times its value when Cl is put in the para- position. But along with this there is a remarkable difference between the behaviour of OH and that of Cl; hydroxyl acts much more strongly in the ortho-position of the benzene nucleus than in the α- position of the open chain, while chlorine, which in the α- position of the open chain increases the constant to more than 80 times its value, does so only 22 times when in the ortho-position in the benzene nucleus. For this discrepancy the explanation offers itself, on the one hand, that the system of carbon atoms which constitutes the benzene nucleus is not rigid, but alters its form according to the atoms present in it, and that if so, the difference in form must be especially great according as hydroxyl or chlorine enters near the carboxyl. On the other hand, the following possibility strikes us. According to the hypothesis of Kekulé, there are two sorts of ortho- positions, the one being represented by a double, the other by a single, linkage. Now it is quite possible that in benzene itself the change of the double or single linking to the right or the left takes place easily, but that when two adjoining carbon atoms have fixed different atoms or groups of atoms, only one sort of linkage, either a single one or a double one, is stable. Assuming that—in salicylic acid, for instance—double linkage exists between the carbon atoms, combined with carboxyl and hydroxyl respectively,  while in *o*-chlorobenzoic acid the single linkage only is stable,  , the difference emphasised above can be understood, since in the first case the ortho- relation is a much more intimate one than in the second.

The small changes which the constant of benzoic acid undergoes in *m*- and *p*-chlorobenzoic acid correspond to the greater distance of the chlorine from the carboxyl. According to the usual representation of benzene, the influence of the para- position proves to be the smallest. But this behaviour is by no means general.

Bromine behaves very similarly to chlorine. The effect for the ortho- position is somewhat larger than for chlorine—*i.e.* 24 instead of 22; that for the meta- position somewhat smaller—2·3 instead of 2·6.

When hydrogen in gallic acid is replaced by bromine in the ortho- position, the constant increases to 15 times its value, therefore less than in the case of benzoic acid. This corresponds to the general rule that several substituents simultaneously present diminish each other's action. Only when two substituents, which are the same, occupy the ortho- position is an increase in the simultaneous effect to be observed; in fact, a second bromine atom which occupies the ortho- position brings about a greater rise of the constant than does the first—21 instead of 15.

Hydrofluoric acid being much weaker than hydrochloric acid, it was to be expected that the fluobenzoic acids would be weaker than the chlorobenzoic acids. In case of the meta- compound this occurs, however, only to a small extent; the constants differ but little, and are nearly the same for the bromo- and fluo- compounds. It would be of interest to determine whether in the ortho- position also fluorine acts as strongly as chlorine, but *o*-fluobenzoic acid has not yet been examined; *m*-cyanobenzoic acid is markedly stronger than *m*-chlorobenzoic acid. This completely corresponds to the fact that cyanacetic acid is much stronger than chloracetic acid.

From measurements of the nitrobenzoic acids, the group NO_2 appears to be the most effective negative substituent. The ortho- compound exhibits a 103-fold increase of the constant, the meta- compound an increase equal to 5·8-fold, and the para- compound a 6·7-fold increase. With regard to the influence of position, the numbers agree with those found for the chloro- and bromo- compounds, in so far as the ortho- position is again that of greatest influence; but, on the other hand, the influence of the nitro- group makes itself more felt from the para- position than from the meta- position, in opposition to the relations found in the case of chlorine.

Bromonitrobenzoic acid contains the substituents in the order $CO_2H{:}NO_2{:}Br = 1{:}2{:}5$. The constant is made up of that of benzoic acid, and of the factor of the *o*-nitro- group 103, and that of the *m*-bromine 2·3, and is therefore calculated to be 1·38, which agrees well with 1·4, the value found by experiment. In this case, therefore, the mutual influence of the simultaneously present substituents is practically zero.

The constants of *o*- and *p*- amidobenzoic acid show that the amido- group considerably reduces the strength of the acid. But the values quoted can only be looked upon as approximations, since peculiarities appear in the determinations which are not yet elucidated.

But the numbers become regular when the basic properties of the amido- residue are compensated by the introduction of acetyl. Of the three acetamidobenzoic acids the ortho- compound is the strongest, it surpasses benzoic acid by four times its value. The meta- compound is only 1·4 times as strong as benzoic acid, and in the para- position the atomic group $NHCOCH_3$ acts similarly to hydroxyl—that is, it exerts a weakening effect—the constant is only 0·86 of that of benzoic acid. The acetyl-oxybenzoic acids behave quite similarly; their factors relatively to benzoic acid are 5·5, 1·6 and 0·76. On comparing with these and the former numbers the factors of the oxybenzoic acids—namely, 17, 1·4, and 0·5—it follows that the substituent which in the ortho- position acts most strongly also exerts the greatest weakening influence in the para- position.

But this relation again is not universal. Replacement of hydroxylic hydrogen by methyl in salicylic acid produces a quite extraordinary weakening of the acid; instead of 17 times, the constant is only 1·4 times, as great as that of benzoic acid. In the para- position, however, the same change produces scarcely any effect; the constants of *p*-oxybenzoic acid and of *p*-methoxy-benzoic acid or anisic acid are nearly the same, and the decreasing effect of the group OCH_3 is much greater in the para- than in the ortho- position.

It is further remarkable that acetosalicylic acid is weaker than salicylic acid, in spite of acetyl being a negative radicle. It may be that the cause of this curious behaviour is to be found in a change of linkage similar to that mentioned above.

Homologues of benzoic acid.

o-Toluic acid $C_6H_4(CH_3)CO_2H$	0·012
m-Toluic acid $C_6H_4(CH_3)CO_2H$	0·0051
p-Toluic acid $C_6H_4(CH_3)CO_2H$	0·0052
Phenylacetic acid $C_6H_5.CH_2.CO_2H$	0·0056
Phenylpropionic acid $CH_3.CH(C_6H_5)CO_2H$	0·0043
p-Phenylpropionic acid $CH_2(C_6H_5)CH_2.CO_2H$	0·0023
Cuminic acid $C_6H_4(C_3H_7)CO_2H$	0·0050

A comparison of the constant of benzoic acid with those of the toluic acids shows that a doubling of value has occurred by the introduction of methyl into the ortho- position, but that, as usual, the methyl group in the meta or para- position has a slightly weakening effect. The isomeric phenylacetic acid also has a very similar constant. This constant is 3·1 times greater than that of acetic acid—an indication that phenyl is a negative radicle—but it does not attain to the value of benzoic acid.

The constants for the two phenylpropionic acids show that, as in the case of α- and β- oxypropionic acids, the acid in which the phenyl is at a greater distance from the carboxyl is the weaker. The other relations to be expected are also found; between propionic acid and α-phenylpropionic acid there is the same ratio of the constants, 3·1, as between acetic and phenylacetic acid.

Cuminic acid differs from *p*-toluic acid only in that it contains isopropyl instead of methyl. To this small difference in constitution corresponds as small a difference in the constants.

Hydroxylised homologues of benzoic acid.

Mandelic acid $C_6H_5.CH(OH)CO_2H$	0·0417
Phenoxy-acetic acid $C_6H_5O.CH_2.CO_2H$	0·0756
o-Nitrophenylglycollic acid $C_6H_4(NO_2)O.CH_2.CO_2H$	0·158
p-Nitrophenylglycollic acid $C_6H_4(NO_2)O.CH_2.CO_2H$	0·153
Tropic acid $CH_2(OH).CH(C_6H_5)CO_2H$	0·0075
Phloretic acid $CH_3CH(C_6H_4.OH)CO_2H$	0·0020
Hydroparacoumaric acid $CH_2(C_6H_4.OH)CH_2.CO_2H$	0·0017

Mandelic acid is phenylated oxyacetic acid; the ratio of its constant to that of glycollic acid is 2·7, while that between acetic acid and phenylacetic acid is 3·1; both values approximate closely to each other.

On introducing into the phenyl of phenoxyacetic acid a nitro- group in the ortho- position, the constant rises to double its value. The introduction of NO_2 in the ortho- position into benzoic acid raises the constant to 103 times its former value. This enormous difference exemplifies most prominently the influence exerted by the varying distance of the substituent from the carboxyl. The same thing is made evident by the constant of *p*-nitrophenylglycollic acid, which is scarcely different from that of the ortho- compound; the change from the ortho- to para- position, which is generally so influential, is of scarcely any account at this distance from the carboxyl.

Tropic acid is α-phenyl-β-oxypropionic acid. It is 2·5 times stronger than oxypropionic acid. For the influence of phenyl in the α- position we have before found the factors 2·7 and 3·1.

Phloretic acid is phenylpropionic acid whose phenyl contains a hydroxyl in the para- position; its constant is half as great as that of phenylpropionic acid; hence the para- hydroxyl here exerts its characteristic weakening effect.

In the same way hydroparacoumaric is hydrocinnamic acid which contains a para-hydroxyl in the phenyl. This also has a decreasing action on the constant, but owing to the greater distance of the phenyl this effect is not so great as in the preceding case.

Unsaturated acids. The affinity co-efficients of these substances present a special interest owing to their isomeric relations, which cannot be represented by the ordinary chemical formulæ. Following up an idea of van't Hoff, an explanation of these phenomena has lately been given by Wislicenus (*Abh. König. Sächs. Ges. der Wiss.* 1887). In this explanation the cause of the chemical differences is supposed to lie in differences in the relative positions in space of the radicles linked to the carbon. Since the results so far obtained from a consideration of the affinity-constants invariably point to relations in space, it becomes possible to subject this hypothesis to an experimental examination.

Acrylic acid $CH_2:CH.CO_2H$	0·0056
Crotonic acid $CH(CH_3):CH.CO_2H$	0·00204
Isocrotonic acid $CH(CH_3):CH.CO_2H$	0·0036
Tiglic acid $CH(CH_3):C(CH_3)CO_2H$	0·00096
Angelic acid $CH(CH_3):C(CH_3)CO_2H$	0·0050
α-Chlorocrotonic acid $CH(CH_3):CCl.CO_2H$	0·0720
allo-α-Chlorocrotonic acid $CH(CH_3):CCl.CO_2H$	0·158
β-Chlorocrotonic acid $CCl.(CH_3):CH.CO_2H$	0·0144
allo-β-Chlorocrotonic acid $CCl.(CH_3):CH.CO_2H$	0·0095

A consideration of these numbers shows that the unsaturated acids have in general greater constants than the saturated ones. We must, therefore, ascribe to hydrogen a strongly basic character. And, further, as in the case of the saturated fatty acids, the constants on the whole decrease as the carbon increases. And, finally, we see that the isomeric acids for which, according to the views hitherto held, no difference of constitution could be formulated are in fact distinctly different.

Now Wislicenus represents the difference between crotonic acid and isocrotonic acid by the following formulæ :—

Crotonic acid

$\begin{matrix}\mathrm{H}\\ \mathrm{H}\end{matrix}\!>\!\mathrm{C{=}C}\!<\!\begin{matrix}\mathrm{CH_3}\\ \mathrm{CO_2H}\end{matrix}$

and

Isocrotonic acid

$\begin{matrix}\mathrm{CH_3}\\ \mathrm{H}\end{matrix}\!>\!\mathrm{C{=}C}\!<\!\begin{matrix}\mathrm{H}\\ \mathrm{CO_2H}\end{matrix}$

In crotonic acid the methyl group stands nearer to the carboxyl, in isocrotonic acid the hydrogen. Since, in accordance with present experience, a methyl group linked to carbon which is also directly linked to CO_2H decreases the constant, a smaller constant must be expected for crotonic acid than for isocrotonic, this difference being more pronounced owing to greater proximity in space. Experiment confirms this conclusion, and thus proves the appropriateness of Wislicenus' assumption.

It may be asked whether we are not here dealing with one of the cases of which some were mentioned before, in which, as an exceptional case, the methyl acts by increasing the strength. But this view is excluded, since both acids are weaker than acrylic acid. Methyl has, therefore, in both cases reduced the strength, but to a greater degree in crotonic than in the iso- acid.

Wislicenus assumes similar differences in constitution for angelic and tiglic acids. We get

Angelic acid

$\begin{matrix}\mathrm{CH_3}\\ \mathrm{CH_3}\end{matrix}\!>\!\mathrm{C{=}C}\!<\!\begin{matrix}\mathrm{CO_2H}\\ \mathrm{H}\end{matrix}$

and

Tiglic acid

$\begin{matrix}\mathrm{CH_3}\\ \mathrm{H}\end{matrix}\!>\!\mathrm{C{=}C}\!<\!\begin{matrix}\mathrm{CO_2H}\\ \mathrm{CH_3}\end{matrix}$

Hence angelic acid again would have to be stronger than tiglic, as has been verified by experience. But it is remarkable that in this case the difference has been found to be much greater than in the first one. Angelic acid has a greater constant than isocrotonic acid, which contains CH_2 less than angelic acid, a fact as unusual as that tiglic acid exhibits a smaller constant than the corresponding saturated acid, valeric, which has for constant 0·00161.

In the same way the values found for the α-chlorocrotonic acids agree with experience. The constants are very nearly in the same ratio as that of those of the two crotonic acids themselves, and the rise effected by the chlorine introduced into the α- position is represented by the factors 36 and 44, which, though markedly smaller, are of the same order of magnitude as the factor for monochloracetic acid.

In opposition to the agreement holding hitherto between theory and experiment, in the case of the β-chlorocrotonic acids, the *allo*- compound proves distinctly weaker than the derivative of crotonic acid. The cause of this discrepancy cannot yet be established. The ratio of the constants for crotonic acid and β-chlorocrotonic acid is 1:7, which is nearly the same as the corresponding factor for propionic acid and β-iodopropionic acid, viz. 6·6. On the other hand, the ratio for the factors of isocrotonic acid and the *allo*-β-chloro- derivative is 1:2·6, and is, therefore, much smaller.

Tetrolic acid is formed from both β-chlorocrotonic acids by splitting off hydrochloric acid; the constant is

Tetrolic acid $CH_3.C{:}C.CO_2H$ . . . 0·246

Though hydrochloric acid is one of the strongest acids, yet the splitting off of its elements from the β-chlorocrotonic acids not only has not lowered the constant, but has raised it considerably. This result makes evident the strongly acid nature of carbon and the basic nature of hydrogen; the removal of four hydrogen atoms from butyric acid, whose constant is 0·00149, has produced a rise in the constant of 160 times its value.

Of other unsaturated acids the following have been measured—

Hydrosorbic acid $C_5H_9.CO_2H$	0·00241
Sorbic acid $C_5H_7.CO_2H$	0·00173
Parasorbic acid $C_5H_7.CO_2H$	0·00173
Ethyl-methacrylic acid $C_5H_9.CO_2H$	0·00111
Atropic acid $CH_2{:}C(C_6H_5)CO_2H$	0·0143
Cinnamic acid $CH(C_6H_5){:}CH.CO_2H$	0·00355
Isocinnamic acid $CH(C_6H_5){:}CH.CO_2H$	0·0156
p-Coumaric acid $CH(C_6H_4.OH){:}CH.CO_2H$	0·0022
o-Coumaric acid $CH(C_6H_4.OH){:}CH.CO_2H$	0·0021
Umbellic acid $CH(C_6H_3(OH)_2){:}CH.CO_2H$	0·00188
α-Bromo-cinnamic acid $CH(C_6H_5){:}CBr.CO_2H$	1·44
β-Bromo-cinnamic acid $CH(C_6H_5){:}CBr.CO_2H$	0·093
Phenylpropiolic acid $C_6H_5.C{:}C.CO_2H$	0·59
o-Nitro-phenylpropiolic acid $C_6H_4NO_2.C{:}C.CO_2H$	1·06

In accordance with the general rule, hydrosorbic acid is stronger than the corresponding saturated compound, which is caproic acid ($k = 0·00145$), while sorbic acid, which contains 2H less, is not stronger but weaker than hydrosorbic acid. It is, therefore, probable that sorbic acid has not one treble linkage, but two double ones, or it may have an altogether different constitution, perhaps one with a closed chain arrangement of the carbon atoms.

Sorbic acid is sometimes obtained in the form of an oil which only when treated with acids or alkalis passes into the crystalline acid. Since it did not seem impossible that this was a case of isomerism, such as that of crotonic and isocrotonic acid, the constant of the liquid parasorbic acid was also measured. It proved identical with that of sorbic acid, and hence, with Fittig and Baringer (*A.* 161, 325 [1871]), these substances must be considered, not as isomeric, but as chemically identical.

The constant of methylethylacrylic acid is remarkably small; it is smaller than that of the saturated fatty acid, and approaches that of tiglic acid. The acids α-phenylacrylic, or atropic, and β-phenylacrylic or cinnamic, behave as we should expect; the phenyl group causes a much higher value of the constant when it is in the α- than when it is in the β- position. But it is remarkable that cinnamic acid is not only weaker than atropic acid, but even weaker than acrylic acid; in this case, then, the phenyl group lowers the constant.

In the case of cinnamic acid, two 'geometrically isomeric' compounds may be expected, namely—

$\begin{matrix}\mathrm{H}\\ \mathrm{C_6H_5}\end{matrix}\!>\!\mathrm{C{=}C}\!<\!\begin{matrix}\mathrm{CO_2H}\\ \mathrm{H}\end{matrix}$

and

$\begin{matrix}\mathrm{H}\\ \mathrm{H}\end{matrix}\!>\!\mathrm{C{=}C}\!<\!\begin{matrix}\mathrm{CO_2H}\\ \mathrm{C_6H_5}\end{matrix}$

Quite recently there has been discovered by Liebermann a second cinnamic acid which must be regarded as geometrically isomeric with the ordinary one; it has a much higher constant than the latter, and hence we may conclude that in the new isocinnamic acid the negative phenyl has a closer connexion with the carboxyl than in the old one, and that the new acid may have the second of the above formulæ.

Similarly, there are known two isomeric bromocinnamic acids, which are produced from cinnamic acid dibromide by splitting off hydrobromic acid, and for which the same kind of isomerism holds. Nor can there be any doubt as to which acid corresponds to each formula, the differences in the constants being very great, and in fact it has been made known quite recently by Erlenmeyer that he has obtained Liebermann's isocinnamic acid from the stronger *α*-bromocinnamic acid.

The phenylpropiolic acid formed from the bromoinnamic acids by splitting off hydrobromic acid, is stronger than the *β*- compound, but weaker than the isomeric *α*- compound. The constant is also, as was to be expected, greater than that of tetrolic acid. In *o*-nitro-phenylpropiolic acid the nitro- group in the ortho-position has again been able to exert but a slightly strengthening action, owing to its being at a great distance from the carboxyl.

On comparing cinnamic acid with *p*-coumaric acid, we find that the hydroxyl introduced into the *p*- position again lowers the constant. But, strange to say, a similar effect is produced in the derivatives of cinnamic acid by hydroxyl in the ortho- position; *o*-coumaric acid is also weaker than cinnamic acid. It is in accordance with this that umbellic acid, which contains one hydroxyl in the ortho- position and a second one in the para- position, is weaker than all these acids. It is to be expected that these relations will prove of importance for the complete elucidation of the constitution of these remarkable compounds.

Dibasic acids. The acids of the oxalic series gave the following constants:

Oxalic acid $(CO_2H)_2$	10(?)
Malonic acid $CH_2(CO_2H)_2$	0·158
Succinic acid $C_2H_4(CO_2H)_2$	0·0066
Pyrotartaric acid $C_3H_6(CO_2H)_2$	0·0048
Adipic acid $C_4H_8(CO_2H)_2$	0·0037
Pimelic acid $C_5H_{10}(CO_2H)_2$	0·0036
Suberic acid $C_6H_{12}(CO_2H)_2$	0·0026
Sebacic acid $C_8H_{16}(CO_2H)_2$	0·0023

It has already been explained that the weaker dibasic acids H_2R'' split electrolytically according to the scheme $H + HR''$, and that therefore constants may be calculated for these acids in a manner analogous to that adopted for the monobasic acids. In the case of oxalic acid, however, this is not possible, since the dissociation has proceeded too far; the constant is only estimated approximately, but beginning from malonic acid, the values of the constants can be very well determined.

We see that at first the constants decrease very rapidly; that of malonic acid is about 60 times smaller than that of oxalic acid. From malonic to succinic acid the step is much smaller, 24 : 1, and much smaller from the latter to pyrotartaric acid, 1·4 : 1, and henceforward the numbers vary only by small amounts. The influence which one carboxyl group exerts on the hydrogen of the other decreases, therefore, very rapidly in consequence of the interposition of the carbon atoms; sebacic acid does not surpass by more than twice the fatty acids richer in carbon. Of the numerous isomerides with side carbon chains, the following have been measured:

Methylmalonic acid $CH(CH_3)CO_2H$	0·087
Ethylmalonic acid $CH(C_2H_5)CO_2H$	0·127
Dimethylmalonic acid $C(CH_3)_2CO_2H$	0·077
Methylsuccinic acid $C_2H_3(CH_3)CO_2H$	0·0086
α-Dimethylsuccinic acid $C_2H_2(CH_3)_2CO_2H$	0·0343
β-Dimethylsuccinic acid $C_2H_2(CH_3)_2CO_2H$	0·0245

The three first acids appear at once to be derivatives of malonic acid; their constants do not differ much from that of their parent substance, but all are somewhat smaller. Similarly, the constants of the derivatives of succinic acid approach to the value of the latter, but are all greater. The alcoholic groups have therefore acted in these cases in the ordinary way: an explanation of this has been attempted by Bethmann (*Z. P. C.* 5, 407).

Derivatives of oxalic and of malonic acid:—

Oxamic acid $CO.NH_2.CO_2H$	0·80
Oxaluric acid $CO(NH.CO.NH_2)CO_2H$	4·5
Oxanilic acid $CO(NHC_6H_5)CO_2H$	1·21
o-Chloro-oxanilic acid $CO(NHC_6H_4Cl)CO_2H$	2·03
p-Chloro-oxanilic acid $CO(NHC_6H_4Cl)CO_2H$	1·40
p-Tolyl-oxamic acid $CO(NHC_7H_7)CO_2H$	0·88

The amido- group entering into one of the carboxyls of oxalic acid causes a weakening of the acid to one-twelfth its value; the much more weakly basic urea residue produces a much smaller weakening effect, *viz.* to about half the value. The decrease caused by the residue of aniline is smaller also, to about the eighth part; when chlorine enters into the phenyl of the latter, there again occurs an increase in the acid properties, which increase, however, in consequence of the greater distance, is much smaller than in benzoic acid. But a distinct difference between the ortho- and the para- position still asserts itself. Methyl in the para- position exerts a distinctly weakening effect.

Tartronic acid $CH(OH)(CO_2H)_2$	0·107
Phenylmalonic acid $(C_6H_5)_2C:(CO_2H)_2$	0·408
Malonanilic acid $CH_2CO(NHC_6H_5)CO_2H$	0·0196

Strange to say, in spite of the hydroxyl, tartronic acid is weaker than malonic acid ($k = 0·158$). The replacement of both hydrogen atoms of malonic acid by benzylic radicles raises the constant. Finally, malonanilic acid is about eight times weaker than the parent substance.

Derivatives of succinic acid.

Malic acid $C_2H_3(OH)(CO_2H)_2$	0·0395
Inactive malic acid $C_2H_3(OH)(CO_2H)_2$	0·0399
Dextrotartaric acid $C_2H_2(OH)_2(CO_2H)_2$	0·097
Lævotartaric acid $C_2H_2(OH)_2(CO_2H)_2$	0·097
Racemic acid $C_2H_2(OH)_2(CO_2H)_2$	0·097
Mesotartaric acid $C_2H_2(OH)_2(CO_2H)_2$	0·060
Phenyl-succinamic acid $C_2H_4(CONHC_6H_5)CO_2H$	0·0020

o-Chlorophenylsuccinamic acid $C_2H_4(CONHC_6H_4Cl)CO_2H$.	0·0021
***m*-Chlorophenylsuccinamic** acid $C_2H_4(CONHC_6H_4Cl)CO_2H$.	0·0021
p-Chlorophenylsuccinamic acid $C_2H_4(CONHC_6H_4Cl)CO_2H$.	0·0021
o-Tolyl-succinamic acid $C_2H_4(CONHC_7H_7)CO_2H$ . .	0·0021
p-Tolyl-succinamic acid $C_2H_4(CONHC_7H_7)CO_2H$ . .	0·0020
Succinuric acid $C_2H_4(CONHCONH_2)CO_2H$.	0·00311
Thio-succinuric acid $C_2H_4(CONHCSNH_2)CO_2H$.	0·00333

Oxysuccinic, or malic, acid has a constant six times as great as succinic acid. The factor is somewhat smaller than for the monobasic acids, which may be because a negative radicle carboxyl is already present. The natural optically active acid has exactly the same constant as the inactive acid got from monobromsuccinic acid. The same relation recurs in tartaric acid and racemic acid. Both the dextrorotatory and the lævorotatory acid, as also the inactive racemic acid formed by a combination of these two, are all of exactly the same strength. This result is in accordance with the present views concerning the constitution of these compounds. The dextrorotatory and lævorotatory acids contain their constituents in a perfectly symmetrical arrangement, and must, therefore, have equal co-efficients of affinity. It has been assumed that the optically inactive acids produced from the optically rotating ones consist each of two molecules of the active acids. This is probably correct for the solid crystallised substances, but not for solutions; in these, both compounds are present side by side, uncombined, a conclusion which has also been arrived at in another way by Perkin (*C. J.* 52, 362). The undecomposable inactive mesotartaric acid has, however, another, and that a smaller, constant; theory also ascribes to it a different constitution.

In the preceding table are further contained a number of derivatives of phenylsuccinamic or succinanilic acid. This acid itself is only 3·3 times weaker than succinic acid, while the introduction of the aniline residue into CO_2H of malonic acid decreased the strength 8 times; this indicates that the position of the substituent at a greater distance weakens the effect. The almost complete equality of the constants for all substitution products of succinanilic acid is of great interest; the distance of the benzylic residue from the carboxyl is here too great to allow the substituents to exert their effect over it. The usual assumption, that the molecular forces cease to act at even very small distances, is thereby made more definite, in that such distances are already given by the molecular dimensions.

As already found, the introduction of the urea residue produces a smaller decrease than that due to aniline. Smaller still is the effect of the thio-urea residue.

Dicarboxylic acids of benzene.

o-Phthalic acid $C_6H_4(CO_2H)_2$ . .	0·121
m-Phthalic acid $C_6H_4(CO_2H)_2$ . .	0·0287
Oxyterephthalic acid $C_6H_3.OH.(CO_2H)_2$	0·25
Phthalamic acid $C_6H_4(CONH_2)CO_2H$.	0·0160
Phthaluric acid $C_6H_4(CON_2H_3CO)CO_2H$	0·0290

As we were led to expect, the entry of a carboxyl in the ortho- position produces a somewhat considerable rise in the constant—*viz.* to twenty times the former value. For the meta-position the factor is only 4·8. *p*-Phthalic acid is too insoluble to be measured. But assuming that in oxy-*p*-phthalic acid the hydroxyl acts as strongly as in salicylic acid, the constant of *p*-phthalic acid would be estimated as 0·014 to 0·015, and it would follow that, in accordance with the usual result, carboxyl in the para- position—*i.e.* in the distant one—exerts the least action. A *weakening* effect, such as is exerted by hydroxyl in the para- position, seems to be excluded.

The amide residue in phthalamic acid has lowered the constant to one-eighth its value, but the acid is yet stronger than benzoic acid, and the group $CONH_2$ must be looked upon as negative. The urea residue exerts, as it always does, a much less marked weakening effect.

Unsaturated dibasic acids. The dicarboxylic acids $CH_{2n-2}(COOH)_2$ exhibit very similar isomeric relations to those of the compounds of the acrylic acid series. The following were measured:—

Maleic acid $C_2H_2(CO_2H)_2$ . . .	0·17
Fumaric acid $C_2H_2(CO_2H)_2$ . . .	0·093
Citraconic acid $C_3H_4(CO_2H)_2$ . . .	0·340
Mesaconic acid $C_3H_4(CO_2H)_2$ . .	0·079
Itaconic acid $C_3H_4(CO_2H)_2$ . . .	0·0120

The isomeric compounds are seen to have widely different constants. These results agree very well with the views of van't Hoff and Wislicenus. For fumaric and maleic acids the following formulæ have been adopted:

Maleic acid

Fumaric acid

According to this, the two carboxyl groups are much nearer to each other in maleic than in fumaric acid, and the first must be stronger, as is actually the case. Similarly, according to Wislicenus, the formulæ

Citraconic acid

Mesaconic acid

hold, and for the same reason citraconic acid must be stronger than mesaconic acid, which conclusion again agrees with experiment.

Itaconic acid has the formula  $\begin{array}{l} CH_2:C—CO_2H \\ \quad\;\; | \\ H_2C—CO_2H \end{array}$ and therefore no double linkage between the carbon atoms combined with carboxyl. Accordingly, its constant is much smaller; it is only twice as great as that of succinic acid.

It may be mentioned that acetylene dicarboxylic acid  $\begin{array}{l} C—CO_2H \\ C—CO_2H \end{array}$ is so strong that a constant cannot be determined for the first stage of dissociation. The acid is but little inferior to sulphuric acid.

Thiophene and pyridine group.

α-Thiophenic acid $C_4H_3S.CO_2H$ . .	0·030
Pyromucic acid $C_4H_3O.CO_2H$ . .	0·071
Picolinic acid (α) $C_5H_4N.CO_2H$ . .	0·0003
Nicotinic acid (β) $C_5H_4N.CO_2H$ . .	0·00137
Isonicotinic acid (γ) $C_5H_4N.CO_2H$.	0·00109

Lutidinic acid ($\alpha\gamma$) $C_5H_3N.(CO_2H)_2$	0·60
Cinchomeronic acid ($\beta\gamma$) $C_5H_3N.(CO_2H)_2$	0·21
Isocinchomeronic acid ($\alpha\beta$) $C_5H_3N.(CO_2H)_2$	0·43
Chinolinic acid ($\alpha\beta$) $C_5H_3N.(CO_2H)_2$	0·30
$\beta\beta$-Pyridine dicarboxylic acid $C_5H_3N.(CO_2H)_2$	0·15

The replacement of the group C_2H_2 in benzoic acid by sulphur raises the constant to five times its value, provided the carboxyl is placed next to the sulphur. In the β- position the carboxyl is without doubt influenced less, but we have yet no measurement of the constant.

It is remarkable that a similar replacement of C_2H_2 by oxygen, forming pyromucic acid, acts much more strongly than a replacement by sulphur. On account of the magnitude of the constant it is very probable that in pyromucic acid the carboxyl is in a position next to the oxygen.

Differently from sulphur and oxygen, the replacement of C_2H_2 by CNH has a strongly weakening effect on the constant. The values found for the monocarboxylic acids of pyridine correspond fairly with the assumptions which might be made on the basis of the constitutions of these substances; picolinic acid, which contains the carboxyl next to the nitrogen, is by far the weakest; but the β- acid is stronger than the γ- compound, so that in pyridine the β- position proves the place of smallest influence.

The behaviour of the dicarboxylic acids of pyridine is very unexpected. While all monocarboxylic acids of pyridine are weaker than benzoic acid, all dicarboxylic acids are stronger than the strongest dicarboxylic acid of benzene—that is, o-phthalic acid, whose constant is 0·12. A further difference is that the strongest dicarboxylic acids are those which contain carboxyl in the α- position—that is, next to the nitrogen. Then follow the acids which contain carboxyl in the γ- position, and lastly those with carboxyl in the β- position. These relations are the exact reverse of those observed for the monocarboxylic acids; where a decrease of the constant had been observed there, an increase is found here. No plausible hypothesis concerning the cause of these peculiar phenomena has yet been brought forward.

Oxycinchomeronic acid $C_5H_2(OH)^{\alpha}N.(CO_2H)_2$	1·67
Methyl pyridine dicarboxylic acid $C_5H_2(CH_3)^{\alpha}N.(CO_2H)_2^{\beta\beta}$	0·20
Dimethyl pyridine dicarboxylic acid $C_5H(CH_3)_2^{\alpha\alpha}N(CO_2H)_2^{\beta\beta'}$	0·34
Dimethyl pyridine dicarboxylic acid $C_5H(CH_3)_2^{\alpha\gamma}N.(CO_2H)_2^{\beta\beta'}$	0·55

Owing to the entry of hydroxyl in the ortho-position, cinchomeronic acid has had its constant increased to eight times its value. The methyl groups increase the strength of the $\beta\beta$-dicarboxylic acid, and they do so to a greater extent in the γ- position than in the α- position.

Further, several poly-carboxylic acids of pyridine were examined; the constants cannot, however, be calculated, because the dissociation assumes a somewhat complicated character. But it is evident that the relations found in the case of the dicarboxylic acids concerning the influence of the position of the carboxyl hold good in these cases also. The rules found for the dicarboxylic acids were also confirmed in the case of methyl derivatives of the tricarboxylic acids. On the other hand, phenyl on entering into lutidine dicarboxylic acid, whose constant is 0·34, has a weakening effect, the constant for the compound formed being only 0·012. The action here is the reverse of that observed in the case of the fatty acids.

Quinaldinic acid $C_9H_6N.CO_2H$	0·0012
Cinchonic acid $C_9H_6N.CO_2H$	0·0013
Dipyridyl monocarboxylic acid $C_{10}H_7N_2.CO_2H$	0·002
Dipyridyl dicarboxylic acid $C_{10}H_6N_2(CO_2H)_2$	0·032
o-Pyridine benzoic acid $C_{11}H_8N.CO_2H$	0·0005
Phenyl pyridine dicarboxylic acid $C_{11}H_7N.(CO_2H)_2$	0·011

The quinoline carboxylic acids, which have a constitution analogous to that of the pyridine carboxylic acids, are somewhat stronger than these, as the naphthoic acids are stronger than the benzoic acids. Concerning the other acids but little can be generalised.

Amidobenzene sulphonic acids and similar compounds.

o-Amidobenzene sulphonic acid $C_6H_4.NH_2.SO_3H$	0·330
m-Amidobenzene sulphonic acid $C_6H_4.NH_2.SO_3H$	0·0185
p-Amidobenzene sulphonic acid $C_6H_4.NH_2.SO_3H$	0·0581

The results obtained from measurements of the amidobenzene sulphonic acids are somewhat remarkable. While benzene sulphonic acid itself is so strong an acid that its dissociation constant cannot be determined, its amido- derivatives can be measured with ease; the amido- group has, therefore, as it usually does, exerted a weakening effect. But in the case of the carboxylic acids the ortho- position was always that of greatest influence; here it appears as the position of least influence. The weakest of the three acids is the meta- compound, then follows the para- compound, and then the ortho- compound, which comes nearest to the parent substance. The assumption is thus suggested that, by the agency of the group SO_2, the hydrogen is brought to such a distance from the benzene nucleus that it is more influenced by the radicles in the meta- position than by those in the ortho-position.

Diamidobenzene sulphonic acid (2,3) $C_6H_3(NH_2)_2SO_3H$	0·0050
Bromamidobenzene sulphonic acid (2,5) $C_6H_3BrNH_2SO_3H$	7·9
Bromamidobenzene sulphonic acid (3,6) $C_6H_3BrNH_2SO_3H$	0·072
Dibromamidobenzene sulphonic acid (3,4,6) $C_6H_2Br_2NH_2SO_3H$	2·5
Toluidine sulphonic acid (3,4) $C_6H_3(CH_3)NH_2SO_3H$	0·024
Xylidene sulphonic acid (4,2,5) $C_6H_2(CH_3)_2NH_2SO_3H$	0·044

In indicating the constitution, the sulpho- group is put = 1, then follows amide, and then bromine or methyl.

These acids exhibit the usual relations to be expected from the nature of the substituents and their position, and thus do not call for any detailed discussion.

General considerations. The properties of chemical compounds, which can be expressed numerically, may be divided into three groups—the additive, the cumulative, and the constitutive. The first are of such a nature that in chemical compounds their value is the sum of the corresponding values of the constituents; these values have led to the conception of the atomic theory—*i.e.* to the assumption that the components continue to exist in the compounds as such.

The cumulative properties exhibit the peculiarity that, independently of the number and nature of the constituents, their numerical value is the same for certain complex systems. These have led to the conception of the molecular theory—*i.e.* to the assumption that the components of chemical compounds primarily form similar groups or systems, which have an individual existence, and out of which the visible and ponderable substances are built up.

And, finally, there exists a third group of properties, which are neither additive nor cumulative, since even in the case of substances having the same composition they can assume different values. These have led to the assumption that, in addition to the nature and number of the composing atoms, the properties of substances are influenced by still another condition. This condition has, from the time of Berzelius, been considered to lie in the different arrangement of the atoms within the molecule—*i.e.* in the constitution.

Of all the constitutive properties hitherto known—such as boiling-point, melting-point, colour, crystalline form, &c.—not one affords a clear insight into the determining cause, the chemical constitution. It is possible, when the latter has been found, more or less approximately, by purely chemical methods, to establish empirical relations; but these lie on the surface only, and lack generality. The cause of this is the defective development of our conceptions concerning the kind and the amount of the influence which the arrangement of the elementary atoms in the molecule exerts on the properties mentioned.

I believe I am not deluding myself when I affirm that the affinity constants, which represent a property of eminently constitutive nature, are far superior to all others with respect to their theoretical applicability. The result that one and the same atom exerts quite different effects, according to the 'position' which it occupies in the molecule, and that these effects are the greater the more close is the relation of the atom to that of the acid hydrogen, leads to the general inference that these effects are functions of the distance in space of the atoms in question. But thereby, for the first time, is gained a means of taking measurements in space of molecular structures. There is no doubt that long and laborious work is needed before such measurements will lead to results which will give an all-sufficient representation of the form of molecules. But it already seems certain that this goal can be reached.

It has been mentioned, to start with, that k, the affinity co-efficient of acids, appears, generally speaking, as a product whose factors are given by the nature and position of the elementary atoms composing the acid. This follows from the fact that with analogous changes in analogous substances the constants change in the same ratio—*i.e.* that in consequence of these changes the constants of the original substances must be multiplied by the same factor. But these factors are never exactly the same, just because two analogous changes are never exactly the same. If, for instance, we change acetic acid into glycollic acid, and propionic acid into lactic acid, the two changes are, it is true, very much alike; but in the first case the hydroxyl takes up a position next to two hydrogen atoms, in the second case next to one hydrogen atom and one methyl; the hydroxyl is therefore subject to a different influence, and will in consequence necessarily act differently on the carboxyl. The same holds for all corresponding cases. The approximate character of the general relation follows, therefore, as a necessity; the deviations from the type are caused by the nature of the subject, and themselves afford a means for bringing to light their cause, which is the secondary influence mentioned above. What has been said concerning the constitutive properties generally—that they can never be completely represented by a general scheme, because this is contradictory to their nature—holds particularly for the affinity co-efficients. In them the whole variety of nature asserts itself, and within the framework of great and general regularities produces the finest individualisation.

The form of the dissociation-constant as the product of factors $c = c_1.c_2.c_3$ . . . . has a deeper significance, which is recognised on going back to the dissociation-formula itself. This formula is obtained from the mechanical theory of heat in the following form:

$$\log.\frac{p}{p_1 p_2} = \frac{\rho}{R\tau} + C$$

where p_1 and p_2 are the partial pressures of the products of decomposition, p the pressure of the undecomposed substance, ρ the heat of dissociation, τ the absolute temperature, R the gaseous constant, and C is a value which is a function of the temperature only, and which, therefore, at constant temperature can be looked upon as a constant.

In the case in point $p_1 = p_2$, and since p_1 and p must be put proportional to $\frac{m}{v}$ and $\frac{1-m}{v}$, it follows that $\frac{p}{p_1^2} = \frac{(1-m)v}{m^2}$ and thence

$$\log.\frac{(1-m)v}{m^2} = \frac{\rho}{R\tau} + C$$

or

$$\log.\frac{m^2}{(1-m)v} = -\frac{\rho}{R\tau} + C^1.$$

Now the affinity co-efficient is $k = \frac{m^2}{(1-m)v}$; and since, on the other hand, quite generally $k = k_1.k_2.k_3$ . . . . it follows that

$$\log.k_1 + \log.k_2 + \log.k_3 + \ldots\ldots = -\frac{\rho}{R\tau} + C^1.$$

The constant C^1 depends only on the unit adopted and on the point chosen as zero; if, therefore, there appears on the left side of the equation a sum of terms represented by log.k, there must correspond to each of these on the right side a term of the form $-\frac{\rho_n}{R\tau}$, so that $\frac{\rho}{R\tau}$ also resolves itself into a sum of corresponding terms $-\frac{1}{R\tau}(\rho_1+\rho_2+\rho_3+\ \ldots\ .)$ in which one R_n and one ρ_n always correspond to each other.

This means: The natural logarithm of the dissociation-constant or affinity-constant is (save for a constant) proportional to the heat of dissociation of the acid in splitting into ions. Since the value of the dissociation- or affinity-constant is known from experiment to be the sum of a series of terms which depend on the nature and on the position of the constituent atoms, it follows that the electrolytic heat of dissociation also is the sum of a corresponding number of terms each of which is fixed by the nature and position of each individual atom.

Now in this case the heats of dissociation are the exact measures of the quantities of work which are done in the separation of the acid hydrogen atom from the negative ion. This is so because no external work has to be taken into account, and because the condition of the substances dealt with very closely approaches that of ideal gases. Hence the heat of dissociation measures the potential or the force-function of the atomic system at the corresponding point, and we see that this force-function is the sum of the values which, according to their nature and position, the individual atoms contribute to the total value. And thus elements which, like chlorine, sulphur, &c., raise the constant k, cause a decrease of the heat of dissociation, since log.k and ρ have different signs. The amido group, on the other hand, which decreases the constant, raises the heat of dissociation—*i.e.* it increases the amount of work necessary for splitting off the acid hydrogen.

It is by these considerations that the long-mooted question concerning the connection between chemical affinity and the thermal values of reactions has been decided in principle. In this result we see the eminently constitutive property of affinity-quantities brought back again to the additive form. This has been effected by introducing the influence of constitution, or of position in space, into the terms themselves. A similar development awaits the theory of all constitutive properties, as, in fact, we are forced to conceive the combined action of different elements as the sum of various effects.

Electrical theory of chemical affinity. Elsewhere (Affinity, vol. i. p. 67) the laws of chemical affinity have already been explained. Nothing definite could be stated concerning their cause; but it followed from the close connection which was shown to exist between the co-efficients of chemical reacting power of electrolytes, and the values of the electrical conductivities, that an intimate relation exists between these two properties. The prospect is thus opened of carrying out in an exact form the electro-chemical theory of affinity which was rather conjectured than worked out by Davy and Berzelius.

The new view which affords such a possibility is the common cause underlying electrolytic conduction and chemical reactions as recognised by Arrhenius, *viz.* the existence of free ions. On making the assumption, which is justified by this concordance, that chemical processes betwee electrolytes take place only by the agency of th free ions, the laws of chemical affinity, which have been established empirically, can be deduce so as to be in accordance with experiment. T do this we only further need van't Hoff's theor of solutions, and the theory of the laws of dissociation as deduced for gases (*v.* Dissociation in vol. ii.), which laws, thanks to van't Hoff's theory, can also be applied to substances in solution.

The general law of chemical affinity first recognised is that manifestations of this affinity on the part of a definite substance are expressible by a definite co-efficient, dependent on the temperature and dilution, but independent of the nature of the chemical reaction in which the substance participates.

Now, if the reacting power of a substance in solution depends on the number of dissociated ions which are present, it can be seen at once that the above-mentioned law must of necessity hold good. So, for instance, the state of dissociation of an acid determines the velocity with which it must act on methylacetate, acetamide, marble, &c. The nature of the other substance determines a factor only, which in analogous cases is the same.

Hence we must conclude that all acids, for instance, when completely dissociated are equally strong. The strong inorganic acids HCl, HBr, HI, HNO_3, $HClO_4$ must be classed here, as also the sulpho- acids and similar organic acids. No one of these substances exhibits any of the specific differences discussed in former paragraphs for acids of medium strength. They all exert a nearly equal effect when used in equivalent quantities, and approach the maximum conductivity even at moderate dilutions. At a time when the dissociation theory of electrolytes did not exist, the author of this article vainly tried to obtain from benzene-sulphonic acid, by all the means which make weak acids stronger—such as the introduction of halogens, nitro-groups, &c.—acids stronger than the parent substance, which may itself be ranged side by side with hydrochloric acid. This was not possible; all 'strengtheners' remained in this case ineffective. This remarkable fact shows that it is not its special nature, but its electrical condition, which is determinant for the chemical effect of a substance, especially if that substance be an acid.

The greater the number of the molecules which are split into their positively and negatively charged parts, the stronger is the acid; but any ion, when once present in the separated, electrically charged, condition, is as effective as any other. Here, then, we see that Berzelius' conclusion drawn from false premisses, by means of which he attempted to demonstrate the absurdity of Faraday's law—that then the chemical affinity between the ions of all electrolytes would have to be the same—is perfectly correct. The affinity of the most diverse ions is really the same, because it does not depend on their nature but on their electrical charge, and this, according to Faraday's law, is everywhere the same. What does depend on the nature of the ions is the degree to which they dissociate, and herein alone lies the cause of the differences in the affinity-quantities.

In the arguments used so far, it has been assumed that the state of dissociation of the reacting substances is determined by the volume and the temperature, and that the presence of other substances does not alter the state of the one considered. This case, however, only occurs when there are present either one dissociated substance and nothing but non-electrolytes besides, or when all the dissociated substances present are for all practical purposes completely split up. But as soon as several partly dissociated substances are present, the relations become much more complicated.

It is known from the theory of dissociation that when two gaseous substances are present, and the quantities of these substances vary, the product of their active quantities, or of their concentrations, must be constant, constant temperature being presupposed. If, for instance, a given space is filled with the gaseous products of decomposition of ammonium hydrosulphide, the addition of sulphuretted hydrogen will cause a decrease in the quantity of hydrosulphide dissociated, because on increasing the one factor the other must decrease in the same ratio. The same must evidently hold for electrolytes; on adding to a solution which contains the ions A + B an excess of ions A, the quantity of ions B must decrease until the product of the two quantities has again become equal to its original value. Now, it is not very well possible to add ions A only, but an electrolyte can be added which is also dissociated, and which contains the ions A + B′; if B′ is different from B, the two do not influence each other.

We may now ask how two solutions must be constituted in order that their state of dissociation shall not vary when the solutions are mixed. We have the solutions of the electrolytes A + B and A + B′, which contain a common ion A; let their volumes be v and v'. Then, in accordance with the general law of the equilibrium of dissociation, the following equations will hold:

$$\frac{1-\xi}{v} = k\frac{\xi}{v}\cdot\frac{\xi}{v}$$

$$\frac{1-\xi'}{v'} = k'\frac{\xi'}{v'}\cdot\frac{\xi'}{v'}$$

in which the quantities of the electrolytes originally present are put as equal to 1, and the dissociated portions equal to ξ and ξ' respectively. On mixing the solutions, the volume becomes $v+v'$, the dissociation ratios ξ and ξ' remaining unchanged, as supposed. The quantities of the undissociated portions are $1-\xi$ and $1-\xi'$, but the products $\xi.\xi$ and $\xi'.\xi'$ change into $\xi(\xi+\xi')$ and $\xi'(\xi'+\xi)$, since the ion A common to both substances participates in the equilibrium condition of both. We have, therefore,

$$\frac{1-\xi}{v+v'} = k.\frac{\xi}{v+v'}\cdot\frac{\xi+\xi'}{v+v'}$$

$$\frac{1-\xi'}{v+v'} = k'.\frac{\xi'}{v+v'}\cdot\frac{\xi+\xi'}{v+v'}.$$

On dividing each of these equations into each of the corresponding equations given above, it follows that $\frac{\xi}{\xi'} = \frac{v}{v'}$. Therefore, in order that the state of dissociation should not alter on mixing solutions of two electrolytes which have one ion in common (for instance, two acids), the portions dissociated must be in the ratio of the volumes. Writing the equation in the form $\frac{\xi}{v} = \frac{\xi'}{v'}$, the law can also be expressed in this form: when the concentration of the common ion is the same in both solutions, these do not influence each other.

Arrhenius, to whom we owe these considerations, calls solutions which do not influence each other in the sense just mentioned *isohydric solutions*. Since, in accordance with the above formula, it is only necessary for this that the *concentration* of the common ion in the two solutions should be the same, the ratio of the quantities of the two solutions does not enter into consideration; isohydric solutions can be mixed in all proportions without mutually changing their condition.

If, however, two non-isohydric solutions which contain a common ion are mixed, the process can be represented by saying that the one solution withdraws water from the other until both have become isohydric; then they leave each other uninfluenced. This withdrawal of water occurs in the following manner. First, the total concentration of the solution which loses water increases, and thereby the concentration of the ions increases also. But, owing to this, the state of dissociation changes directly, since, in consequence of the smaller volume, the dissociation decreases, and, therefore, the concentration of the ions increases more slowly than the total concentration. Conversely, the concentration becomes less in the portion which takes up water; but, owing to the increase in dissociation, it does so to a smaller degree than corresponds to the volume change.

Since the relation between the volume and the state of dissociation is known for binary electrolytes (p. 194), a formula can easily be deduced which allows us to calculate the characteristic quantities for a mixture of several electrolytes. But it is generally simpler to proceed by way of successive approximation.

Two solutions which are isohydric with a third must be isohydric with each other; because, in order to be isohydric with the third, there must be in both the same concentration of the common ion as is in the third solution.

These laws were all established empirically by Arrhenius (*W.* 30, 51), and it was only lately that he deduced them theoretically from his theory of dissociation (*Z. P. C.* 2, 284 [1888]). The examination of these relations is best conducted by making measurements of electrical conductivities. Since the conductivity of a compound in solution is proportional to the number of free ions, it can easily be recognised whether two substances with a common ion—two acids, for instance—are isohydric; if the conductivity of the mixture is equal to the sum of the conductivities of the components, the solutions are isohydric; if this is not the case, the two numbers differ from each other more or less. To quote an example: with a phosphoric acid solution, of specific conductivity $l = 225{\cdot}6$, was mixed an equal volume of hydrochloric acid solution $l = 225{\cdot}9$; the mixture gave $2l = 469{\cdot}0$, while the sum of the two values is $451{\cdot}5$; the observed conduc ivity was too great by 17·5. Further, the same phosphoric acid solution mixed with an equal volume of a more dilute hydrochloric acid, $l = 185·1$, gave for the conductivity of the mixture $2l = 407·4$; this is smaller by 3·3 than the sum 410·7. Finally, hydrochloric acid of $l = 168·8$ gave for the mixture $2l = 394·4$, the sum being 394·4; both solutions were isohydric. By such experiments as this Arrhenius arrived at the laws stated above.

It need scarcely be mentioned that any other property of solutions which depends on the molecular condition of the dissolved substance could likewise have been used for determining the relations of isohydricity. The best of these properties would be measurements of the velocities of reaction — for instance, those of the inversion of sugar — these being proportional to the state of dissociation; but the freezing-points, vapour pressures, &c., could also have been used.

So far the only case considered has been that in which the mixed electrolytes contain a common ion. If this is not the case, new phenomena appear, which we will now consider in greater detail. It has already been pointed out that the theory of free ions leads to a view of the processes of the formation and mutual decomposition of salts which is very different from that generally accepted. It has been shown that, neglecting the small undissociated portions, the process of neutralisation between the strong acids and bases consists exclusively in the formation of water from the ions H and OH. The cause why these ions coalesce to form undissociated water lies in the fact that water is an extremely stable compound, which, under ordinary circumstances, is only very slightly split into ions. If, therefore, such ions anywhere appear simultaneously, they combine directly to form undissociated water.

The phenomena take a quite similar course when a strong acid—hydrochloric, for instance—acts on the salt of a weak acid—sodium acetate, for instance. The former solution is almost exclusively composed of ions H and Cl, the latter of ions Na and $CH_3.CO_2$. Since the sodium chloride also is almost completely dissociated when in dilute solution, the ions Na and Cl are already present in the same condition as in sodium chloride solution, and there exists no tendency to the formation of this compound. But, in addition, there are present the ions H and CH_3CO_2, and these cannot exist side by side without for the most part combining. Hence a corresponding quantity of undissociated acetic acid will be formed, as is actually shown by experiment. But while formerly this fact was ascribed to a specially great affinity between the chlorine and the sodium, and the acetic acid was allowed to play a passive part, being supposed to be 'expelled' by the hydrochloric acid, we now see that the entire cause of the process lies in the action of the acetic acid. Owing to the great affinity of its ions, it is formed whenever its ions meet, while the components of the 'strong' reagents, chlorine and sodium, remain perfectly indifferent in the process.

The conditions under which chemical equilibrium is established between four substances, formed by a combination in pairs of two positive and two negative electrolytes, must now be established in a general manner. We assume we have produced four solutions of the substances A_1B_1, A_1B_2, A_2B_1, and A_2B_2, so that those solutions which contain a common ion are isohydric. When this is the case we can, it is true, mix the isohydric solutions in all proportions; but if we mix all four solutions the simple law stated above evidently no more holds, and we must ask in what proportion the mixture must be made in order that no change in the state of dissociation should occur. Let a, b, c, and d be the relative volumes of the four solutions in which this occurs, and let α, β, γ, and δ be the undissociated quantities of the four substances. We can represent the dissociated quantities by ha, hb, hc, and hd, since, in consequence of the assumption made, there must in all cases be equal concentration of the ions. The equations of dissociation of the solutions thus become

$$\frac{\alpha}{a} = k_1\left(\frac{ha}{a}\right)^2 \qquad \frac{\beta}{b} = k_2\left(\frac{hb}{b}\right)^2$$

$$\frac{\gamma}{c} = k_3\left(\frac{hc}{c}\right)^2 \qquad \frac{\delta}{d} = k_4\left(\frac{hd}{d}\right)^2$$

or, $\alpha = k_1h^2a$, $\beta = k_2h^2b$, $\gamma = k_3h^2c$, $\delta = k_4h^2d$.

If we suppose the four volumes to be mixed, new equations will make their appearance which have the form $\frac{\alpha}{a+b+c+d} = k_1\frac{h(a+b)(a+c)}{(a+b+c+d)^2}$, &c., and which can be brought to the form

$$\alpha = \frac{k_1h^2(a^2+ab+ac+bc)}{a+b+c+d},$$

$$\beta = \frac{k_2h^2(b^2+ab+bd+ad)}{a+b+c+d}, \text{ \&c.}$$

The quantities α, β, γ, and δ are to remain unchanged, according to the assumption. Now, by dividing the corresponding equations by each other, the same equation follows from each pair

$$ad = bc,$$

i.e. the volumes a, b, c, d of the four solutions must be such that the products of the volumes of such pairs of solutions as contain no common ion must be equal to each other.

Now, the volumes a, b, c, and d are proportional to the active or dissociated portions of the four substances present. Calling the total quantities of the latter, p, p_1, q, and q_1, the values a, b, c, and d are proportional to m_1p, m_2p_1, m_3q, and m_4q_1, and hence we get from $ad = bc$ the equilibrium formula

$$m_1p \,.\, m_3q = m_2p_1 \,.\, m_4q_1$$

This equation represents not only Guldberg and Waage's formula for chemical equilibrium, but it also contains the extension, made by Ostwald, that every co-efficient of the Guldberg and Waage equation, $k_1pq = k_2p_1q_1$, is made up of two factors each of which depends only on the nature of the ions.

But the equation goes still further than this extension. In the theory of affinity the co-efficients m_1, m_2, &c. have been considered as constant to a first approximation. But from what has been said it follows that they are not constant; they depend on the state of dissociation of the four substances, and are rather complicated functions of the dissociation-constants, of the quantities, and of the total volume. The various deviations from the simple laws which were brought to light by experiment find here their appropriate explanation. Thus it follows that in the case of slightly dissociated acids the degree of dissociation must be considerably lowered by the presence of the normal salts of these acids, which salts are themselves considerably dissociated. The corresponding fact, that such mixtures act much less strongly than the quantity of free acid present in them would do, was known long before theory explained it.

Arrhenius has subjected his investigations on the saponification of ethyl acetate by means of ammonia in the presence of different salts (*Z. P. C.* 1, 110) to an examination from the standpoint of these newly-established ideas (*ib.* 2, 289), and has everywhere found them to be in complete agreement with experiment. He has also re-examined a great number of older investigations on conditions of chemical equilibrium in the light of his theory (*ib.* 5, 1), and here also the discrepancies found when considered from the point of view of the older theory have for the most part disappeared (*v.* also *Z. P. C.* 9, 487).

Electromotive forces. Contact theory or chemical theory?[1]

The laws of electromotive force, or of differences in potential produced on the contact of different substances, are not nearly so well known as those of electrical conductivity. It is true the knowledge of the phenomenon itself is as old as that of galvanic electricity, since Volta had already carried out the first approximate measurement of it, but up to the present day no agreement has been arrived at between the different investigators concerning even the chief phenomena.

Volta screwed a disc of zinc coated with isolating varnish on to his straw-electrometer; on the top of this he placed a similar disc of copper, connected the two discs metallically, and after the connection had been broken he took off the copper disc by means of an insulating handle. The electrometer then proved to be charged; examination showed that the straws were charged with positive electricity.

This phenomenon indicates that the substances used—that is zinc, copper, and the isolating coating—charge each other electrically on contact. Volta assumed that, of the three contacts, only the one between copper and zinc was electromotively active; the contact between the metals and the isolating layer of resin was regarded by him as indifferent. Though neither then, nor up to the present day, has a proof of this assumption been brought forward, it has yet met with fairly universal acceptance, and it often passes as a fact not to be doubted.

On the further assumption, which certainly is incorrect, that liquids also—such as water or salt solutions—show no differences of potential with the metals, Volta constructed his electric pile by superposing alternately two metals and a moist card disc. By this he expected an intensification of the electrical effects, since the electricity of the metal lying underneath was to communicate itself through the moist discs to the one lying above, without any change, and so the effects of the individual pairs of metals were to be added together. Volta did, in fact, obtain the expected intensification—a proof that great discoveries may be made on the basis of quite false hypotheses.

Fabbroni first refused to accept the assumption that the tension of the voltaic pile has its seat only at the point of contact of the metals, and numerous other investigators have taken the same line. Faraday especially, whose work in electrochemistry ranks with the most important done in this subject, was an opponent of Volta's views. He attributed the production of the electric current solely to the chemical processes present, and transferred the cause of the production of electricity to the places at which these processes occur—*i.e.* the point of contact between the metals and the electrolytes.

The contention thus aroused between the contact theory and the chemical theory of the galvanic cell has lasted to the present day, and even now it is not completely decided. But most of the discussions raised have certainly originated in the insufficient lucidity with which the questions have been stated.

In so far as a galvanic current can be produced only by using electrical energy, it can be maintained, to begin with, that in order to cause a galvanic *current* there must be present a corresponding source of energy. If other kinds of energy are excluded, as is the case in an ordinary galvanic cell, it can further be said that chemical energy changes into electrical energy, and that, therefore, a theory of the electric *currents* produced by the voltaic cell must in any case be a chemical one.

But to an electric current there appertain two factors: a quantity of electricity, and a difference of potential. The first is given by the law of Faraday. Since in electrolytes the motion of electricity takes place only simultaneously with the motion of the ions, equivalent quantities of the different ions carrying equal quantities of electricity, a current in a galvanic cell can again not be produced without a corresponding chemical process. From this point of view, also, the theory must be a chemical one. As regards the other factor of the current energy—*i.e.* the difference of potential—an unequivocal decision, as in the preceding cases, can certainly not be pronounced easily. The experiments on this subject, taken alone, have proved that all substances, when separated from each other after close contact, show themselves to be electrically charged. The smallest differences suffice for this. It has been long known, for instance, that black and white silk stockings which have been pulled over each other are electrically charged after separation. Even in such homogeneous materials as crystals of mica or calcite, the two parts obtained by cleavage of the layers are found to be in different electrical conditions at the original point of contact.

It is imperative, therefore, to accede to the proposition of the 'contact theory,' in so far as to admit that a process occurs at the surface of contact when two surfaces touch, in consequence of which the surfaces are at different potentials after separation. We do not know what the nature of this process is. Helmholtz supposes the different substances to possess a different attraction for electricity, in consequence of which there is brought about a separation of the electricity at the planes of contact; then when the bodies are separated they appear electrically charged. A difficulty with respect to this theory is found in the electrical phenomena attending the cleavage of crystals, where a difference in attraction seems excluded.

---

[1] A complete discussion of this question by O. Lodge is to be found in *P. M.* [5] 19.

In order that the equilibrium of electricity may be changed when two bodies charge themselves oppositely on contact, the expenditure of a certain quantity of energy is required. The source of this energy has to be sought in the change which the surfaces of the bodies undergo owing to their mutual contact.

In order that this difference of potential may cause an electric current, two things are needed. Firstly, the bodies touching must be conductors, as otherwise the electricity cannot move; and secondly, a cause must be present which will maintain unchanged the condition of the surfaces in contact, in consequence of which condition the arrangement of the electricity is changed; otherwise a charging motion of the electricity could take place once only, but not a continuous current. The current can be produced by mechanical action, and then the phenomena of frictional electricity appear, or the renewal of the surfaces occurs by chemical action, and we deal with galvanic cells.

When considered from this point of view also, the chemical processes appear as the causes of galvanic currents, and a final theory of these currents will doubtless be much more a 'chemical' than a 'contact' theory.

Galvanic cells. The simplest conditions for examining the relations between chemical and electrical energy are found in the so-called *constant galvanic cells*, of which the Daniell cell is a type. This cell consists of a copper plate in a solution of copper sulphate, and a zinc plate in a solution of zinc sulphate; both solutions are in contact with each other. Such a galvanic cell has an electromotive force of about 1·09 volts, which does not change appreciably when the metals are connected by a conductor, and the galvanic current is thus allowed to pass for a longer or a shorter time.

The chemical process in such an element is also of the simplest kind: zinc dissolves to zinc sulphate, while copper is separated from the copper sulphate. Hence the same process takes place as when a piece of zinc is brought into a copper sulphate solution.

The chemical energy which is available in this process can easily be measured by experiment; it proves to be 50,100 cal. for the reaction

$$Zn + CuSO_4Aq = Cu + ZnSO_4Aq.$$

Now, since (p. 180) the unit of electrical energy, volt × coulomb, is equal to 0·2356 cal., this quantity of heat corresponds to 212,600 electrical units.

Now, of the two factors making up the electrical energy of the voltaic cell, one is given by Faraday's law. One gram-equivalent of a metal carries (p. 180) 96,540 coulombs. Since copper and zinc are divalent, the above equation refers to 2 gram-equivalents; when, therefore, 65 g. of zinc dissolve in the Daniell cell, 193,080 coul. are transferred. Dividing this value into the number 212,600 (volt × coulomb), we get 1·10 volts for the electromotive force of the Daniell element, a number which agrees well with the observed value.

This calculation was first carried out by W. Thomson with the help of numbers due to Joule. From the agreement between observation and calculation, the inference was drawn that the assumption made in this case—namely, that the chemical energy transforms itself completely into electrical energy—was universally correct. From this was deduced the possibility of calculating, on the basis of thermochemical data, the electromotive force of all constant elements, and further, the electromotive force of all elements in which the chemical process is known. It was only necessary to multiply the heat of the reaction referred to one *equivalent* (not molecular weight) by $\frac{0·2356}{96540} = 0·00000244$. It would also follow that the electromotive force of all cells would be proportional to the heat of the chemical reaction.

This theory could not, however, be maintained. On the one hand, theoretical doubts were raised, and that specially by Braun (*W.* 5, 188), against the premisses that the chemical energy of the galvanic cell was always completely transformed into electrical energy; and, on the other hand, experience proved that as a rule the assumed proportionality between heat of reaction and electromotive force did not exist. Raoult (*A. Ch.* [4] 4, 392) discovered a number of cells, some of which produced less, and some produced more, energy than corresponded to the heat of reaction of their chemical changes; and at a later time it was proved—chiefly by F. Braun and Alder Wright (*P. M.* [5] 19, 1), by means of direct measurement—that only in rare cases do the chemical and electrical energy exactly correspond to each other.

The simple theory must, therefore, be abandoned, and without assuming that the chemical energy is wholly transformed into electrical energy, we must seek to discover a relation between the two. Such a formula has been found by W. Gibbs and H. von Helmholtz (*B. B.* 1882). The following statement is a simple way of deducing this equation. Let there be given a galvanic cell whose heat of reaction calculated for one equivalent is W. Let its electromotive force at the absolute temperature τ be ϵ. On raising the temperature by $d\tau$ the electromotive force is changed by $d\epsilon$.

Now let us carry out the following cycle. The cell is heated from τ to $\tau + d\tau$. Then let the quantity of electricity q, by means of which one equivalent of the reacting substance undergoes chemical decomposition, pass through the cell, the electromotive force remaining $\epsilon + d\epsilon$, and the temperature being kept constant. Now let the temperature be brought to τ and, the electromotive force being ϵ, and the temperature being constant, let the same quantity of electricity q be passed through the element in the opposite direction. Thereby the element returns exactly to its initial condition.

According to the mechanical theory of heat, the portion of heat transformable into work, in a reversible cycle taking place in the temperature-interval $d\tau$, is $\frac{d\tau}{\tau}$ of the total quantity of heat produced. Now, the work is given by $qd\epsilon$, and the total heat which has been communicated to and taken from the cell is $\epsilon q - W$. If an electric current alone were produced, the quantity of heat would be ϵq. But since a chemical process also takes place, which yields a portion of the heat—namely, the heat of reaction, W—it is only necessary to communicate the difference $\epsilon q - W$.

We have then the equation—

$$\frac{d\tau}{\tau} = \frac{qd\epsilon}{\epsilon q - W}$$

or

$$\epsilon = \frac{W}{q} + \frac{1}{\tau} \cdot \frac{d\epsilon}{d\tau}$$

The former equation was $\epsilon = \frac{W}{q}$; we see, therefore, that a correcting term must be added, and that this term is dependent on $\frac{d\epsilon}{d\tau}$, that is, on the change of electromotive force with change of temperature. In the case that $\frac{d\epsilon}{d\tau} = 0$, the new equation is the same as the old one; in the Daniell cell the temperature co-efficient is, in fact, nearly equal to zero, and thus it is explained that in this case the chemical energy is equal to the electrical energy.

The equation has been examined in many ways. At first it gave only partially correct results, and in some cases observation and calculation differed from each other. The differences occurred, however, only in cells which contained mercury compounds, and the cause was the use of a wrong number for the heats of formation of these compounds. When this error was corrected by Nernst (*Z. P. C.* 2, 23) the discrepancies disappeared; and a very careful investigation by H. Jahn (*W.* 34, 755), in which the thermal and electrical quantities were measured simultaneously, has fully confirmed the correctness of the Gibbs-Helmholtz formula.

The formula has been deduced primarily for constant galvanic cells, and when deducing it the conditions assumed have been expressed; the chemical process resulting from the passage of the quantity of electricity q (which, however, can be as small as we will) must be reversible, by allowing the same quantity of electricity q to pass through the element in the opposite direction. In order that a galvanic cell should fulfil this condition, it is generally requisite that each metal should be surrounded by its corresponding salt. Therefore, when the salt is soluble, the metal must stand in a solution of the salt. In the case of insoluble salts it generally suffices to cover the metallic surface with the solid salt; in this case, either the salt of another metal with the same acid (which salt is not precipitated by the first metal), or the free acid itself, serves as the electrolyte.

The action in a Daniell cell is as follows. Individual atoms of the metal pass from the zinc as positively charged ions into the solution of the sulphate. Since no free electricity can exist within the solution, the copper ions of the copper sulphate must go to the copper plate, where they give up their positive electricity, passing into ordinary metallic copper. Owing to this action, a motion of the positive electricity from the zinc to the copper takes place in the solution; on connecting both metals by a wire the current passes continually through it, corresponding quantities of zinc and copper being dissolved, and precipitated, respectively. If the cell is not closed, the zinc becomes charged negatively, owing to the exit of positive ions, and the copper positively, owing to their entrance; and this goes on until the attraction of the zinc for the positive ions, and their repulsion by the copper, is so great that neither can zinc pass into solution nor can copper separate out. The capacity of the ions being enormous, this is brought about by even extremely small numbers of them.

Nernst, who has studied these changes in detail (*Z. P. C.* 4, 129), assigns to the metals which are in contact with electrolytes definite *solution pressures*, just as volatile liquids or solids have definite vapour pressures. This pressure is the cause of zinc tending to pass into solution. The solution pressure of copper is very much smaller than that of zinc. Hence when the Daniell cell is newly set up, both metals will at first send positive ions into the solution. But, since no free electricity can exist in the interior of the solution, that metal which has the greater pressure will maintain the preponderance; its ions will pass into solution, and, in order that no free electricity may accumulate in the liquid, an equal number of copper ions must leave the solution, and be precipitated in the metallic state.

Similar arguments hold for all reversible elements. By their help, and with the help of the theories of electrolytic solutions expounded above, a great number of special cases referring to galvanic cells can be deduced theoretically. The results thus obtained have, on the whole, been confirmed by experiment; but details cannot be entered into here.

Besides the constant galvanic cells of the type just described, which are *reversible*, there still exists a great number of cells which, though practically constant, are not reversible. The constancy of these cells rests on the fact that the nature of the surfaces in contact is not altered by the chemical processes. When metal dissolves at the surface of the zinc, and when metal deposits at the surface of the copper, the nature of the bounding surfaces is not thereby influenced; this cell is also reversible, because on sending a current through in the opposite direction zinc is precipitated and copper dissolved, but the surface again undergoes no alteration.

Cells of the type of that of Grove, which consists of zinc in sulphuric acid and platinum in nitric acid, are also constant. On working this cell, zinc dissolves, expelling the hydrogen ions from the sulphuric acid; these hydrogen ions go to the nitric acid, whose own hydrogen ions go to the platinum; at the moment when they give up their positive electricity there, and pass into ordinary hydrogen (which, however, is in the nascent state), they are oxidised by the nitric acid to water, and the platinum surface remains unaltered. But such elements are not *reversible*. When an opposite current is passed through the cell, since the platinum ions cannot pass into solution, the ions NO_3 of the nitric acid separate out at the platinum, while hydrogen appears at the zinc; both these actions change the condition of the bounding surfaces, and thereby simultaneously change the electromotive force also.

Finally, there still remains the large group of the non-constant cells. These are distinguished by the fact that even when the current passes through them in the direct way, the ions separated out produce an alteration in the bounding surfaces, or in one of them at least. To these belongs Volta's cell, which consists of zinc and copper in salt water, and all the other similar combinations. A type still in use is Smee's cell, which consists of zinc and platinum in dilute sulphuric acid. On closing the circuit, zinc ions enter into the solution, expelling the hydrogen, which gives up its electricity at the platinum, whereby it first combines with or dissolves in the metal, and when that is saturated escapes in the gaseous form. In consequence of this, the surface of contact between the acid and the platinum is altered, and the electromotive force also changes, until saturation with hydrogen has taken place; after this point has been reached the electromotive force of Smee's cell remains practically constant. If the cell is left with the circuit open, the hydrogen gradually disappears, partly through diffusion into the air, partly through combination with the free oxygen of the air, induced by the catalytic action of the platinum. Thus, the cell again gradually resumes its original electromotive force. Such cells are, therefore, quite workable in cases where only small quantities of electricity are required at long intervals.

The seat of the electromotive forces. Volta found that no galvanic pile, giving a current, could be produced from metals only. When considered from the point of view of the principles of energy, such behaviour follows necessarily, because, no continuous source of energy being present in a circuit of metals alone, no current can be produced.

The cause of this may be of a two-fold nature. Either there exist no differences of potential between metals, or these follow a definite law, which involves that in a closed circuit these differences just neutralise each other. With Volta, we will assume the latter alternative, of which the former is only a special case. If, then, we have several metals A, B, C. . . and if we call the differences in potential between A and B, A and C, B and C, &c., in succession $(a-b)$, $(a-c)$, $(b-c)$ . . . the law is that we must always have $(a-b)+(b-c)+(c-d)+\ldots+(y-z)=(a-z)$. The difference of potential of a series of metals depends only on the nature of the first and the last metal, and not on the nature of the intervening metals.

This result necessarily follows if the values a, b, c . . . in the quantities $(a-b)$ &c. are considered as the potentials of the individual metals referred to a zero value which must be fixed arbitrarily. For the zero value of potential we generally use the potential of the earth, or, more correctly speaking, that of a large metallic mass which is in connection with the earth, as are, for instance, iron water-pipes. It can, therefore, be assumed that every metal connected with the 'earth' assumes a definite value of potential which depends only on the nature of the metal. These values of potential are the same for every metal, whether the different metals are in contact with each other or not.

In order to measure these differences of potential, the experiment of Volta mentioned before (p. 212) has been improved upon, in that instead of a dividing layer of resin one of air is used; and, dating from the time that R. Kohlrausch (*P.* 75, 88) thus carried out the first experiments, a great deal of similar work has been done.[1] But in this case also we are dealing, not with one, but with three separating surfaces—namely, copper-zinc, zinc-air, air-copper, and only when we make the assumption that the differences of potential at the last two surfaces are zero, are we enabled to judge from the measurements of the total difference of potential as to the difference between the metals.

The legitimacy of this assumption has formed the subject of much discussion. Considering the universality of differences in potential between heterogeneous substances, the absence of a difference between metal and air would be very strange, and we are quite entitled to demand a proof of it from the champions of this view. But, on the contrary, it seems as if the following fact proved the existence of such differences of potential. All the investigators who have undertaken such measurements complain of the extraordinary inconstancy in the differences of potential observed. On placing two freshly-cleaned plates opposite to each other and measuring their difference, one is sure to find different values after a little time. If the surfaces are again cleaned, the original values approximately recur. Therefore, it is not the point of contact of the two metals (besides, this can be made unalterable by soldering), but their surfaces with respect to air, which are the seat of the changes. Let us now assume that at a definite moment the difference of potential of both plates towards air is equal to zero; since another value is observed after some time, the difference of potential of the metals towards air cannot now be zero, *i.e.* between metals and air there exist differences of potential. How great these are cannot as yet be determined. There is nothing against the assumption that these make up the greatest part of the apparent differences of potential between the metals (measured in air). It is true an attempt has been made to eliminate the influence of the air by making the experiment *in vacuo*. But since we have learned by observation of the electrical phenomena in vacuum tubes, how difficult—how impossible, even—it is to withdraw from a substance the last remnants of air condensed on it and in it, these experiments cannot be looked upon as affording any conclusive proof.

Other methods for solving the difficulties must be sought. Unfortunately, there does not exist a single process quite free from objection. The following consideration still appears to be the best:—

When a given quantity of electricity q is brought from a potential A to a higher potential $A+a$, a quantity of work aq is required. Therefore, when we lead a current through two metals which touch in one place, and which there exhibit a difference of potential *a*, an absorption or a production of energy will occur at the place of contact, according to the direction of the current; and, if there is no other source of energy, this energy-change will be produced from, or will be added to, the heat which is present, as the case may be. In the case of metals such a phenomenon is actually known; it is the effect discovered by Peltier (*A. Ch.* 56, 371 [1834]). If the strength of the current, and the total heat produced, are measured, the corresponding difference of potential can be calculated. Such experiments have been made by Le Roux, and again quite recently, with great accuracy, by H. Jahn (*W.* 34, 755), and the results have shown the values to be very small; they are mostly only a few thousandths of a volt.

---

[1] Compare O. Lodge, *l.c.*

It is true we must not pass over in silence the following objection made against the validity of this argument. Since we know nothing definite concerning the nature of the electric current, the possibility is not excluded that it may be connected with movements of energy of other kinds. It has been especially assumed as probable by several authors that, simultaneously with the electric current, a heat-current flows through the conductor. If so, the quantity of heat flowing with the unit quantity of electricity might be different in different conductors; and at the point of contact of the metals, in addition to the thermal exchange resulting from the difference of potential, there might occur a further exchange of heat resulting from the difference in the 'thermal capacity of electricity.' Since these two quantities need not have a necessary connection, it would not be permissible to draw any conclusion from the Peltier effect—that is, from the sum of two independent effects—as to the magnitude of the difference of potential.

Without attempting to decide this difficult question here, I should like to draw attention to a circumstance which makes it probable that the second effect, if present at all (which so far has not been proved), must probably be of the same order of magnitude as the difference of potential corresponding to the Peltier effect. According to the second law of the mechanical theory of heat, the carrying of a definite quantity of heat Q from a lower to a higher temperature involves work which is given by $Q\frac{T_1 - T_2}{T_1}$. If, therefore, we pass an electric current through a wire whose temperature varies, it follows that, if heat is carried with the current, in places of rising temperature a corresponding quantity of work must be expended, *i.e.* an opposing electromotive force must there assert itself. Indications of such a force appear to manifest themselves in the so-called Thomson effect (supposing that this effect does not find its explanation in differently heated portions of one metal having differences of potential to each other), but in any case the quantities of work, or the differences of potential, indicated by this phenomenon are extremely small (of the same or of a smaller order of magnitude as those corresponding to the Peltier effects), so that the assumption of an appreciable carrying of heat by means of electricity (for which, at any rate, we lack the power of forming a conception) seems excluded.

From this it is evident that though nothing quite certain is known concerning the differences of potential between different metals, yet preponderating reasons favour the assumption that such a thing does exist, but that its magnitude does not exceed a few thousandths of a volt, and particularly that it does not attain the order of magnitude of 1 volt. But, varying slightly with the nature of the metals, such a value has been observed by means of the air-condenser method.

As regards differences of potential between various electrolytes, such differences certainly do exist. This can be inferred from the fact that there exist 'liquid chains,' *i.e.* combinations of different liquids, which produce an electric current. If, for instance, we put into a series of beakers water, concentrated hydrochloric acid, concentrated soda solution, and water, and if we connect these by small syphons or by moist threads, then the two quantities of water at the ends exhibit a difference of potential which may attain to 0·5 volt.

In such liquid chains we have always to deal with three distinct differences of potential at least; designating the three liquids named above by A, B, and C, there exist in the chain the differences of potential $(a-b)$, $(b-c)$, and $(c-a)$, whose sum is observed. There is no combination of the liquids by which we could succeed in obtaining as many independent observations as there are differences of potential, so that it is impossible to determine by measurements on liquid chains only the individual differences of potential.

This determination has, however, been achieved in another way. Since in electrolytes the electricity moves only with the ions, differences in potential between two liquids in contact can only be produced if the different positive and negative ions distribute themselves unequally. A cause for such an inequality lies in the different velocities of migration of the ions (p. 92), and, in an extensive investigation, W. Nernst has shown (*Z. P. C.* 4, 129) how thereby the actually observed differences of potential can be theoretically calculated in a great number of cases. The fundamental idea of these calculations is the following. When any solution is brought into contact with pure water, forces make themselves apparent at the surface of separation, which forces can be calculated by van't Hoff's theory (pp. 184–5); for 'normal' solutions (which contain one gram-molecular weight per litre) they are equal to the pressure of about 22 atmospheres, and they are proportional to the quantity of substance in the solution. Owing to the osmotic pressure, the molecules of the substance are forced into the water. The velocity of their motion is determined by the resistance which they encounter, and this depends on their form as well as on the nature of the solvent.

This statement contains a physical theory of hydro-diffusion (Nernst, *Z. P. C.* 2, 613), and from it the law of Fick follows directly, that the velocity of diffusion at any point is proportional to the change in concentration at that point. From this we see at once how a separation must occur in the diffusion of dissolved substances, because those molecules which are endowed with greater mobility or suffer less friction outstrip the slower ones. The same laws hold for each kind of molecules, only the constants are different.

These arguments can only be applied immediately to electrolytes in solution if both ions have equal rates of motion. This condition is very nearly fulfilled in the case of potassium chloride, and this substance conforms, therefore, to the simple law of diffusion.

It is now possible, in the case of electrolytes, to determine the resistances which the ions encounter, as well as to measure the impelling forces. If the ions are moved past each other by *electrical* forces of separation, they encounter exactly the same resistance, and since in the electrical conductivity we have a measure of the velocity of the corresponding motion of the ions, it is possible, as first shown by F. Kohlrausch (*W.* 6, 160), to calculate the magnitude of the resistances from a knowledge of the impelling force and of the velocity attained. On introducing this resistance (which, owing to the smallness of the molecules, is enormously great) into the equation for the velocity of diffusion, indicated above, Nernst has found (*l.c.*) that the velocities of diffusion agree very well with the results of experiment.

In the case of electrolytes whose ions do not migrate with equal velocities the phenomena become much more complicated. If, for instance, we imagine hydrochloric acid, in which the hydrogen ion travels about six times more quickly than the chlorine ion, to be brought into contact with water, the quicker hydrogen atoms will, to start with, pass into water, and the chlorine atoms will remain behind. But since the hydrogen atoms are charged with positive electricity, the water will become positively electrified, while the acid, owing to the preponderance of chlorine atoms, becomes charged negatively. But the further exit of hydrogen atoms is thus rendered more difficult, owing to the electro-static effect, while from a similar cause the chlorine atoms are subject in addition to the osmotic pressure, and also to an electric impelling force, and are thus driven into the water. The consequence is that both ions influence each other's velocity until they again migrate at equal rates.

At the same time, we see that every electrolytic solution whose ions travel with unequal velocities on contact with water—or, speaking more generally, on contact with a solution of different concentration—at once acts as the cause of difference of potential, and also that the more dilute solution will always assume the sign of the ion which has the greater migration velocity. The exact expression which has been deduced by Nernst (*l.c.* p. 138) is

$$\epsilon_1 - \epsilon_2 = 0{\cdot}0000860 \quad \tau \quad \frac{u-v}{u+v} \, log. \frac{p_1}{p_2}$$

Where $\epsilon_1 - \epsilon_2$ is the difference of potential (in volts) of two solutions in which the osmotic pressures of the (positive as well as negative) ions are p_1 and p_2; u is the velocity of the positive, v that of the negative, ion; τ is the absolute temperature, while *log.* stands for the natural logarithm.

We see that for $u = v$ the electromotive force becomes zero, and it becomes the greater the greater the difference between the migration-velocities of the two ions. Further, we see that as regards the electromotive force, only the ratio $\frac{p_1}{p_2}$ of the two pressures, and not their absolute values, enters into consideration. By increasing the concentration n times in both solutions, the difference of potential does not change. If one of the solutions is pure water, we get $p_2 = 0$, and the electromotive force becomes infinitely great. Since 'pure water' in this sense does not exist, such values cannot come under our observation. But yet we see that liquid chains with 'water' can give very different values according to the degree of purity of this liquid.

The preceding formula is the fundamental expression for all kinds of liquid chains, since in the combination of any solutions the corresponding differences of potential are superposed. It would take us too far afield to enter into the different cases; in the memoir of Nernst, a number of cases are discussed theoretically as well as experimentally. But on the whole it may be concluded that the differences in potential apparent on contact of approximately equally concentrated solutions of the most varied kind, vary within fairly small limits, which probably do not surpass 0·01 volt.

Now, since we cannot suppose that differences of potential of the order of magnitude of those observed in galvanic cells exist either between metals alone, or electrolytes alone, we are obliged to regard the surfaces of contact between the metals and the electrolytes as the real seat of the electromotive forces. This result quite corresponds with what was to be expected from the relations between the chemical and electrical energies. This is so because these surfaces of contact are the only seat of the processes by which energy becomes available in the chains, *i.e.* they are the result of the chemical changes. Since, on the one hand, the cause of the galvanic current of the chains has to be sought in the transformation of chemical into electrical energy, and since, on the other hand, a galvanic current can be produced only when a difference of potential exists, it does not seem very logical to wish to separate in space, and in their nature, the more approximate and the less approximate causes of the same phenomenon, as is done in the assumption that the difference of potential is to be sought at the surface of contact of the metals.

The question now arises again, whether some means does not exist for directly measuring the differences of potential between metals and electrolytes. The answer is that up to the present only one such means is known. A second independent way for arriving at these numbers does not as yet exist, and hence it has hitherto been impossible to put to the proof the results obtained by that method.

The method in question is based on the phenomena exhibited by mercury surfaces when in contact with electrolytes. Lippmann (*P.* 149, 561; *A. Ch.* [5] 5,494) has shown that there is a close connection between the condition of the surface of mercury touching an electrolyte and the electrical state of the system. If, for instance, mercury is covered with dilute sulphuric acid, and the surface of contact between the two is then increased, a galvanic current is produced, because the mercury becomes less positive on expansion. This can be observed most easily by allowing mercury to drop out of a funnel with a small orifice immersed in dilute sulphuric acid. On connecting the mercury in the funnel and that collected below the sulphuric acid by means of a galvanometer, a current passes from the lower mercury to the higher; in the sulphuric acid the reverse occurs.

This phenomenon is reciprocal. On leading a current through the surface of contact between mercury and sulphuric acid the surface tends to diminish or to increase, according to the direction of the current—*i.e.* the capillary tension at this point changes. As is always the case, both phenomena are in such a relation that they oppose each other—*i.e.* when the surface is made larger the current has the direction such that if it alone were active it would tend to make the surface smaller, and *vice versâ*.

Helmholtz (*W.* 16, 35 [1882]) has given a theory of these phenomena which is based on the following considerations. When a metal and an electrolyte are in contact, they generally possess a varying difference of potential. Owing to this circumstance, the opposite electricities must accumulate on both sides of the bounding surfaces, since they are prevented from combining by the cause which produces the difference of potential (and which, without making a definite assumption, can be designated as a different attraction of the substances for the electricity). The result is the formation of an 'electric double layer,' which will exhibit a similar arrangement to the charge of a Franklin plate.

But such a double layer will have the property of tending to increase its surface as much as possible, since the similarly electrified particles present at each side repulse each other, and therefore tend to stretch the surface. Hence the development of such a double layer will act in opposition to the surface tension, which seeks to decrease the surface, and the actually observed surface tension is the difference between the real tension and the electric force.

When a surface so constituted is made larger, the electric layers are thereby extended, and their difference of potential decreases. But since, as is known from experience, a constant difference of potential is always formed at the boundary, which difference of potential does not depend on the size of the surface of contact, electricity will flow from the mercury as well as from the electrolyte to replace the loss, and in this way the current is produced.

If, on the other hand, the difference of potential of the electric double layer is changed, the surface tension must change also. It must get smaller when the difference of potential is made larger, and larger when it is made smaller.

By leading electric currents of varying electromotive force through a system consisting of two masses of mercury in sulphuric acid—one of which had a very small, the other a very large, surface of contact with the acid—Lippmann was able to follow the change of surface tension at the small bounding surface which accompanied the change in the difference of potential at that surface. Because, since the change in the difference of potential between a metal and an electrolyte is proportional to the *density* of the current (current strength divided by the cross-section), the resulting difference of potential practically restricted itself to the small bounding surface, which was surpassed in extension some thousand times by the large one. It was found that when the mercury of the small surface was connected with the positive pole of the external cell, the surface tension decreased. On the other hand, when negative electromotive forces acted, the surface tension increased until the external force was 0·9 to 1·0 volt; beyond that it again decreased.

In accordance with Helmholtz's theory, we must infer from this that the difference of potential between mercury and sulphuric acid is of such a kind that the former becomes charged positively—*i.e.* that the positive electricity of the double layer is on the side of the mercury, and the negative electricity is on the side of the electrolyte. If the difference of potential is increased by addition of positive electricity to the mercury, the electric repulsion increases, and therefore the surface tension decreases. If, however, negative electricity is added, the charge of the double layer decreases and the surface tension increases. On making the successive additions of negative electricity larger and larger, the difference of potential of the double layer eventually becomes zero; the surface tension has reached its greatest value, and, beyond this, a new double layer of opposite sign is produced. When this state is reached, the surface tension must again decrease.

According to the experiments of Lippmann, the maximum of surface tension is reached when the external electromotive force is 0·9 to 1·0 volt. Then no more double layer is present at the small surface of the mercury, and the metal and electrolyte have the same potential. Since this condition is separated from the ordinary one by about 0·9 volt, *it follows that the usual difference of potential between dilute sulphuric acid and mercury is 0·9 volt.*

This result is confirmed by the following experiment of Pellat (*C. R.* 104, 1099). When the surface of contact between mercury and sulphuric acid is increased, a motion of electricity is produced, owing, as has been mentioned above, to the stretching of the double layer. But this must disappear when, by the use of a difference of potential of about 1·0 volt, the double layer has been made to disappear; and, in fact, under these conditions, Pellat, on changing the surface, could observe no current.

Another confirmation can be obtained in the following manner. When mercury is dropped very quickly out of a fine point into an electrolyte, it must, after a short time, as Helmholtz has shown, assume the potential of the latter (*W.* 16, 35), because if, for instance, the mercury were at the beginning positive, every falling drop would form a double layer at its surface, which would take positive electricity out of the mercury, and which would make its positive potential smaller and smaller till it became equal to that of the liquid.

But it is to be remembered that the mercury in contact with sulphuric acid spontaneously becomes positively charged; everything will depend, therefore, on allowing the formation of drops to take place as quickly as possible, in order that the discharge may preponderate over the charge. Experiments by W. Ostwald (*Z. P. C.* 1, 583 [1887]) have shown that the discharge can be achieved to a great extent, but not completely; there still remain over, even with the best dropping electrodes which have yet been made, differences of some hundredths of a volt. But within these limits the experiment confirms the conclusion which Helmholtz had drawn—the difference of potential between the dropping electrode and the mercury at rest in sulphuric acid amounts in 'normal' sulphuric acid solution to 0·81 volt, while the maximum of surface tension (that is, the true difference of potential) lies at 0·86 volt.

Finally, another inference, which must be drawn from the theory of Helmholtz, has been confirmed by the same author. If the maximum of the surface tension of mercury, as obtainable by means of suitable electromotive forces, actually is the real surface tension of mercury in contact with aqueous liquids, free from auxiliary effects, then it must have the same value whatever be the nature of the electrolyte, while experience shows that the natural surface tension changes considerably with the nature of the electrolyte. This also was confirmed; while the natural surface tension in different solutions varied between 485 and 561, the maximum values were 610 to 644, and were, therefore, practically constant.

All these facts speak for the correctness of Helmholtz's theory of the electric double layers, and leave us, therefore, with the final conclusion that the electromotive force required for producing the maximum of surface tension of mercury in contact with an electrolyte is equal to the ordinary difference of potential at this bounding surface (but with inverted sign). But it must be again emphasised that this is the only group of phenomena from which the values considered can be deduced. An examination of the results by means of another entirely independent method has not yet been feasible.

If, now, the difference of potential between mercury and sulphuric acid is known, the difference of potential between all other metals and sulphuric acid can be measured by experiments which are easily carried out. For this purpose the electromotive force of the combination *mercury, sulphuric acid, and metal* alone need be measured; this is the sum of the differences of potential of mercury-sulphuric acid and sulphuric acid-metal, and since the first of these is known the other follows by difference. But here it is supposed that no appreciable difference of potential exists between the metals. Again, if the difference of potential between mercury and any other electrolyte is determined, either by the maximum surface tension or by means of the mercury-dropping electrode, the difference of potential of these electrolytes against any other metals can also be determined. In this manner, therefore, the whole subject of the differences of potential between metals and electrolytes has been made amenable to measurement.

But few trustworthy measurements of this kind have as yet been made; in the following table some numbers are given:—

	HCl	HBr	HI	H_2SO_4
Zn . .	−0·54	−0·46	−0·30	−0·62
Cd . .	−0·24	−0·18	−0·08	−0·22
Sn . .	+0·02	+0·12	+0·28	−0·02
Pb . .	+0·03	+0·10	+0·26	−0·04
Cu . .	+0·35	+0·35	+0·36	+0·46
Bi . .	+0·41	+0·47	+0·60	+0·46
Sb . .	+0·51	+0·60	+0·54	+0·48
Ag . .	+0·57	+0·51	+0·45	+0·73
Hg . .	+0·57	+0·50	+0·44	+0·86

The values refer to 'normal' solutions of the electrolytes mentioned, and indicate the potential of the metal when that of the electrolyte is put equal to zero.

We see that those metals which dissolve in the acids become negative; the others become positive. The values are also in very nearly the same order as the corresponding heats of reaction, but, as a calculation shows, they are not proportional. The nature of the electrolyte has generally a smaller influence than that of the metal, but there are cases where the reverse is true.

It should be mentioned that nearly the same numbers are obtained when salts of the acids, with metals which are not precipitated by the metal under examination, are used instead of the acids themselves. The difference of potential between the metal and the electrolyte depends, therefore, chiefly on the negative ion of the latter. From the numbers in our possession it is seen, for instance, that in the Daniell cell, whose difference of potential is 1·08 to 1·10 volt, the greater part of this (0·62 volt) is present at the bounding surface between zinc and zinc sulphate, and the smaller part at the surface (0·46 volt) between copper and copper sulphate.

No further conclusions of more general interest have as yet been drawn from these numbers.

Galvanic polarisation. When two metal plates are introduced into an electrolytic liquid and a galvanic current is made to pass through the electrolyte by means of the plates, these plates generally become the seat of a new electromotive force which acts in opposition to the current already active. This phenomenon is called *galvanic polarisation*, and it may be perceived by connecting the plates with a galvanometer immediately after breaking the primary current.

The cause of this phenomenon is to be found in the change which is produced by the current at the boundary surface between the metal and the electrolyte. There the ions of the electrolyte separate out, and cause changes of the most manifold kind.

The simplest case occurs when the metal plates are surrounded by the solution of a salt which contains the same metal, for such a system scarcely exhibits the phenomenon of polarisation at all; such electrodes are 'unpolarisable.' The reason is that in this case the changes occurring at the electrodes do not change the condition of the bounding surfaces. If, for instance, we have zinc in zinc sulphate, zinc is separated out at the cathode, and this combines with the metal present without changing it, and at the anode SO_4 separates out, which then dissolves zinc and forms zinc sulphate. The only effect is that the zinc sulphate solution becomes more concentrated at the anode, and accordingly a small concentration-current can be observed, whose electromotive force is, however, very inconsiderable.

Such a system of unpolarisable electrodes differs from all similar combinations in that it allows any, even the smallest, current to pass through. Polarisable electrodes do not behave thus. If, for instance, two platinum plates are placed in dilute sulphuric acid, and a current of small electromotive force—say, 0·1 volt—is allowed to pass, we observe by the galvanometer that at first a motion of electricity takes place, but that this ceases after a very short time. It is a phenomenon such as a condenser exhibits on being charged, with this difference, that the capacity of such electrolytic condensers appears to be very great. On increasing the electromotive force, a corresponding quantity of electricity answering to a greater charge of the condenser always enters, but no permanent current is produced until the electromotive force is somewhat more than 2 volt; then a more copious passage of the current suddenly takes place, and simultaneously gaseous oxygen and hydrogen appear at the electrodes.

We must, therefore, represent the phenomenon to ourselves in the following way. Between the electrolyte and the platinum plates there exists originally some one difference of potential, and in consequence the double layers form there. Now, on allowing the electromotive force to act, on the one side the difference of potential of the double layer is increased, on the other it is diminished. The corresponding process to this is the condensing charge. On increasing the difference of potential, there is a moment at which the condenser no more isolates under the influence of the electro-static effects; a passage of electricity from the metal to the ions (or *vice versâ*) occurs, corresponding to the disruptive discharge of the condenser, and the ions, deprived of their electric charges, separate out. When sulphuric acid is the electrolyte, the ions are H_2 and SO_4; the latter substance is not stable, and reacts with the water present to form sulphuric acid and oxygen, the latter escaping in the gaseous state.

From this we see that a difference of potential of definite magnitude must exist when the electricity is to leave an ion in order to travel to a metal; until this difference of potential is reached, the system acts at the electrode like an isolator. But why does this not occur with unpolarisable electrodes? The answer to this question follows from the consideration of the processes occurring at these electrodes. Let us again take zinc plates in zinc sulphate, and let us lead positive electricity into one plate. This electricity can at once enter into the solution, by using as its vehicle a corresponding number of zinc atoms, which travel with it as positively charged zinc ions. At the other zinc plate an equal number of zinc ions can also deposit at once, and since there exists no difference of potential between zinc and zinc these can at once deliver up their electricity. Here, therefore, no cause exists for condensing effects. It is not, however, as if no difference of potential existed between the metals and their solutions; such differences, in fact, are present, and hence also corresponding double layers are formed, which at one side are made up of ions. But these do not act as condensers, free communication of their ions between the metal and the electrolyte being possible, and consequently the difference of potential, independent of the current, maintains itself at an unaltered value.

Beside the unpolarisable electrodes and those polarisable at both sides, there still exist combinations in which polarisation occurs only at one side, mostly at the cathode. This takes place, for instance, with copper plates in dilute sulphuric acid. At the cathode, when the electromotive force is sufficient, hydrogen separates out, just as it does at a platinum plate. But at the anode, on the other hand, copper sulphate is formed by the ion SO_4 acting on the copper—*i.e.* the ion SO_4 need not give up its negative electricity there, since in its stead positive electricity fixed to copper comes out of the plate. Hence, no polarisation occurs here.

From what has been said an explanation follows of the cause of the polarisation current, which occurs after breaking the primary current and connecting both plates in the opposite direction. It is, in brief, the discharge of the electrolytic condenser. Looking at the process more in detail, we see that when the charge in the double layers is formed, the electricity led in has remained in the electrodes, equal quantities of the opposite electricities having collected from the electrolyte on the electrodes—the electricity being, of course, bound to the ions. On the primary current being broken, and the electrodes being connected with each other, the electricities present in these neutralise each other, and the ions, which are no longer fixed, form the carriers of the current in the electrolyte. This lasts until the original condition of equilibrium has re-established itself.

In accordance with what has been said, the measurement of galvanic polarisation refers almost exclusively to the maximum value it can assume, or to the value of the difference of potential at which the double layer condenser no more isolates.[1] The measurement of this quantity is somewhat difficult; because, when carrying out the simple experiment indicated above—*i.e.* when increasing the primary current up to decomposition, interrupting it, and afterwards connecting the electrodes with an electrometer—we observe that (in consequence of the secondary effects) the electromotive force of polarisation decreases very rapidly. We are, therefore, not sure whether a considerable portion of the polarisation has not already been lost in the time which elapses before the measurement. But there exists a means of obtaining information concerning the magnitude of the possible error. If the change of connections is carried out more and more quickly, increasing values at first are observed. But these approach

---

[1] It must be observed that complete isolation does not occur; a small amount of percolation of electricity takes place when the maximum value is not reached. But, as Helmholtz has shown, this phenomenon is a consequence of electrolytic convection, and is of a secondary character.

to a maximum, and when the number of current reversals reaches about 100 per second a further rise in the velocity no longer produces an increase, as was found by Raoult (*A. Ch.* [4] 2, 326), and the value observed under these conditions may be regarded as the correct one.

Other methods are based on making measurements of current strengths and resistances in the primary circuit, and on calculating from this the electromotive force of polarisation. These become uncertain by the fact that, owing to the processes occurring at the electrodes, the resistance of the cell undergoes variations during the passage of the current, which variations cannot be determined. Finally, we can use electrometric methods, by measuring the difference of potential between the electrode to be polarised and an auxiliary electrode through which no current passes, both before closing the circuit and while the current passes; the difference between the two magnitudes is the polarisation required. But difficulties, which have not yet been removed, appear in the practical application of this ingenious method, which was pointed out by Fuchs (*P.* 156, 158).

Because of these difficulties only a small number of trustworthy measurements of the electromotive force of the maximum polarisation have as yet been made. Consequently, no certain relations with chemical conditions have been discovered as yet.[1] Though an attempt has been made to calculate the electromotive force of polarisation in a manner similar to that of the galvanic cell, from the thermal effects appertaining to it, the same objections can be raised against it as in the former case (p. 213): the observed electromotive force is generally different from that calculated.

It is especially remarkable that the maximum forces of polarisation corresponding to one and the same chemical process may be very different according to the nature of the metal. If we form galvanic cells of zinc, dilute sulphuric acid, and different metals—such as copper, silver, gold, platinum—or of charcoal, and if we close the circuit in the cells, the same process occurs in all. zinc sulphate is formed, and, to make up for it, hydrogen is expelled from the sulphuric acid. The latter appears at the metal, and polarises it. It is found that the electromotive forces of these cells, even after they have completely polarised themselves, are distinctly different; according to the nature of the second metal, a greater or less portion of the energy liberated by the reaction $Zn + H_2SO_4 = ZnSO_4 + H_2$ is transformed into electrical energy.

The cause of this can be understood after what has already been explained. The electricity must overcome unequal differences of potential in passing from the H ions to the different metals; hence different portions of the total available energy are used, and only the residue of this energy finds its expression in the electromotive force of the cells. We see, then, that the electromotive force cannot possibly bear the simple relation to the heat of reaction which was formerly supposed to be the case. But it is possible that the equation of Gibbs and Helmholtz (p. 214) is applicable to galvanic polarisation also; if this is so we shall be able, from a knowledge of the electromotive force and its changes with the temperature, to draw conclusions as to the thermal changes due to the processes which primarily participate in the polarisation. W. O.

VI. FREEZING-POINTS OF SOLUTIONS, METHODS BASED ON; *v.* MOLECULAR WEIGHTS, vol. iii. p. 417; and ELECTRICAL METHODS, this vol. p. 186.

VII. OPTICAL METHODS.—**Section 1: REFRACTION AND DISPERSION.** When a ray of light passes at an angle from a rarer into a denser medium, it is always reflected towards the perpendicular, the sine of the angle of incidence being in a constant ratio to the sine of the angle of refraction, namely the ratio of the velocities of wave propagation in the two media. This constant ratio is called the index of refraction, and is generally represented in England by the Greek letter μ, and on the Continent by n: $\mu = \frac{\text{sine } i}{\text{sine } r}$. The angle of incidence being in such case greater than the angle of refraction, the index of refraction will be greater than 1. The reverse will be the case when the ray passes from a denser to a rarer medium.

The refraction of a ray of light is, however, always accompanied by another phenomenon—*dispersion*, as the ray is made up of a number of vibrations of different velocities which are affected diversely in passing from one medium to another. This causes the ray of common or white light to be spread out into a number of coloured rays corresponding to vibrations of different rapidity. In all precise determinations, therefore, a definite point of the spectrum thus formed must be measured for refraction, and two such points for dispersion. The work of early observers on the refraction of light is usually wanting in precision in this respect, the records being commonly described as having reference to the bright or yellow part of the spectrum, or to the extreme red; while they furnish no data at all for calculating the dispersion. Moreover, as each colour occupies a certain breadth in the spectrum, and the boundaries of the colours are not well defined, it is by no means certain that two observations made on the same colour will refer to exactly the same part of the spectrum. In more recent observations the most conspicuous lines of the solar spectrum, such as A, D, F, H, are adopted, or, if artificial light be used, the α, β, and γ lines of the hydrogen spectrum; these are recorded as μ_A, μ_D, &c.; μ_α. μ_β, μ_γ. The greater part of the English data of recent times are given for the solar lines, while foreign observers have generally adopted the hydrogen lines.

Refraction and dispersion equivalents. The index of refraction, minus unity, when divided by the relative density (d) and multiplied by the atomic weight if an element is examined, or by the molecular weight if a compound is examined (P), is usually represented by the formula $P\frac{\mu - 1}{d}$ in England and $P\frac{n - 1}{d}$ on the Continent, and is termed the refraction-equivalent. It will be expressed in this article by the simple letter R. When Lorenz's formula is used,

---

[1] See, however, a recent investigation by M. Le Blanc (*Z. P. C.* 8, 299).

$\left(\frac{\mu^2-1}{\mu^2+2}\right)\frac{P}{d}$, the refraction-equivalent so calculated will be distinguished as R. The part of the spectrum to which the observation refers will be indicated by adding the sign for infinity, or the letters of the solar or other lines observed, as R_∞, R_A, R_a, &c. The dispersion-equivalent represents the difference between the refraction-equivalents of two selected portions of the spectrum; thus the dispersion-equivalent for H – A will be expressed as $\frac{(\mu_H-1)}{d}-\frac{(\mu_A-1)}{d}$, or, more briefly $\frac{\mu_H-\mu_A}{d}$, multiplied by P; or R_H-R_A.

The index of refraction of solids is generally ascertained by the method of total reflection, unless they are transparent, and can be cut into the form of a prism; that of gases is best determined by interference. The refraction of liquids is most conveniently arrived at by placing the substance in a hollow prism, with sides of plate glass; on the prism being so adjusted that the incident and emergent rays make equal angles with the refracting surfaces, the minimum deviation will be arrived at. Let D be the deviation, *i* and *r* the angles of incidence and refraction, and *a* the refracting angle of the prism; then

$$\frac{\text{sine } i}{\text{sine } r}=\frac{\text{sine } \frac{1}{2}(a+D)}{\text{sine } \frac{1}{2}a}=\mu.$$

Newton, acting upon the emission theory, proposed $\frac{\mu^2-1}{d}$ as representing the absolute refractive power of any substance, and this formula met with general adoption till recent times. Gladstone and Dale (*T.* 1863), as the result of a long series of experiments with different substances at various temperatures, found that the refractive index, minus unity, multiplied by the volume, gave nearly a constant. To $\mu-1$ they accordingly gave the name of 'refractive energy' as really representing the influence of the substance itself on the rays of light; and to $\frac{\mu-1}{d}$ that of 'specific refractive energy.' This empirical formula has been adopted by most subsequent investigators; and Sutherland (*P. M.* [5] 27, 141) has lately advocated it on mathematical, as well as on physical, grounds. It holds its position side by side with the theoretical formula we have now to consider.

Lorenz's formula. H. A. Lorentz, of Holland (*W.* 9, 641), and L. Lorenz, of Copenhagen (*W.* 11, 70), came almost simultaneously to the conclusion, from purely theoretical considerations, based, in the case of the former, on the electro-magnetic theory, that $\frac{\mu^2-1}{(\mu^2+2)d}$ must express the relation between the velocity of the transmission of light and the density of the medium through which it is propagated. Landolt (*B.* 15, 64) tested the comparative merits of this formula, and that which he had previously adopted—viz. $\frac{\mu-1}{d}$—and found that so far as liquids were concerned there was nothing to choose between them, but that Lorenz's formula showed much less difference between the specific refractive energy of a liquid and that of its vapour. This is shown in the following table, in which it will be also noticed that the difference with the rise in temperature is uniformly plus in the one case, and minus in the other. Weegmann (*Bonn.* 1888) experimenting at 10°, 20°, and 30°, noted the same rise in the one case and fall in the other.

Substance	State	Temp.	$\frac{\mu_D-1}{(\mu_D+2)d}$		$\frac{\mu_D-1}{d}$	
Water .	Liquid	10°	0·2062		0·3338	
	"	20°	0·2061	0·0001	0·3336	0·0002

In the case of liquid and solid phosphorus, as well as of other highly refractive bodies, the empirical formula appeared to give the best results. Landolt also found the simpler formula best adapted to his process of optical analysis subsequently described. But while he found that the refraction-equivalents (*i.e.* the specific refractive energy multiplied by the atomic weight in the case of elements, or by the molecular weight in the case of compounds) of substances calculated by Lorenz's formula are about one-third smaller than the numbers calculated by the formula previously adopted by him, the values which he obtained for the elements carbon, oxygen, hydrogen, and chlorine did not bear the same proportion. Adopting Brühl's figures for R_a (as described later on), the values according to Lorenz's formula vary from about ½ to ¾ the values found by using the other formula. Thus:—

	Old Formula	Lorenz's Formula
Carbon	5·0	2·48
Hydrogen	1·3	1·04
Oxygen, alcoholic . .	2·8	1·58
" aldehydic . .	3·4	2·34
Chlorine	9·8	6·02
Increase for double carbon bond	2·4	1·78

Brühl, however, in 1886 (*A.* 235, 1), maintained that the statement of Landolt, that the two formulæ lead practically to the same conclusions in respect to chemical constitution and the refraction of light, cannot any longer be accepted in its general sense. In this paper Brühl contended that the expression of the molecular refraction hitherto used—viz. $P\frac{\mu-1}{d}$, is generally adapted only to the paraffinoid series of carbon compounds, and for unsaturated compounds of weak dispersive power; and that in these cases even the results are not altogether satisfactory. For the investigation of the relations between the refractive power and the constitution of bodies, Brühl claimed that in future Lorenz's formula must be used. The tables appended to the paper certainly show better proportionate results for R_a by this formula, especially in the case of the most dispersive substances; but in using these tables it must be borne in mind that the values assigned to the elements under the two formulæ are not strictly comparable. Nasini (*Lincei, Rc.* 3, 128) stated that he and Bernheimer did not consider that, from a chemical point of view, any great preference should be given to Lorenz's formula over the formula $\frac{\mu-1}{d}$, as the newer formula was insufficient to represent every relation between the chemical constitutions of the substances and their refractive powers. Ketteler does not accept the Lorenz formula as altogether satisfactory; in place of it he has proposed $\frac{\mu^2-1}{(\mu^2+x).l}$, where x is a variable quantity depending on the nature of the substance, but averaging about 3·5 instead of 2. Sutherland (*P. M.* [5] 27, 141) objects to Lorenz's formula on the ground that it assumes a mean wave length, whereas the wave length must vary in passing from ether to matter; and he maintains that while the formula holds good for both the liquid and gaseous states, it fails when change of density is produced by change of pressure. On the other hand, he thinks that Gladstone's formula meets the last requirement, but fails to bridge over the great gap in density between liquid and vapour. Ketteler (*Z. P. C.* 2, 905) suggests an equation of the form $(n^2-1)(v-\beta)=M$, where β is the volume actually occupied by the ponderable molecules, v that of the space in which they are contained, and M a molecular function depending on the constitution of the medium. M may have one of two values, both of which are definite constants, the one for the liquid and the other for the gaseous state. The value of β may be obtained by varying the temperature, the pressure, or the constitution of the media examined. Sutherland says that this formula gives for compressibility results less satisfactory than those given by that of Gladstone.

Zehnder (*W.* 34, 91) investigated the influence of pressure upon the index of refraction of water at different temperatures, and on comparing the results with the co-efficient of compressibility, he came to the conclusion that the formula $\frac{\mu-1}{d}$ was practically exact—much more so than that of Lorenz. Röntgen and Zehnder (*W.* 44) have since applied the same inquiry to CS_2, and C_6H_6, ether, and a series of alcohols, with the result that in the cases of all these substances neither formula is sufficiently exact, the experimental figures occupying very nearly the mean place between those given by the two formulæ.

Perkin (*C. J.* 61, 287) in studying magnetic rotation at widely different temperatures, observed a slight reduction as the temperature was raised. Dale and Gladstone (as long ago as 1868) had observed that the specific refractive energy of substances was similarly affected; Nasini and Bernheimer (*G.* 15, 59) in 1885, and Ketteler (*W.* 33, 506, 662) in 1888, also found small differences in the same direction. Perkin accordingly made a series of experiments to see if the changes in $\frac{\mu-1}{d}$ due to temperature vary with different classes of substances, as they do in the case of the magnetic rotation. The results seem to corroborate this, though not very definitely. On trying Lorenz's formula, he found the refraction rise with increase of temperature, and he came to the conclusion that this formula is not suitable when dealing with high temperatures.

Guye (*Ar. Sc. Genève*, 23, 197, 204) pointed out a relation between the constants of the equation of Van der Waals and that of the formula of Lorenz for the refraction of light. He maintained that the relation of the absolute critical temperature to the critical pressure, which he termed the 'critical co-efficient,' is proportional to the molecular refraction, and that it furnishes a valuable means of determining the molecular constitution of bodies at the critical point. By a comparison of the data given by a number of observers for forty different substances he obtained the result that the critical co-efficient (K) is in proportion to R_∞ as 1 to 1·8. The experimental difficulties connected with the determination of K, and the fact that Guye had not always the data for reducing R observed to R_∞, rendered the final results less uniform than they might be otherwise; but the extreme range of his factor varied from 1·6 to 2·0, giving 1·8 as a mean. Guye found, however, certain classes of bodies which gave a different factor to that above mentioned. Such gases as O, N, and CO, gave a factor ranging from 1·1 to 1·4. Water gave 1·1, and methylic alcohol 1·1 to 1·2. He also recorded some which are exceptionally high, but in most of these cases the results of the experiments seem untrustworthy in consequence of chemical action having taken place. Having determined his factor, he was able to divide by it the recognised refractions of the elements according to Brühl, and so to get what he termed the 'atomic critical co-efficient,' from which he could build up the critical co-efficient of any substance of which the theoretical constitution was determined.

Dispersion formulæ. As the observations of Gladstone extended to the solar line A, his calculations were but slightly affected by dispersion; whereas nearly all the Continental observers have used the hydrogen light, and have no actual measurements below the line α. They have, therefore, usually sought to get rid of the effect of dispersion by adopting one or other of the suggested formulæ for calculating the theoretical ray of infinite wave length, and have worked out their results both for the observed line α, and for the assumed limit. The simplest of these methods, and on that account the one most generally adopted, is that of Cauchy. It is usually expressed by the formula

$$\mu = A + \frac{B}{\lambda^2} + \frac{C}{\lambda^4} + \dots$$

in which λ represents the wave length of any given line of the spectrum. As this formula contains three unknown quantities, it requires for their determination three simultaneous equations; but the third term is often dispensed with to reduce the amount of calculation required. By the process of elimination, the values of A, B, and C are obtained, A being Cauchy's co-efficient of refraction, and B and C the co-efficients of dispersion. This theory accords fairly with the experimental data for substances of moderate dispersive power, though by no means well with the data for substances of high dispersive power, such as oil of cassia. Wüllner (*A.* 133) considered that this formula was sufficiently exact for bodies of low dispersive power when two constants were used; but that for highly dispersive substances, such as carbon disulphide, it was necessary to go to the third term, as the difference between the observed value of μ_β and that calculated from μ_α and μ_γ amounted to as much as 0·0022; while on using three terms the calculation was correct to the fourth decimal place. He also tried the formula of Christofle

$$n = \frac{n_0\sqrt{2}}{\sqrt{1+\frac{\lambda_0}{\lambda}} + \sqrt{1-\frac{\lambda_0}{\lambda}}}$$

in which n_0 and λ_0 signify two selected constants, and n is the corresponding index of refraction of the wave length λ; this also gave results which were not sufficiently accurate. Taking the observed indices for the lines α and γ of carbon disulphide at 0° as 1·631066 and 1·692148, this formula gave 1·669397 for β, while the observed value was 1·669076. At 20° the calculated value for β was as much as ·000494 too high. Langley (*P. M.* [5] 17, 194) has discussed the relative merits of Biot's, Cauchy's, and Redtenbacher's formulæ, and has come to the conclusion that while each of them is sufficiently exact within the limits of the visible spectrum, they soon begin to give too small results for μ when that limit is passed. Biot's formula

$$\frac{1}{n^2} = a + b\left(\frac{n^2}{\lambda^2}\right) + c\left(\frac{n^4}{\lambda^4}\right) + k\left(\frac{\lambda^2}{n^2}\right)$$

gives more trustworthy results than either of the others.

Redtenbacher's formula $\frac{1}{n^2} = a + b\lambda^2 + \frac{c}{\lambda^2}$ has the serious objection that it reached a minimum at a point corresponding to $n = 1{\cdot}5647$ in the prism which he employed, so that for every value of n greater than 1·5647 it gave two different values for λ. Langley has experimentally determined wave lengths in the invisible prismatic spectrum far beyond the extreme limit possible according to Cauchy's formula. Brühl, after working out his results for R_∞ as well as for R_α, has latterly (*A.* 235, 1; 236, 233) come to an adverse conclusion as to the utility of Cauchy's co-efficient of refraction for getting rid of the effect of dispersion, and he even asserts that when three terms are used the results are less to be relied upon for this purpose than when two terms only are employed. The following table shows the differences in Cauchy's A when calculated with two and three terms respectively, from the observed indices μ_α and μ_γ in the former case, and from μ_α, μ_β, and μ_γ in the latter; and also μ_β as observed, compared with the same index of refraction as calculated by Cauchy's formula from μ and μ_γ, showing in this case a difference of from one to five units in the third place of decimals:—

Substance	Cauchy's A		μ_β	
	2 terms	3 terms	Observed	Calculated
Benzoyl chloride .	1·51906	1 52700	1·56964	1 57097
Orthotoluidine .	1·53715	1·54160	1·58945	1·59069
Cinnamic alcohol .	1·54307	1·55253	1·59993	1·60151
Aniline . . .	1·54741	1·55689	1·60434	1·60592
Furfurol . . .	1·48269	1·49816	1·54566	1·54824
Cinnamic aldehyde .	1·55966	1·58256	1·65090	1 65622

In the case of substances of small dispersion, Brühl regards the use of Cauchy's formula as superfluous; with substances of medium dispersion, the results are generally preferable to those for the line α, though not to any great extent; but with substances of great dispersive power the differences are too great to be neglected in considering questions of chemical structure.

Nasini (*Lincei, Atti*, 18 [3]) comes to the same conclusion, that Cauchy's co-efficient of refraction ought to be rejected in studies of this nature, and that his co-efficient B is still more misleading if it be regarded as a measure of dispersion. N. (*Lincei, Atti*, 19 [3]) had already tested the merits of several formulæ, and given the preference to that of Lommel as affording better results than those arrived at by Cauchy's formula with two terms. The following table will show the differences between μ_β as observed, and as calculated by these two formulæ:—

Substance	μ_β observed	Calculated		Difference	
		Cauchy	Lommel	Cauchy	Lommel
Benzene. .	1·51339	1·51404	1·51369	0·00065	0·00030
Aniline . .	1·60434	1·60592	1·60522	0·00158	0·00088
Methyl-α-naphthol .	1·64597	1·6477	1·64678	0·00173	0·00081
Dimethyl-naphthalene	1·63200	1·6330	1·6324	0·00100	0·00010

Weegmann (*Bonn.*, 1888) gives reasons why Cauchy's formula for the limit of the spectrum is not to be relied upon; and maintains that his B, or co-efficient of dispersion, must not be taken as a measure of dispersive power, but that it should in any case be divided by the relative density.

Helmholtz has proposed the formula

$$n^2 - 1 = Q\frac{\lambda^4}{\lambda^2 - \lambda^2_m} - P\lambda^2$$

in which n and λ represent the index of refraction and the corresponding wave length, and Q, P and λ^2_m are three constants dependent upon the nature of the medium. Ketteler has subsequently proposed another, viz.

$$n^2 - 1 = \frac{A}{\lambda^2 - B} + \frac{C}{\lambda^2 - D} + \dots$$

Brühl has tested the comparative merits of both these formulæ, as well as that of Cauchy. Taking Gladstone and Dale's observations of a solution of phosphorus in carbon disulphide, he calculated the values of the lines B, D, F, and G from the observed values of A, E, and H, and again those of A, B, E, and G from those of D, F, and H. The following table shows the differences in the two cases between the observed and calculated values (*A.* 236, 233);

Line	λ	μ observed	Cauchy	Helmholtz	Ketteler	Cauchy	Helmholts	Ketteler
A	7·606	1·9209	...	...	...	+19	+48	+108
B	6·372	1·9314	−3	−5	+2	+ 9	+21	+ 47
D	5·893	1·9527	−2	−4	...	...	...	...
E	5·271	1·9744	...	...	−4	−5	−6	−9
F	4·862	1·9911	+8	+9	...	...	...	...
G	4·304	2·0361	+1	+2	−7	−7	−6	...
H	3·956	2·0746	...	...	...	...	...	...

Dispersive power. The difference between the indices of refraction of the rays of the spectrum of any refracting medium is termed the 'dispersion'; and by the dispersive power of a substance is expressed the ratio of the co-efficient of dispersion to the index of refraction of the mean ray minus unity. Thus taking the full length of the visible spectrum as extending from A to H, and F as the mean ray, the dispersive power would be represented by the formula, $\frac{\mu_H - \mu_A}{\mu_F - 1}$.

Ketteler (*Theoretische Optik*, Braunschweig, 1885) has proposed two formulæ for dispersion based upon theoretical grounds:

$$\frac{\mu_n{}^2 - 1}{\mu_m{}^2 - 1} \text{ and } \frac{\mu_n{}^2 - \mu_m{}^2}{\mu_n{}^2 - 1}$$

when n is a ray more refractive than m. Costa (*G.* 19) regards these as having the advantage over the formula $\frac{\mu_n - \mu_m}{d}$ on account of their being independent of the density of the medium.

Early experiments. Newton, Herschel, Young, Wollaston, Brewster, and others determined the indices of refraction of a large number of solids and liquids, in most cases for the yellow or brightest part of the spectrum. The index for the solids ranged from 1·111 for tabasheer to 2·974 for chromate of lead, and for liquids and soft solids from 1·0570 for ether expanded by heat to thrice its volume, to 1·678 for disulphide of carbon, and about 1·8 for chloride of antimony (*Encyc. Brit.*, 8th edit. Optics, 558).

Arago and Fresnel applied the method of interference to the comparison of the refractive indices of moist and dry air, with the result that moist air was found to be rather less refractive than dry air. Dulong determined the indices of refraction of a considerable number of gases and vapours.

Dulong, together with Arago, Biot, and others, adopted the formula of Newton $\frac{\mu^2 - 1}{d}$, and came to the following conclusions; that the refractive power of a mixture of gases is equal to the mean of the refractive powers of the constituent gases calculated for the pressure to which each gas is actually subjected in the mixture, and that the refractive power of a compound gas is not equal to the mean of those of the component gases, but is sometimes greater and sometimes less.

Höck also found this formula to apply to some mixtures of liquids, and Schrauf (*P.* 133, 479) has more recently supported the same mode of calculating the refractive power; but Ketteler (*P.* 124, 390) found that liquid sulphurous acid was not accordant with the known refraction of the gas as arrived at by the formula $\frac{\mu^2 - 1}{d}$, while the two came into agreement when he adopted the modern formula for the specific refractive energy $\frac{\mu - 1}{d}$.

Jamin (*A. Ch.* [4] 3, 49) made careful experiments on the influence of the presence of aqueous vapour in the atmosphere upon the refractive index, and he found that the difference between the refractive indices of dry air and air saturated with aqueous vapour was only ·000000726, a quantity so small that it may be safely neglected in the calculation of atmospheric refraction for astronomical purposes.

Ketteler (*B. B.* 1865) adopted Jamin's interference refractor for the measurement of the index of air, CO_2, CN, H, and SO_2, for the line D. He calculated the lithium and thallium lines from the wave length of the sodium line, according to the proportional number of rulings that coincide, it being found that this is independent of density and is a true function of the wave lengths.

RELATIONS BETWEEN PHYSICAL AND CHEMICAL PROPERTIES AND REFRACTION OF LIQUIDS.

Dale and Gladstone (*T.* 1858. 887) made an elaborate series of experiments on what they then termed the sensitiveness of liquids, or the effect of temperature on the refractive index. The principal conclusions they arrived at were that both the index of refraction and the length of the spectrum, $\mu_H - \mu_A$, diminish as the temperature rises, and that the sensitiveness of a substance is independent of its specific refractive or dispersive power. These conclusions were the result of observations on CS_2, Et_2O, H_2O, P, alcohols, &c. The following table and the table on p. 226 give the data for CS_2 and H_2O:—

Carbon disulphide (b.p. = 43°)

Temp.	μ_A	μ_D	μ_H	Sensitiveness	$\mu_H - \mu_A$	Dispersive power
0°	1·6217	1·6442	1·7175	0·0045	0·0958	0·1489
5°	1·6180	1·6397	1·7119	0·0051	0·0939	0·1467
10°	1·6144	1·6346	1·7081	0·0043	0·0937	0·1477
15°	1·6114	1·6303	1·7035	0·0042	0·0921	0·1462
20°	1·6076	1·6261	1·6993	0·0041	0·0917	0·1463

42·5°	1·5900	1·6082	1·6778		0·0878	0·1443

The sensitiveness is reckoned from the indices of the line D, and the dispersive power represents $\frac{\mu_H - \mu_A}{\mu_D - 1}$. The sensitiveness indicates an anomaly in water, which has also been observed by others.

Gladstone and Dale (*T.* 1863. 317) extended the same inquiry to the following five points:—(1) the relation between sensitiveness and the change of volume by heat; (2) the refraction and dispersion of mixed liquids; (3) the refraction, dispersion, and sensitiveness of different members of homologous series; (4) the

Water

refraction, dispersion, and sensitiveness of isomeric liquids; (5) the effect of chemical substitution on these optical properties. As to the first point of the inquiry, they came to the conclusion that the specific refractive energy $\left(\frac{\mu-1}{d}\right)$ is a constant not affected by temperature. They made the reservation, however, 'that there is some influence, arising wholly or partially from dispersion, which gives rise to the slight progression of most of the calculated products, and perhaps to the non-inversion of the sensitiveness of water at 4°, remarked on already by Jamin and ourselves.' As to the second point of inquiry, it was found 'that the specific refractive power of a mixture of liquids is the mean of the specific refractive powers of its constituents,' subject to some slight exceptions, as in the case of sulphuric acid and water. The inquiry into the refraction, dispersion, and sensitiveness of different members of homologous series showed a progressive increase in the specific refractive energy as the series advanced; but that the influence of each addition of CH_2, which is observable throughout the series of the methyl group, does not necessarily hold good with reference to substances of quite another type. The observations on isomeric bodies showed that some of them are widely different in their optical properties; but that those which have a close chemical relationship show an identity in their optical properties also. In the last branch of the inquiry it was sought 'to determine the amount of change in the optical properties which results from a replacement of one element by another, the type remaining the same,' in order to 'attain to a knowledge of the influence of the individual elements on the rays of light transmitted by them.' The general conclusion of Gladstone and Dale was that 'every liquid has a specific refractive energy composed of the specific refractive energies of its compound elements, modified by the manner of combination, and which is unaffected by change of temperature, and accompanies it when mixed with other liquids.' This opened up a question which has since occupied the attention of many observers.

Landolt (*P.* 117, 122, 123) took up the inquiry, adopting the formula $\frac{\mu-1}{d}$ used by Gladstone and Dale, and applied it in the first instance to an investigation of the values of C, H, and O. He simplified the investigation by multiplying the specific refractive energy by the molecular weight of the compound, which gave P $\frac{\mu-1}{d}$ as the molecular refractive power, or refraction-equivalent, terms which had already been applied by Berthelot and Schrauf to the formula P $\frac{\mu^2-1}{d}$. By comparing series of homologous compounds, acids of the series $C_nH_{2n}O_2$, alcohols of the series $C_nH_{2n+2}O$, and esters of the series $C_nH_{2n}O_2$, L. obtained the increment due to each addition of CH_2 as shown in the following selection from his data:—

—	Substance	S.G. $\frac{18}{18}$	μ	$\frac{\mu_a-1}{d}$	R_a	Diff. CH_2

	Ethyl valerate	0·8674	1·3950	0·4554	59·20	

The mean of Landolt's comparisons gave the value R = 7·60 for CH_2. Dealing in the same manner with compounds differing by one atom of carbon, by two atoms of hydrogen, and by one atom of oxygen, respectively, he assigned to the several elements the following refraction-equivalents; C = 5·00; H = 1·30; O = 3·00. Subsequent investigations would lead one to reject several of the substances which he brought into comparison.

Landolt also adopted a modification of Biot and Arago's formula for mixtures of gases, by substituting *n* for n^2 throughout, so that

$$\frac{N-1}{D}P = \frac{n-1}{d}p + \frac{n'-1}{d'}p' + \ldots$$

N, D and P representing the index of refraction, density, and 'molecular weight' of the mixture, and the small letters the same values of the several substances forming the compound. In this manner he calculated the value of n_a or μ_a, for mixtures of liquids as shown in the follow-

ing table. It will be seen that the calculated and observed values correspond very closely.

—	p	Observed d	Observed μ_a	Calculated μ_a

Halogen compounds. Landolt's values for the refraction-equivalents of C, H, and O are:

Carbon . .	R_∞	4·86	R_a	5·00
Hydrogen . .	„	1·29	„	1·30
Oxygen . .	„	2·90	„	3·00

Adopting these values, Haagen (*P.* 131, 117) deduced values for Cl, Br, and I from some of their organic liquid compounds, and then deduced values for other elements from observations of R for their chlorine compounds. The following are the results he obtained for R_∞ and R_a:—

Element	R_∞	R_a
Chlorine . . .	9·53	9·79
Bromine . . .	14·75	15·34
Iodine	23·55	24·87
Sulphur . . .	14·74	16·03
Phosphorus . . .	14·60	14·93
Arsenic . . .	18·84	20·22
Antimony . . .	—	25·66
Silicon . . .	7·81	7·90
Tin	18·64	19·89
Sodium . . .	4·71	4·89

Refraction-equivalents of the elements. Gladstone (*T.* 159, 13; *Pr.* 18, 49) applied Landolt's $P\frac{\mu-1}{d}$ to inorganic compounds in order to arrive at the refraction-equivalents of the several elements, and also to determine whether or not any of the elements had more than one definite refraction-equivalent. As most of his observations were made upon crystalline salts, many of which were doubly refracting, Gladstone adopted the plan of dissolving them in water, or alcohol, and deducting from the R of the solution the R due to the solvent. This mode of operation was supported by the consideration that in the cases of rock-salt and sugar, where the refraction-equivalent of the substance has been obtained both in the solid and dissolved condition, it is found to be the same. On comparing a series of salts of K and Na, it was evident that, while the refraction-equivalents of the compounds differed very widely, according to the nature of their negative constituents, the refraction-equivalents of the compounds of Na differed *pari passu* with those of the K compounds, and hence it was concluded that the negative constituent has the same effect on light, whichever metal it is united with. Values were arrived at for forty-six of the elements, a number which has been subsequently somewhat increased; and more recent investigations have led to slight modifications in the figures. The latest list is as follows:—

Element	At. w.	R_A
Aluminium . . .	27·5	7·7
Antimony . . .	120	24·5

Anomalies were pointed out in the refraction-equivalents of the hydracids, and of the benzenoid carbon compounds. With regard to the specific refractive energy it was remarked:—First, hydrogen has more than double the energy of any other element, even in the lowest number that can be assigned to it. Second, phosphorus, vanadium, titanium, and sulphur have singularly high energies, and they are substances that present certain chemical analogies. Third, there are several pairs of analogous elements having nearly the same energy; thus bromine and iodine, arsenic and antimony, potassium and sodium, manganese and iron, nickel and cobalt. Fourth, an element in altering its valency alters its energy. Fifth, if the metals are arranged in the order of their energies, they are, with few exceptions, in the inverse order of their atomic weights.

Benzenoid hydrocarbons.—The anomalous refraction and dispersion of the hydrocarbons already referred to was treated in a paper by Gladstone (*C. J.* 23, 147), the tables in which indicated that the values for all these bodies and their derivatives were largely in excess of the normal, calculating R_A of carbon at 5·0. The refraction-equivalents of the typical hydrocarbons were expressed as in the following table; but while the physical fact indicated has been fully verified by subsequent research, the particular numbers in the third column have been modified, and a plus has been assigned to the olefines.

A similar table is given illustrating the increased influence on light of carbon which is combined with two atoms of hydrogen or one of oxygen, in a series of oxidised bodies obtained from essential oils, differing from one another only in the quantity of hydrogen.

Hydrocarbons	Typical Formula	R
Paraffins	C_nH_{2n+2}	Normal

Anthracene	C_nH_{2n-8}	„ + 17

Bedson and Williams (*B. A.* 1881. 155) tested the question whether the specific refraction of a solid body could be determined from the refractive power of its solution as stated by Dale and Gladstone, as this method had been called in question by Janovsky (*Sitz. W.* 82, 148). They found the specific refractive energy for the ray of infinite wave length, calculated from solutions of NaCl, $Na_2B_4O_7$, H_3BO_3, and $NaPO_3$ to be in substantial accord with the results derived from observations on the solids. They also found that the specific refraction of liquid phenol is practically identical with the value calculated from solutions in alcohol and in acetic acid.

In taking the index of refraction of solid $NaPO_3$, B. and W. immersed it in a liquid of greater refractive power, and then added a feebly refractive liquid until the refractive power of the mixture appeared to be the same as that of the solid suspended in it. The index of refraction of the mixture was then determined. The result being found satisfactory, the prisms of rock-salt and of fused borax were also tried by the same process, as well as in the ordinary way, and with similar results.

Double values of carbon and oxygen. Brühl, in 1879 and 1880 (*A.* 200, 139; 203, 1, 255), conducted a long investigation into the chemical constitution of carbon compounds in reference to their relative densities and their power to refract light. Taking up the observations of Gladstone, and also referring to some of the anomalous results in the tables issued by Landolt, whose mode of investigation suggested that the grouping of the atoms exercised a certain influence upon the refraction of light, Brühl set himself to inquire: What is the typical peculiarity which must be common to all the bodies that refract light in an abnormal manner? He usually determined the indices for the three H lines, μ_α, μ_β, and μ_γ, and for the Na line μ_D, and calculated the refraction-equivalents both for the line α, and for Cauchy's A, viz. R_∞. The following table is so arranged that between each horizontal line the first-named substance has the highest molecular weight, while those below differ only in having a smaller quantity of hydrogen, and, therefore, contain doubly-linked carbon atoms.

It will be observed that the density, the index of refraction, and the co-efficients of refraction and dispersion of Cauchy always increase with the diminution of H, and that the loss in specific refractive energy which is suffered by the disappearance of two atoms of H is at least fully made up by the consequent double linking of the carbon atoms. For the calculated values of the refraction-equivalents, Brühl has adopted the following values for the elements, viz.—for R, C=5·0, H=1·3, O=3·0, Cl=9·8, Br=15·3,

Substance	Formula	S.G. $\frac{20^\circ}{4^\circ}$	μ	Cauchy's A	Cauchy's B	$\frac{\mu_\alpha - 1}{d\frac{20^\circ}{4^\circ}}$	R_α Observed	R_α Calculated
Propyl alcohol	C_3H_8O	0·8044	1·38315	1·37542	0·34630	0·4767	28·60	28·4

N = 5·8; the first three being the values given by Landolt, the two halogens those by Haagen, and that for N being determined by Brühl himself. From the observations recorded in the foregoing table and others, Brühl has arrived at the following conclusions:—That the closing of the chain of atoms in the form of a ring, with which so marked an increase in the density and index of refraction is associated, exercises a very special influence on the power of the substances to disperse light; that the mol. refraction of the substances in which the existence of one or more pairs of doubly-linked carbon atoms is recognised is greater than the sum of the refractions of the constituent atoms by 2·0 in the case of Cauchy's limit, and 2·3 in the case of the line H_α for each such pair. For combinations of the acetylene type, including the propargyl derivatives, he gives a rather lower value, viz.: 1·8 and 1·9 respectively. These data give the following atomic refractions for carbon, viz.—

	R_∞	R_α
C′	4·86	5·00
C″	5·86	6·15
C‴	5·76	5·95

Nasini and Bernheimer (*Lincei, Atti*, 18) do not, however, admit Brühl's views as to the constitution of the propargyl compounds, as well as some of the other conclusions at which he has arrived. They give tables of observations on naphthol compounds, styrol, cinnamic alcohol, anethol, anisol, thymol, and diamylene, and have worked out the results by the two ordinary formulæ for R_α and R_∞, and also for R_∞ and $\mathbf{R}_\infty$, as well as showing the small differences both in specific refraction and specific disperson due to differences in temperature. The principal conclusions at which they arrive are as follows:—The statement that every double bond, and only every double bond, causes the mol. refraction to increase by a constant quantity is not confirmed by complete series of substances, because in compounds containing only four or five double bonds the increase in refraction indicates a much greater number. That the increase in mol. refraction grows step by step as the compounds become poorer in H; but no proportion exists between the increased values and the number of pairs of atoms of H that is lost; nevertheless, a simple relation exists with the other structural changes in the formula, expressed by double bonds, closed chains, &c. That the augmentation increases more or less rapidly from the paraffins to the olefines, and thence to the benzenes, and again to the naphthalenes, but by what law is not evident, and is not capable of expression by our structural formulæ. They consider it established, however, that the principle is approximately valid, that in every series of compounds each atom in the molecule furnishes its fixed contribution of refraction, and that in the paraffin series the mean values of the atomic refractions coincide with those derived directly from the elements themselves. They remark that even in the paraffin series the constancy of the atomic refractions is not absolute; because the more the mol. w. increases the greater is the difference between the calculated and experimental values. For other series the same values no longer apply, being too low, and hence other constants are required.

Kanonnikoff (*Bl.* [2] 36, 557) has published observations confirming Brühl's calculation of the increase due to the double bond between carbon atoms, and of the loss in specific refractive energy due to the elimination of two atoms of hydrogen being counterbalanced by the increase due to the consequent double linking of the carbon atoms.

Landolt (*P.* 117, 122) had determined the refraction of oxygen from a comparison of the refraction-equivalents of various substances the empirical formulæ of which differed by one atom of oxygen; and from acids of the formula $C_nH_{2n}O_2$ by deducting the value of n times CH_2. The results were somewhat discordant, the first series giving a mean value for oxygen of 2·76, and the latter of 3·0. The former of these manifestly represented the atomic refraction of oxygen in hydroxyl; and if oxygen varied in its refraction according to its valency it is evident that a general average resulting from these two modes of determination could not be taken. Brühl shows that, adopting Landolt's second plan for arriving at the value of oxygen in the aldehydes and ketones of the formula $C_nH_{2n}O$, the R_α for oxygen will average 3·4; and that chloral, butyl-chloral, and the oxychlorides give substantially the same result. On the other hand, deducting the refraction-equivalents of the aldehydes from those of their corresponding acids, of the alcohols from the glycols, and of the acids from the oxyacids, he obtains 2·75 as the mean value for oxygen. An approximate result, 2·80, is obtained if, from the ethers, $C_nH_{2n}O_2$, the value of n times CH_2 + the higher value (3·4) for one atom of oxygen be deducted. For oxygen united to carbon by a double bond, Brühl therefore assigns the refraction-equivalent 3·4 for the line α; and for oxygen in hydroxyl, or generally for oxygen united to two other atoms, he gives the value 2·8; he represents the former as O″ and the latter as O′.

$$\text{Hence } C{=}O = 5{\cdot}0 + 3{\cdot}4 = 8{\cdot}4.$$
$$C{-}O = 5{\cdot}0 + 2{\cdot}8 = 7{\cdot}8.$$

Whether, however, the increased result of the double linking of the carbon and the oxygen is due to one of the elements only, or whether both of them share in it, he leaves an open question, though he regards the latter as the more probable. If two atoms of H are removed from a substance without involving the double linking of carbon atoms, as in the case of an alcohol being converted into an aldehyde or ketone, there follows a very marked reduction of the specific refractive energy. This reduction, however, becomes less and less marked as the quantity of C increases in the higher members of the series. When the removal of two atoms of H involves the double linking of the C, the loss of refractive energy is more than compensated by the increase due to the doubly-linked C.

A comparison of a considerable number of isomeric bodies of the paraffinoid series of acids shows that the indices of refraction of the primary and normal compounds are a little greater than those of the secondary and iso-compounds, and that the densities are proportional. In the case of unsaturated compounds of similar empirical composition, however, the double linking of the carbon atoms increases the refractive power more than the density.

In a subsequent paper (*A.* 235, 1), Brühl treated of the molecular refraction of organic liquids of high dispersive power. He arrived at the conclusion that the dispersion of different substances stands in no clearly recognisable relation either to their refraction or chemical constitution; and that it cannot be numerically expressed. This, however, is contested by Gladstone (*Pr.* 42, 401), who, while admitting that there are difficulties in the investigation of dispersion which are not felt in dealing with refraction, still holds (1) 'that dispersion, like refraction, is primarily a question of the atomic constitution of the body: the general rule being that the dispersion-equivalent of a compound is the sum of the dispersion-equivalents of its constituents; (2) that the dispersion of a compound, like its refraction, is modified by profound differences of constitution, such as changes of atomic valency; (3) that the dispersion frequently reveals differences of constitution at present unrecognised by chemists, and not expressed by our formulæ.' Brühl held that the differences which still appear between the calculated and experimental values when Lorenz's formula is used, and which he showed to be less in proportion than when the old empirical formula is used, are principally due to the influence of dispersion, and that they would in great measure vanish if this disturbing cause could be overcome; that with substances with a dispersion equal to about that of cinnamic alcohol the molecular refraction for the line α would serve as a help to the determination of the chemical constitution, but beyond that limit the numerical results are too uncertain to be of use except as collateral evidence; that there is a direct and simple proportion between the number of unsaturated groups of atoms in any compound and the increase of the molecular refraction $\left(\frac{\mu^2-1}{\mu^2+2}\right)\frac{p}{d}$ over the value derivable from the empirical chemical formula; that the effect on refraction of the acetylene combination, which he represents by ≡, is analogous to that of the ethylene, or doubly-linked carbon, =, and that it is somewhat greater, but not twice as great, as the latter.

Gladstone questions Brühl's assumption that both cinnamic alcohol and cinnamic aldehyde have four pairs of doubly-linked carbon atoms, on the ground that they have widely-different dispersions; also that allyl paracresolate and anethol are similarly constituted, for the same reason. He also thinks that the evidence as to the constitution of cymol and hexahydro-naphthalene from Brühl's observations is not conclusive as to the one having three pairs, and the other two pairs, of doubly-linked carbon atoms, seeing that they have nearly the same dispersion. Nasini (*Lincei*, *Rc.* 3, 164) in like manner holds that these particular compounds do not justify the conclusions that Brühl has come to respecting them, and agrees with G. that the dispersion may be a constant, and a much more sensitive one than the specific refraction; and that as such it is affected more and varies more by certain little differences of composition and constitution of which the specific refraction does not feel the influence.

Brühl (*Z. P. C.* 1, 6) maintains that Erlenmeyer's constitutional formula, with five ethylene combinations, correctly represents the structure of naphthalene, and those derivatives in which hydrogen is replaced by monovalent elements. But the results of the observations on which he bases this conclusion all show a larger increment than can be accounted for by this formula; the excess he attributes mainly to the influence of dispersion. In this and all the other inquiries he has adopted Lorenz's formula, and the solar line C, without attempting to get rid of the influence of dispersion by the use of Cauchy's co-efficient of refraction. In the same paper he formulates the following six propositions:—(1) Isomerides of similar atomic arrangement (*Stellungsisomere*) have similar specific and molecular refractive powers; on the other hand, those isomerides which show differences of saturation (*Sättigungsisomere*) have various specific and molecular refractive powers; (2) polymeric combinations never show similar specific refractive energy, or multiple molecular refraction corresponding to the molecular weights; (3) transformations of multiple linkings of atoms into simple ones have as their result a diminution of refraction, equally, whatever the kind of chemical change may be (polymeric or isomeric change); (4) the optical effect of the accumulation of multiple linkings is the same, whether it produces open chains (amylene—diamylene) or ring formations with one or more groups of rings (as in paraldehyde, cymhydrene, menthol, &c. in the one case, and in turpentine and cajeputol in the other); (5) the molecular refraction of a fully saturated body is very nearly that of the sum of the refractions of the atoms of the empirical chemical formula, each of these being reckoned as united by single bonds—all those are to be regarded as saturated bodies in which there is no multiple linking of the atoms, such as the true paraffins, or derivatives of the general formula $(C_nH_{2n+2}) - xH_2$; (6) all unsaturated bodies show an increased refraction which is proportional to the number of ethylene, acetylene, or carbonyl combinations present; the proportion, as a rule, is the more exact the less the substances in question are distinguished by a specially great dispersion. While holding to the opinion that the monovalent elements have virtually each but one refraction equivalent, and that the change of valency in the others is the chief cause of their variable refraction, Brühl considers that exact values cannot be obtained, because the mode of the grouping of the atoms may not be altogether without influence.

In the meantime, Gladstone (*C. J.* 45, 241) had brought together a large number of observations on organic compounds, both liquids and solutions of solids, and placed against them the refraction-equivalents calculated on the basis of the following values for the elements:—

Carbon, saturated . . .	R_A 5·0
„ in C_nH_n	5·95
„ doubly linked . . .	6·1
Hydrogen	1·3
Oxygen, singly linked . . .	2·8
„ doubly „ . . .	3·4
Nitrogen	4·1
„ in bases, NO_2, &c. . .	5·1
Chlorine	9·9
Bromine.	15·3
Iodine	24·5
Sulphur, singly linked . . .	14·1
„ doubly linked . . .	16·0

Gladstone's observations confirm Landolt's original determination for H, and also for C in saturated compounds. Gladstone points out that the hydrocarbons of the formula C_nH_n scarcely come up to Brühl's previous estimate of the higher value of C, so that in these cases he has adopted the figure 5·95 instead of 6·1, as the difference is more than he considers can be accounted for either by dispersion or by the distance from the boiling-points. In the case of those substances where the C atoms outnumber those of H, all of which show an inordinately high refraction and are at the same time enormously dispersive, Gladstone points out that Kanonnikoff's view that the increase is due to dispersion alone is not established by that observer's own figures for the theoretical limit of the spectrum according to Cauchy's formula. He admits, however, that if the limit were carried back considerably further, though still fairly within what Langley's observations would allow, the values would so far approximate as to render it not impossible that the refraction-equivalent of C might prove to be the same in these compounds as in the benzenoid series, or wherever it is doubly linked. As to the halogens, the figures in the table are generally consistent with the values which were originally assigned by him to Cl, Br, and I, viz. 9·9, 15·3, and 24·5 respectively. These numbers are very nearly the same as those arrived at independently by Haagen, viz. 9·8, 15·3, and 24·8. The values for O are taken from Brühl's original determinations, though the evidence of the alcohols rather favours his old estimate of 2·9 for the line A.

With regard to the phenomena of dispersion, Gladstone points out 'that the double linking of carbon atoms, while it does not much affect the specific refraction, widens the spectrum greatly, to such an extent indeed that where there are three pairs of such carbon atoms the specific dispersion is about double that of a saturated compound; where, however, the carbon atoms are actually in excess the dispersion becomes far more rapid. This is evident throughout, but the following typical hydrocarbons may illustrate it:—

Hexane .	C_6H_{14}	sp. ref.	0·5626,	sp. disp.	0·0242
Amylene .	C_5H_{10}	„	0·5708	„	0·0300
Benzene .	C_6H_6	„	0·5595	„	0·0486
Napthalene	$C_{10}H_8$	„	0·5870	„	0·0782
Difluorene	$C_{26}H_{18}$	„	0·6057	„	0·1108

or the following alcohols:—

Isobutyl alcohol	$C_4H_{10}O$	sp. ref.	0·4878,	sp. disp.	0·0209
Allyl alcohol	C_3H_6O	„	0·4731	„	0·0275
Phenol	C_6H_6O	„	0·5090	„	0·0476
Naphthol	$C_{10}H_8O$	„	0·5487	„	0·0832

'The effect of the halogens in lowering both the specific refraction and dispersion is very marked, and that of NO_2 is still more remarkable.'

Gladstone (*C. J.* 59, 290, 589) has since published other long series of observations; including a record of experiments on the effect of changes of temperature on the refraction of some highly-refractive substances, which seem to confirm the opinion previously expressed by Dale and himself. Among the substances contained in these tables the benzyl and benzal camphors of Haller call for special notice, as they have a very high refraction, and a dispersion which is altogether excessive. The latter compound has in like manner a very high rotatory power. The hydracids in aqueous solution are shown to have not only a higher value than the normal, a fact which has long been observed, but also that the value rises with dilution; and that in the dispersion the excess is still more striking. The same fact was observed by Perkin in regard to the molecular magnetic rotation of these acids dissolved in water, both as to the initial excess, and to its increase with the dilution up to a certain point where it remained nearly constant.

Other investigators have availed themselves of the optical properties in order to determine the constitution of compound bodies, or to confirm the views arrived at on other grounds. Knops (A. 248, 175) has determined the indices of refraction of the methyl, ethyl, and propyl salts of fumaric, maleic, mesaconic, citraconic and itaconic acids. A comparison of these acids with their ethereal salts leads to the conclusion that fumaric and maleic acids contain only one doubly-linked carbon atom; and that fumaric acid stands in the same relation to maleic acid as mesaconic acid does to citraconic acid.

Kanonnikoff (*J. pr.* [2] 31, 321, 497) has made a long series of observations on solutions of solids, of which he tabulates seventy-nine different substances, using water, alcohol, benzene, and chloroform as the solvents. As a preliminary inquiry, he reviewed the work of former investigators, and in some cases added experiments of his own to confirm previous conclusions: that the refractive energy of a substance is not changed in passing from the state of a liquid to that of a gas or vapour; that the same applies to bodies in passing from the solid to the liquid condition; that the refraction-equivalent of a mixture of liquids is the sum of the refraction-equivalents of its constituents; and that if the refraction-equivalent of a mixture and that of one of the components, together with the proportion of the same, is known, the refraction-equivalent of the other component can be calculated; that the same law applies to solutions of solid bodies, and that like results will be obtained whatever the solvent may be; that a derivative will be comparable with the substance from which it is derived, though the one may be a liquid and the other a solid body, as in the case of mesaconic acid and ethyl mesaconate. From the results of the observations above referred to, K. has determined the refraction-equivalents of fourteen of the elements, as follows:—

Element	R_C	R_∞	Element	R_C	R_∞
Lithium . .	3·16	3·00	Magnesium .	7·03	6·47
Sodium . .	4·22	4·00	Calcium .	9·32	9·05
Potassium .	7·75	7·40	Zinc . .	9 80	9·40
Copper . .	—	11·30	Strontium .	11·61	11·25
Rubidium .	12·04	11·60	Cadmium .	13·03	12·66
Silver . .	13·05	12·53	Barium .	15·84	15·28
Cæsium . .	19·55	18·70	Mercury .	19·20	17·90

K.'s values for the solar line C will be found to be generally slightly lower than those determined by Gladstone for the line A. The refraction-equivalents for the theoretical limit of the spectrum were also calculated by Cauchy's formula from observations of the lines α and β of hydrogen. K. also gave determinations of refraction-equivalents of thirty organic liquids, showing the excess due to the double linking of the carbon atoms wherever this occurred.

Nasini (*Lincei*, *Rc.* 1, 1) points out that the suggestion thrown out by Gladstone that there may be a third and higher value of carbon when its four bonds are satisfied by other carbon atoms, is supported qualitatively by the researches of Bernheimer and himself, but not quantitatively, and that, therefore, this hypothesis is not a sufficient explanation of the facts. He argues as follows: naphthalene derivatives have two such atoms, while cinnamic alcohol has but one, whereas the values differ but very little. Anethol with one such carbon atom has a much greater excess than the naphthalene derivatives, while styrol shows so slight an excess, that on this hypothesis it could hardly be allowed to have any carbon atom in this condition. He compares two pairs of isomeric bodies, both as to refraction and dispersion,

Substance	R_α	$\frac{\mu_\beta - \mu_\alpha}{d}$
Allyl phenylate . .	70·45	0·0173
Cinnamic alcohol .	73·83	0·0220
Allyl paracresolate .	78·79	0·018
Anethol . . .	82·95	0·0257

from which he infers that when the allyl group is directly united to the benzene nucleus the molecular refraction greatly increases, whereas when the union takes place through the intervention of oxygen no augmentation takes place; so far, therefore, while supporting the hypothesis of Gladstone, he does not find any proportionality between the number of such carbon atoms and the increase of refraction.

Nasini (*Lincei*, *Rc.* 3, 164) criticises some of the conclusions of Brühl in the paper on the molecular refraction of organic liquids of high dispersive power (*A.* 235, 1) already referred to; and in particular he points out that the elimination of dispersion, if that were possible, would not get rid of the discrepancies between the observed and calculated values for the refraction of substances of high refractive power, and he cites observations on a series of substances in which he finds the constant fact that on adding a saturated side chain to an aromatic nucleus the specific dispersion diminishes while the refractive power increases.

Costa (*G.* 19) has made observations with the special object of testing the effect on dispersion of adding saturated side chains to a benzene or naphthalene nucleus. For this purpose he used compounds of amyl with benzene, thymol, eugenol, resorcin, and naphthol, and found in each case a still further increase in the refraction-equivalent than could be accounted for by the nucleus itself, while at the same time the specific dispersion showed a decrease.

Dispersion equivalents. In the same way that Gladstone arrived at the refraction-equivalents of the elements, he has sought also to determine the dispersion-equivalents of several of them; and (*Pr.* 42, 401) he has given the results of his observations upon nine of them, together with the values for the combinations CH_2 and NO_2. The values are as follows:—

Substance	R_A	Disp. Eqt. H–A
Phosphorus . .	18·3	3·0
Sulphur, doubly linked	16·0	2·6
„ singly „	14·0	1·2
Hydrogen . . .	1·3	0·04
Carbon . . .	5·0	0·26
„ . . .	6·1?	0·51
„ . . .	6·1	0·66
Oxygen, doubly linked	3·4	0·18
„ singly „	2·8	0·10
Chlorine . . .	9·9	0·50
Bromine . . .	15·3	1·22
Iodine . . .	24·5	3·65
Nitrogen . . .	4·1	0·10
CH_2	7·6	0·34
NO_2	11·8	0·82

It will be observed that G. gives three dispersion equivalents for C, which he considers pretty well established, and he raises the question whether there may not be an intermediate refraction-equivalent corresponding to the dispersion-equivalent 0·51, which is found in such bodies as the allyl compounds and olefines. In his previous paper (*Pr.* 31, 327), G. suggested that there is a still higher refraction-equivalent of C in those cases in which it has four bonds satisfied by other C atoms, as in naphthalene and pyrene. Whatever may be the truth of this view, it appears that the dispersion-equivalents of these bodies are enormously high — much beyond what is recognised in the above table.

Brühl (*Z. P. C.* 7, 2, 140) has since modified his views upon the subject of dispersion; and has worked out carefully the atomic dispersions of some of the most important elements that enter into organic compounds. In the course of this investigation he has been led to revise his previous figures for the refraction as well as the dispersion. They now stand as follows:—

	Symbol	R_a	$R_\gamma - R_a$
Carbon, singly linked .	C'	2·365	0·039
Hydrogen . . .	H	1·103	0·036
Oxygen (hydroxyl) .	O'	1·506	0·019
„ (ether) . .	$O\!<$	1·655	0·012
„ (carbonyl) .	O''	2·328	0·086
Nitrogen, linked singly with C . . .	N'	2·76	0·19
Chlorine . . .	Cl	6·014	0·176
Bromine . . .	Br	8·863	0·348
Iodine	I	13·808	0·774
Ethylene bond . .	=	1·836	0·23
Acetylene bond . .	≡	2·22	0·19

It will be observed that B. retains Lorenz's formula; and that he takes the difference between the refraction of the hydrogen lines γ and a as his measure of dispersion. He now acknowledges that the molecular dispersion can be regarded and employed in like manner with the molecular refraction as a specific expression of the material composition of chemical bodies; and that the dispersion is decidedly more sensitive to structural influences than the refraction. His inquiries have convinced him that refraction and dispersion are in no general sense correlative properties; but that certain structural peculiarities that have much influence upon refraction have little upon dispersion, while others have the opposite effect, and, as a rule, exercise a much stronger influence upon the dispersion. It is evident that this must be so, from the very high relative dispersion of O'' as compared with that of O' or $O\!<$, and the large proportionate dispersion due to the ethylene bond. This figure, ·23, B. does not, however, recognise as a constant value. These revised values have since been used by him in his inquiries into the relations between the optical properties and chemical constitution of epichlorhydrin, the aldehydes and benzoyl (*B. B.* 24, 656), in which he draws attention to the concurrence of the evidence derived from chemical, calorimetrical, and optical investigations.

Essential oils. Gladstone (*C. J.* 17, 1; 25, 1) gave a long list of observations in which he recorded the circular polarisation as well as the index of refraction. The power of the oils in rotating the plane of polarisation appears to be very diverse, both in degree and direction; but he suggests that a comparison of the specific gravity and of the length of the spectrum may in some cases be of service in determining the genuineness or otherwise of the oils. The hydrocarbons obtained from these oils (of which a long table is given) divide themselves into two great groups, which are more fully investigated in the second paper.

Subsequently (*C. J.* 49, 609) the effect of the higher refraction and dispersion of C when united by double bonds was applied to the determination of the structure of the essential oils. Taking 2·2 as the increased refraction for the solar line A, and 0·8 as the increased dispersion, H—A, due to one pair of doubly-linked carbon atoms, the terpenes indicate, both by their refraction and dispersion, that they contain only one pair of carbon atoms doubly linked, thus corroborating the views of those who, on chemical grounds, have held that a terpene requires the addition of only two atoms of hydrogen, or their equivalent, to saturate it. The refraction and dispersion of solid inactive camphene also show that this substance does not contain more than one pair of doubly-linked carbon atoms, which is consistent with the fact that it combines with only one molecule of hydrochloric acid, and is directly converted by oxidation into camphor $C_{10}H_{16}O$, which is certainly a saturated compound both by chemical and optical evidence. In the same way, the citrenes give a refraction and dispersion indicative of the presence of two pairs of doubly-linked carbon atoms. Allied to these are several hydrocarbons having different amounts of hydrogen, and the number of doubly-linked carbon atoms varying accordingly. Thus, while citrene $C_{10}H_{16}$ has two pairs, cymene $C_{10}H_{14}$ has three, while menthene $C_{10}H_{18}$ has but one pair of doubly-linked carbon atoms, and cymhydrene $C_{10}H_{20}$ has none, being a saturated body. Pentene and isoprene C_5H_8 are identical in their optical properties, and indicate that no less than four of the five carbon atoms are doubly linked, which accords with the fact that these compounds combine with four atoms of bromine or two molecules of hydrochloric acid. The following table will illustrate the foregoing conclusions :—

Hydrocarbons	Experimental		Pairs of C atoms doubly linked	Theoretical	
	Specific refractive energy	Specific dispersive energy		Specific refractive energy	Specific dispersive energy
Cymhydrene . . .	0·543	0·0246	none	0·543	0·0243
Menthene	0·548	0·0313	one	0·547	0·0298
The terpenes . . .	0·537	0·0295	do.	0·537	0·0296
Terebenthene . . .	0·537	0·0294	do.	,,	,,
Camphene	0·528	0·0269	do.	,,	,,
The cedrenes . . .	0·538	0·0296	do.	,,	,,
The citrenes . . .	0·551	0·0334	two	0·553	0·0354
Isoterebenthene . . .	0·552	0·0337	do.	,,	,,
Caoutchene . . .	0·554	0·0366	do.	,,	,,
Cymene	0·560	0·0406	three	0·558	0·0413
Isoprene	0·592	0·0470	four	0·585	0·0472

The advance in these experimental figures with the double linking is evident, though it is obscured in the first two cases by the larger amount of hydrogen contained in cymhydrene and menthene. The influence of the double linking upon the specific dispersive energy is apparent at a glance, and renders this property more valuable than the refractive energy in determining the rational constitution; though, of course, it is in the agreement of the two that the most conclusive evidence must be sought.

Kanonnikoff (*Bl.* [2] 36, 557) had already pointed out the differences between the calculated and observed refraction equivalents for the following substances :—

Substance	R_∞	Calculated	Difference
Peppermint camphor .	77·6	77·1	+ 0·5
Cajeputene hydrate .	74·8	74·5	+ 0·3
Terebenthene hydrate, lævogyrate . .	77·1	74·5	+ 2·6
French terebenthene, lævogyrate .	71·7	69·2	+ 2·5
Hydrocarbon from *oleum camillæ* . .	71·9	69·2	+ 2·7
Hydrocarbon from *oleum thymiani* .	71·4	69·2	+ 2·2
Isoterebenthene . .	73·6	69·2	+ 4·4
Carvol	74·8	69·4	+ 5·4
Cymene from camphor .	72·0	66·6	+ 5·4

K. has drawn the conclusion that the first two contain no double bond, that the two terebenthenes and the two hydrocarbons contain one double bond, that isoterebenthene contains two, and that carvol and cymene contain three, double bonds.

Carbon. Schrauf (*W.* 22, 424) made observations on the refraction of a Brazilian diamond of the first water, the S.G. of which was 3·516, with the following results :—

μ_{Li} 2·408449
μ_{Na} 2·417024 and 2·417227
μ_{Tl} 2·425487

These figures give $R = 4·8$, a result slightly lower than his earlier observations on the diamond, in which the index for the red part of the spectrum is recorded as 2·434, and the S.G. 3·55.

Selenion. Sirks (*P.* 143, 429) made observations on the refraction and dispersion of solid Se. By pressing a small quantity of melted Se between two glass plates, he prepared a thin film of the substance, which exhibited Newton's interference bands. From these he was able to calculate the index of refraction for the solar lines A, *a*, B and C, with an estimated error not exceeding 0·003; and for D, with some difficulty and uncertainty, to the second place of decimals only. The values obtained were:—μ_A 2·654, μ_a 2·692, μ_B 2·730, μ_C 2·787, μ_D 2·98. From these S. calculated the dispersion as compared with water, calcspar, and CS_2, the figures in each case being reduced to the standard of $\mu_C - \mu_A = 100$:—

	$\mu_a - \mu_A$	$\mu_B - \mu_a$	$\mu_C - \mu_B$	$\mu_D - \mu_C$
Water . .	36	31	33	88
Calcspar . .	36	30	34	90
Disulphide of carbon . .	34	31	35	99
Selenion . .	29	30	42	146

Comparing Se with CS_2, he found that while in the case of CS_2 $\mu_D - \mu_C$ differed very slightly from $\mu_C - \mu_A$, in the case of Se $\frac{\mu_D - \mu_C}{\mu_C - \mu_A} = 1·46$.

In testing Cauchy's and Christofle's formulæ for the index of the ray of infinite wave-length by the above observations, the former gave 2·733 and the latter 2·433. It will be observed that Cauchy's co-efficient of refraction is somewhat higher than the observed value for the solar line B, which is 2·730, the co-efficient of dispersion in this particular case being a minus quantity.

Phosphorus. Gladstone and Dale (*P. M.* 1859) measured the index of refraction of both solid and liquid P, an element remarkable not only for its very high refractive power, but for an unprecedented amount of dispersion. For solid P at 25° they obtained for μ_A 2·1059, for μ_B 2·1442, and for the extreme limit visible in the violet portion of the spectrum 2·3097. Assuming the latter to be equivalent to μ_H, the length of the spectrum $\mu_H - \mu_A = 0·2038$. For liquid P at 35° they obtained the following:—

μ_A	μ_D	μ_F	μ_G	End of violet
2·0389	2·0746	2·1201	2·1710	2·2267

The change from the solid to the liquid state is attended with a considerable diminution of density, the ratio between the density and the refraction being about the same in the two conditions. The R_A of P is taken at 18·3 from the above observations on liquid P, but Gladstone points out (*C. J.* 23, 101) that when combined with O it seems to have a much smaller refraction, HPO_3 giving a less value (18·0) than the P it contains, while H_3PO_4 also has a refraction-equivalent of only 23·6.

Sulphur. It was pointed out by Gladstone in 1869 (*T.* 159, 9) that while S, whether solid or liquid, has a refraction-equivalent of 16·0 or 16·3 for the solar line A, the equivalent for S deduced from CS_2 was 15·85; that the difference between KCN and KCNS gave a value of 16·24, and that S_2Cl_2 gave a similar figure. On the other hand, however, it was evident that in the two gases $H_2S = 14·28$, and $SO_2 = 14·91$, or in liquefied $SO_2 = 14·59$, the refraction-equivalent of S cannot amount to 16·0, nor yet in H_2SO_4, which has a refraction-equivalent of only 21·9.

Wiedemann and Nasini have subsequently given considerable attention to the values of S in combination. Wiedemann (*W.* 17, 577) investigated the sulphur substitution products of the carbonic esters, and obtained the following results:—

		d	μ_{Li}	μ_{Na}	μ	R_∞	$\mathbf{R}_\infty$
I.	$CO\genfrac{}{}{0pt}{}{OC_2H_5}{OC_2H_5}$	0·975	1·3837	1·3858	1·3876	45·66	27·80
II.	$CO\genfrac{}{}{0pt}{}{OC_2H_5}{SC_2H_5}$	1·0285	1·4479	1·4515	1·4544	56·95	34·11
III.	$CO\genfrac{}{}{0pt}{}{SC_2H_5}{SC_2H_5}$	1·085	1·5168	1·5237	1·5287	69·15	40·57
IV.	$CS\genfrac{}{}{0pt}{}{OC_2H_5}{OC_2H_5}$	1·0325 ?	1·4563	1·4601	1·4632	57·82	34·56
V.	$CS\genfrac{}{}{0pt}{}{OC_2H_5}{SC_2H_5}$	1·085	1·5301	1·5370	1·5431	70·26	41·23
VI.	$CS\genfrac{}{}{0pt}{}{SC_2H_5}{SC_2H_5}$	1·152	1·6105	1·6210	—	82·73	47·56

From these figures it will be seen (1) that the index of refraction rises whenever an atom of O is replaced by an atom of S, and that so much the more, the more S there is already in the compound; (2) that the refractive indices of the combinations which contain the radicle CS are greater than those of their analogues containing CO; (3) that the refractive index likewise increases if, besides the radicle, first one and then a second atom of S replaces O, and in the latter case more than in the former; (4) the isomeric bodies II. and IV., as well as III. and V., have quite different indices of refraction, and in both cases the compound that has the S in the radicle has the higher index. This indicates that the position of the S in the compound influences, in a very distinct manner, the value of the index of refraction. From the refraction-equivalents given above W. obtains the value 14·04 for S′ in the compounds II. and III.; and for S″ 15·20, 16·31, and 17·45 respectively. Using Lorenz's formula he gets the value of 7·94 for S′, and 9·09, 9·44, and 9·88 for S″. Whichever formula be adopted, the figures show that the atomic refraction of S, like that of O, is greater when S is doubly linked to an atom of carbon. It should be observed that the above results are based upon the recognised values of C, H, O′, and O″, which give

$$CO\genfrac{}{}{0pt}{}{OC_2H_5}{OC_2H_5} = R_\infty\ 45·91, \text{ and } \mathbf{R}_\infty\ 27·76;$$

and also that W. takes as the value of S′ the mean derived from the observations II. and III. If Wiedemann had adopted a direct comparison of the actual observations, the values of S″ would approximate more closely according to the old formula, and less closely according to Lorenz's formula.

Nasini (*G.* 13, 296; *Lincei, Rc.* 1, 1) has determined the value for S in various compounds. From sundry organic sulphides and mercaptans he obtained the atomic refraction of S corresponding to alcoholic oxygen. From CS_2, and from the compound $CS(OC_2H_5)_2$, he deduced the refraction of S corresponding to aldehydic oxygen:—

Sulphur	R_a	R_∞	$\mathbf{R}_a$	$\mathbf{R}_\infty$
S′ (singly linked) .	14·10	13·53	7·87	7·65
S″ (doubly linked) .	16·05	15·09	9·02	8·84

But when examining other compounds, such as H_2SO_4, SO_3, and SO_2, N. found that whatever hypothesis he adopted as to their constitution—or, in other terms, whatever value he took for the atomic refraction of O—he obtained values for S, not very discordant among themselves, but totally different from those given above. Treating the sulphur as divalent, R_∞ varied from 8·10 to 9·01; as tetravalent, from 6·94 to 8·43; as hexavalent, from 6·63 to 7·85. Calculating by Lorenz's formula, $\mathbf{R}_\infty$ ranged from 5·24 to 6·27 in the first case, from 4·51 to 4·91 in the second, and from 3·13 to 3·79 in the third. Some observations recorded by Kanonnikoff (*J. R.* 15, 434) substantially support these figures.

Nasini and Scala (*Lincei, Rc.* 1886. 617, 623) record observations on the sulphocyanides, which show that the mustard-oil compounds have refractive and dispersive powers in excess of those of their isomerides, while phenylic isosulphocyanide has a specific refraction and dispersion far above the calculated values—exceeding, in fact, oil of cassia or CS_2. In this combination the union of the group S=C=N, endowed with a high refractive power, with the phenylic group, also highly refractive, appears to produce a heightening of the refrangibility, a phenomenon which N. regards as analogous to the increase in refraction which he observed when in the benzene group an unsaturated side chain is joined to an unsaturated carbon atom. In compounds containing four atoms of S there is an excess of refraction above what is estimated from the value of S in CS_2, the monothiocarbonates of Et and Pr giving a value of 17·4 and 17·5 for the refraction-equivalent of sulphur.

Nasini a. Costa (*Ist. Ch. Rome*, 1891) made further studies of S and its compounds. They conclude that the oxygen compounds, which are generally distinguished by a low refractive and dispersive power as compared with those not oxygenated, may be divided into two principal groups: those which may be regarded as derived from SO_2 have the higher, and those derived from SO_3 have the lower, refractive and dispersive powers. Kanonnikoff (*S. Ph. Ch. Russ.* 16, 129) assumed that the refraction of S varies with the change of valency, and assigned the following values for R_a:—

S divalent 14·10
S tetravalent 8·72 (in sulphones)
S hexavalent 4·85 (in H_2SO_4)

but this is not accepted by N. and C. They find that the accumulation of S in the molecule is almost always accompanied by an increase in the refractive and dispersive power. In this respect, though not in others, S appears to have much analogy with carbon. Throughout this investigation N. and C. tested the dispersion formula of Ketteler, $\frac{\mu_a^2-1}{\mu_b^2-1}$, in which *a* and *b* represent rays of different wave-length, and found that it gave very uniform results; but from a physico-chemical point of view they do not regard this fact as an argument in favour of the formula.

Sulphuric acid. Van der Willigen published (*Ar. N.* 8) a long series of very careful determinations of the indices of refraction of mixtures of H_2SO_4 and H_2O, in various proportions for all the principal lines of the solar spectrum from A to H inclusive. These show a progressive increase in refraction and dispersion with every addition of H_2SO_4, until a maximum is reached at a point corresponding, apparently, with the monohydrate of the acid, after passing which the refraction and dispersion suddenly decline, while the density of the mixture continues to increase. Out of the seventeen series of determinations at different concentrations, the seven most conc. are given below, the central one of the series representing the nearest approach to the maximum. The indices are all reduced to a temperature of 18·3°. The specific gravity given in the line below is for 0°, water at the same temperature being taken as 1·0. In the cases of the two G's and the two H's, the higher one in each corresponds with the lines so designated by Fraunhofer.

Van der Willigen pointed out that the formula $(100-p)\frac{n^2-1}{d}+p\frac{n'^2-1}{d'}=100\frac{n''^2-1}{d''}$ will not apply to mixtures of H_2SO_4 and water, where $100-p$ and p are the respective weights of the two mixed liquids, *n*, *n'*, and *n''* the indices of refraction, and *d*, *d'*, *d''* the densities of the two liquids and the mixture respectively. Dale and Gladstone had formerly stated that the same was the case in respect of their formula.

Nickel and iron carbonyls. Ludwig Mond has prepared $Ni(CO)_4$ and $Fe(CO)_5$, both liquids of a highly-refractive character. The former has been examined optically by Nasini (*Lincei, Rc.* 7, 411), and the latter by Gladstone. R_a for the nickel compound was found to be as high as 57·7, which, deducting 8·4 for the value of each CO, gives $R_a = 24·1$ for the metal itself, instead of about 10·0, as determined from the chloride, sulphate, and nitrate. This would seem to confirm the hypothesis that the refractive power varies with change of valency, increasing with the increased power of combination. In this compound the Ni is regarded by Mond a. Nasini as octovalent, and as justifying Mendeléeff in placing it in Group VIII. of his system of classification. Gladstone, on the other hand, is disposed to think that the metal in both compounds is, as usual, divalent, and that it is the

CO which has a greatly increased value. He obtained for $Fe(CO)_5$, $R_A = 67\cdot38$, $R_D = 69\cdot40$. These figures show not only a very high refraction, but also very great dispersive power.

Silver iodide, bromide, and chloride. Wernicke (*A.* 142, 560) measured the refraction and dispersion of light by these salts in two different ways: (1) by examining the light reflected from glass plates covered with a layer of these salts, by means of a spectroscope, and noting the position of the dark interference-bands; (2) by direct measurements of small prisms made of the fused salts. The portion of the spectrum observed ranged from the solar line C to G. The dispersion $\mu_G - \mu_D$ was about twenty-seven times that of water in the case of the iodide; that of the other two salts is much less, though considerably greater than that of flint glass. AgI seems capable of existing in two conditions: at temperatures above 138° it gives a short spectrum limited to the red, yellow, and green, while below that temperature it gives a spectrum twice as long, showing all the colours. W. believes that AgI is partly dissociated at the higher temperatures.

Bromine. Weegmann (*Diss.* Bonn, 1888) determined the refraction-equivalent of Br by Lorenz's, as well as by the older, formula, for both the hydrogen lines, α, and Cauchy's limit, from a series of ethylene and acetylene compounds, adopting Brühl's values for C, H, and the ethylene linking. The following are his figures for Br compared with those arrived at by Brühl:—

Bromine	R_∞	R_a	R_∞	R_a
Weegmann .	14·78	15·38	8·56	8·83
Brühl . .	14·81	15·39	8·70	8·95

Fluorine. The writer of this article has collated the observations made by various observers on bodies containing F in order to arrive at the refraction-equivalent of this element (*P. M.* 1885. 481). Those of Brewster on cryolite, of Brewster, Wollaston, Fizeau, Stefan, and Kohlrausch on fluorspar, and of Gladstone on aqueous solutions of KF, give a refraction-equivalent for F varying from 0·29 to 0·32. Those of Topsöe and Christiansen on crystalline silicofluorides of Cu, Ni, Zn, Mg, and Mn, of the formula $RSiF_6.6H_2O$, give a refraction-equivalent for F varying from 0·62 to 0·84; while $(NH_4)_2SiF_6$ gives 0·59 for F. The latter figures must be accepted with caution, as a very slight difference in the values ascribed to the other elements will account for the whole of the discrepancy. It is evident, however, that in any case the refraction-equivalent is of exceedingly small amount, and that the specific refraction, even if the highest value be taken, can scarcely be the half of that of any other element known.

J. H. and G. Gladstone (*P. M.* 1891. 1) have investigated the optical properties of fluorbenzene and allied compounds. The molecular refraction for C_6H_5F, for six lines of the solar spectrum, is given in the following table; from this is deducted the value for benzene less one atom of H, leaving a small balance as the atomic refraction of fluorine.

These figures are remarkable as giving a negative value for the dispersion $R_H - R_A$, namely the quantity, −0·28. According to Lorenz's formula $R'_A = 0\cdot92$ and $R'_H = 0\cdot84$, showing in like manner a negative dispersion. The observations of Baille, Stefan, and Sarasin on fluorspar, and those of the authors on solutions of KF and NH_4F, all distinctly confirm the foregoing evidence as to the anomalous dispersion; while a comparison of the refraction of the three lines C, D, and F of the solid silicofluorides measured by Topsöe and Christiansen, and the author's observations on aqueous solutions of H_2SiF_6, seem to point in the same direction.

	R_A	R_C	R_D	R_F	R_G	R_H
C_6H_5F	42·92	43·33	43·70	44·68	45·61	46·40
C_6H_5	42·29	42·70	43·17	44·20	45·17	46·05
F	0·63	0·63	0·53	0·48	0·44	0·35

Liquefied gases. Bleekrode (*Pr.* 37, 339) adopted a special apparatus for measuring the indices of refraction of liquefied gases, consisting of a modification of a Faraday tube, forming a vessel having two parallel side plates, free from leakage even at high pressures. By observing, through a microscope provided with a graduated scale and a micrometer screw, test objects, such as lepidoptera scales, attached to the inner surface of the glass plates of the cell, the variation in the focus between the direct observation and that through the cell and liquid was found, and, with a correction for the effect of the glass, he obtained the data from which to calculate the index of refraction according to the equation $\frac{D}{D-d} = \mu$, in which D represents the thickness of the layer of liquid and *d* the apparent displacement of the test object. The observations were taken both with a sodium flame and with daylight, and the calculated probable error of the result amounted to ± 0·003. The first table on p. 238 gives the results of B.'s observations compared with those of Dulong, Ketteler, Croullebois, and Lorenz on the same substances in the gaseous state; the specific refraction is calculated by both the formulæ in common use.

B. drew attention to the remarkably low S.G. of ethylene, as the lightest fluid substance known; his determinations gave 0·335 at -8°, 0·361 at 6°, and 0·386 at 3°. B. also gave determinations of the indices of refraction of the following substances taken by the same process; and commented on the high indices of the organo-metallic compounds as inconsistent with the opinion expressed by early observers that a high index of refraction is indicative of a body being combustible.

Substance	Temp.	μ_D
Hydrobromic acid . .	10°	1·325
Do. . .	15°	1·330
Hydriodic acid . . .	16·5°	1·466

Liveing and Dewar (*P. M.* 1892. 205) have determined the refractions of three liquefied gases, at their respective boiling-points, by direct observation through a hollow prism. They obtained the following results for the sodium line D:—

	μ_D	R_D	R_D
Oxygen	1·2236	3·182	2·024
Nitrous oxide	1·3345	11·587	7·163
Ethylene	1·3632	17·556	10·752

Alums. The indices of refraction of some of the alums have been measured by several observers, amongst them Grailich, Fock, Kohlrausch, Stefan, Topsöe, and Christiansen. The most complete series of observations on inorganic sulphuric alums is that of Soret (*Ar. Sc. Genève*, 12, 553; 14, 96; 20, 517), including those containing Rb, Cs, In and Ga. His mode of determination was by total reflection, which he considered the best adapted for the purpose; he gave indices which he calculated to be correct to two units in the fourth place of decimals. His observations were given for eight rays of the solar spectrum, viz. the lines *a*, B, C, D, E, *b*, F, and G. He remarked on the very low value of the index of refraction of the Na—Al alum. He gave the following comparative table for μ_D, showing that the different series of alums vary in general with much regularity. The horizontal lines contain the same metal, and the vertical lines the same metal or alkaline radicle.

	NH_4	K	Rb	Cs	Tl
Aluminium	1·4594	1·4564	1·4566	1·4586	1·4975
Indium	1·4664	—	1·4638	1·4652	—
Gallium	1·4683	1·4653	1·4658	1·4649	1·5066
Chromium	1·4842	1·4814	1·4815	1·4810	1·5228
Iron	1·4848	1·4817	1·4823	1·4838	1·5236

Calculating for each salt the difference between its μ_D and that of the ammoniacal alum on the same horizontal line, Soret obtained:—

	NH_4–K.	NH_4–Rb	NH_4–Cs	NH_4–Tl
Aluminium	+0·0030	+0·0028	+0·0008	−0·0381
Indium	—	0·0026	0·0012	—
Gallium	0·0030	0·0025	0·0034	0·0383
Chromium	0·0028	0·0027	0·0032	0·0386
Iron	0·0031	0·0025	0·0010	0·0388

These figures show a close accord, except in the case of Cs, in which the Ga and Cr compounds appear to be too low. Soret did not consider that the impurity in the specimens, if any existed, could be due to the Cs.

Gladstone (*P. M.* 1885. 162) worked out the refraction-equivalents from the data given in the first named of Soret's papers, and also from those by Topsöe and Christiansen, in order to test his former conclusions that a salt has the same specific refraction whether it is in a solid form or in solution, and that the refraction-equivalent of a compound body is the sum of the refraction-equivalents of its constituents. As to the first point, in the case of the two alums given below he found the specific refractions, after deducting the amount due to the solvent, to be in substantial accord:—

	Dissolved	Crystallised
Ammonium-aluminium alum	0·2780	0·2784
Sodium-aluminium alum	0·2613	0·2604

To test the second point, the alums were regarded as compounds of the sulphates of two metals of different kinds with twenty-four molecules of water. Taking the R_A of water in the uncombined state at 5·926—and taking the observations of Kanonnikoff, Topsöe, and Christiansen, as well as his own, of the several sulphates—Gladstone arrived at the results given in the following table. The other observers did not take the A line, but their observations have been reduced to A for purposes of comparison. The agreement between the calculated and observed refraction-equivalents is as near as might be expected, except in the case of Cs.

Substance	R_A calculated	R_A observed and reduced	
		Soret	Topsöe and Christiansen
Ammonium-aluminium alum	252·0	252·2	—
Sodium " "	239·3	238·5	—
Methylamine " "	267·2	267·7	—
Potassium " "	245·1	246·8	—
Rubidium " "	254·0	253·7	—
Caesium " "	268·0	262·3	—
Ammonium-chromium alum	264·0	265·9	—
Potassium " "	257·1	261·2	—
Rubidium " "	266·0	266·7	—
Caesium " "	280·0	275·5	—
Ammonium-iron alum	270·6	269·1	268·6
Potassium " "	263·7	265·0	261·4
Rubidium " "	272·6	273·2	—
Caesium " "	286·6	276·0	—

Gladstone also sought, by means of Soret's observations, to determine the refraction-equivalents of In and Ga, and (*B. A.* 1892) he gave the following constants:—

	At. W.	R_A
Indium . . .	113·4	13·7
Gallium . . .	69·9	11·6

These figures, however, can only be looked upon as approximate, as all experimental errors are accumulated on these residual numbers.

Perrot (*Ar. Sc. Genève*, 1880) has made a series of observations on the refraction and dispersion of an isomorphous series of biaxial crystals—the double sulphates of Zn with K_2, Rb_2, $(NH_4)_2$, Cs_2, K_2, and of Mg with Rb_2, and in each case $6H_2O$. He has followed the plan adopted by Soret in his observations on the alums. The results conform satisfactorily to the values computed on the same principle as that adopted by Gladstone with respect to the alums, except in the case of cæsium and rubidium, in both of which, especially the former, the observed values are lower than the theoretical. The mean ray adopted for this calculation is, however, the arithmetical mean of the three indices observed for each of the lines of the spectrum, and has, therefore, no real physical significance. A glance at the tables of observations will show at once what a wide scope for error there is in arriving at a mean value by this process.

Analogy between refraction and dispersion and magnetic rotation. Gladstone and Perkin have recently observed an analogy between the magnetic rotation and the refraction and dispersion of light. They have tested this in the case of organic compounds containing nitrogen (*C. J.* 55, 750), with the result that they have found a correspondence that points to some connection between the rotation of the polarised ray under magnetic influence and the retardation of the rays of light in passing through a material substance. These three properties are really comparable with one another, for in each case the observed value is divided by the density of the substance, and it is determined, not for equal weights, but for an equal number of molecules. It has been found that each property is determined in the first instance by the atomic composition of the substance, so that it may be laid down as a primary law that the molecular magnetic rotation, like the molecular refraction or dispersion, of a compound is the sum of the molecular magnetic rotation, refraction, or dispersion of its constituents. The values are, however, subject to large modifications dependent upon differences in the structures of the compounds. Thus a change of valency is attended by a marked change of value in these optical properties, and they are apparently affected by some circumstances which are not as yet recognised in structural formulæ.

The following values have been deduced by Perkin for the molecular magnetic rotations of certain elements in the paraffin group of carbon compounds; and against them are placed the recognised values for their molecular refraction and dispersion:—

	Molecular magnetic rotation	R_A	R_{H-A}
CH_2 . .	1·023	7·6	0·34
C . . .	0·515	5·0	0·26
H . . .	0·254	1·3	0·04
O, alcoholic .	0·194	2·8	0·10
O, aldehydic .	0·261	3·4	0·18
Cl . .	1·733	9·9	0·50
Br . .	3·562	15·3	1·22
I . . .	7·757	24·5	2·62
N, in amines	0·717	5·1	0·38

These figures show a certain analogy; and when modifications are introduced by changes in the mode of combination, the change that occurs in the one property is noticeable also in the other two, and that in the same direction, though not necessarily to the same extent. Thus there are in all cases two different values for oxygen in alcohol and aldehydes, and a very great increase of the values in the case of unsaturated carbon compounds. The values also of CH_2 in the first and second members of homologous series (such as the alcohols, paraffinoid acids, &c.) are different from its value in the higher members of the same series, and always in the same direction.

P. also applied the same inquiry to solutions of HCl, HBr, and HI, which when dissolved in water were known to give higher values for refraction and dispersion than the normal. The same was found to be the case in the magnetic rotations. When HCl was dissolved in isoamyloxide, however, all three values were found closely approximating to the normal, as will be seen in the following table:—

Hydrochloric acid	Molecular magnetic rotation	R_A	R_{H-A}
In water . .	4·412	14·45	1·12
„ isoamyloxide .	2·238	11·36	0·51
By calculation for free acid . .	2·187	11·20	0·54

It is, therefore, laid down as generally, if not always, true, that where there is a departure from the normal values in regard to one or other of these properties, it is to be found in the other two. The different properties are evidently similarly affected by change in chemical constitution. The investigation seems to indicate another close relationship between electro-magnetism and the velocity of light. G. G.

OPTICAL METHODS.—Section 2: SPECTROSCOPIC METHODS.

Historical notes.—Spectrum analysis is an optical method of making a diagnosis of the chemical composition, and in certain cases the chemical constitution, of either (*a*) a self-luminous body, or (*b*) an absorbing medium, whether self-luminous or not. Newton first discovered that light could be analysed when passed through a prism, and, in 1752, Thomas Melvill made an optical analysis of alcohol flames coloured with salt and with nitre. Wollaston, in 1802, observed with the prism certain obscure bands in the solar light which had traversed a narrow slit in his window shutter. Fraunhofer, in 1814–15, was the first to employ a very narrow and accurately-formed aperture with a prism, telescope, and divided circles, and he not only observed the dark lines in the solar spectrum, but measured their indices of refraction or refrangibilities. He examined, subsequently, the spectra of the stars, of electric light, and of the exterior envelope of the flame of a wax candle. The latter spectrum he discovered to consist of homogeneous yellow light, composed of two distinct rays very close together, and coincident with the two dark lines in the solar light which he had termed D. Brewster noted the presence of this yellow light in the combustion of many substances, but it was Fox Talbot who, in 1826, clearly proved that the source of this light was sodium. He likewise connected a red ray with the presence of potassium and an orange ray with strontium, and concluded that *a glance at the prismatic spectrum of a flame may show it to contain substances which it would otherwise require a laborious chemical analysis to detect.* Herschel had previously described the spectra of a few of the metals and of boracic acid. In 1834 Fox Talbot described the strontia and lithia spectra, and stated that optical analysis could distinguish the most minute portions of these two substances with as much, if not greater, certainty than was afforded by any other known method.

Wheatstone, nearly at the same time, published some experiments similar to those of Fox Talbot, and Swan first estimated the amount of sodium which can produce the D lines. At the Manchester meeting of the British Association in 1842, Brewster read a paper *On Luminous Lines in Certain Flames corresponding to the defective Lines in the Sun's Light.* He discovered the dark lines of absorption in nitrogen peroxide gas when white light is directed through it, and he observed and mapped a number of atmospheric lines in the solar spectrum. In 1849 Foucault obtained a reversal of the D lines in the electric arc. Stokes, about 1850, gave in his lectures the true explanation of the coincidence of sodium lines with the dark lines D. Ångström in 1853 stated that an incandescent gas emits luminous rays of the same refrangibility as those which it absorbs, and Balfour Stewart, 1858–9, based the following statement on experimental data: *The radiating power of a body for any ray is equal to its absorbing power for the same ray.*

In 1859, Kirchhoff and Bunsen gave a great impetus to spectrum analysis by publishing their researches on the constitution of the sun, and also by designing an extremely simple spectroscope and describing its use. Chemists were further made aware of the new power placed in their hands by Bunsen's discovery of two new metals, rubidium and cæsium, in 1860, by the discovery of thallium by Crookes and by Lamy in 1862, of indium by Reich and Richter in 1863, and of gallium by Lecocq de Boisbaudran in 1875.

Fundamental laws. Spectrum analysis primarily depends on the following two laws:— 1. Every *solid* and *liquid* when heated begins by emitting rays of longest wave-length, which are the result of comparatively slow vibrations, but as the temperature rises the vibrations become more rapid, and shorter waves are emitted, so that at the highest temperatures the sum of the radiations is white light, consisting of waves of all possible lengths, the effect of which is a continuous spectrum. A mass of iron gradually raised to its melting-point would be an example of this. 2. Every *substance vapourised* by heat emits rays of definite wave-lengths, and these rays are characteristic of each substance, because it alone can emit them. In other words, every substance vapourised by heat has its own definite periods of vibration, by which it can be absolutely identified, because no other substance can vibrate in the same manner and with the same periods. All flame and spark spectra furnish examples. From this second law it follows that the spectrum of an element is a constant of very great importance. The determinations of the spectra and of the atomic weights present similar difficulties, which arise from the necessity for obtaining the elements or their compounds in the highest possible degree of purity, and also in many cases from the complexity of the spectra, and the careful observations which are necessary in identifying and measuring the wave-lengths of the rays.

Determinations of the *absolute wave lengths* of the bright lines in any spectrum are now usually made either with a plane or a concave diffraction grating ruled on speculum metal. When a sufficient number of accurately-measured lines is known for any region of the spectrum, determinations of the wave-lengths of lines in new spectra may be made by observing with a prism-spectroscope, and by the use of an interpolation curve the wave-lengths corresponding to the positions of the lines measured may be found. From time to time the curve will require verifying and correcting.

There are two classes of spectra, *emission* and *absorption* spectra.

Emission spectra consist of: (1) *Continuous spectra* and (2) *Interrupted spectra.* 1. *Continuous spectra* are characteristic of most incandescent solids, liquids, and gases at great pressures, or of a cloud consisting of solid glowing particles. 2. *Interrupted spectra* consist of: (*a*) Bands of light or 'fluted band' spectra, characteristic of certain vapours, especially the vapours of compound substances rendered glowing at comparatively low temperatures; (*b*) bright line spectra, characteristic chiefly of transparent vapours at high temperatures or at low pressures; (*c*) reversed line spectra, which are dark lines seen on a brilliantly-illuminated ground. When a bright line spectrum is observed in front of a more brilliant continuous spectrum, the lines appear dark on a bright ground of colour, instead of bright and coloured on a dark ground, and they are then said to be reversed.

Absorption spectra. When rays capable of giving a continuous spectrum are made to traverse (*a*) transparent solids, (*b*) transparent liquids, (*c*) transparent gases at ordinary temperatures, it is frequently observed that a definite band of rays is absorbed at either end of the spectrum. This is called *a continuous absorption.* Quite as frequently a band of rays is cut out of the middle of the spectrum; this is called a *selective absorption*, and the region of the rays absorbed is said to be occupied by an absorption band.

The production of emission spectra. Emission spectra may be produced in the following ways (*a*) By flames of low temperature, *e.g.* by a spirit lamp or Bunsen burner, acting on solids, or the spray of solutions. The flame may be fed with chlorine, bromine, or iodine, or with hydrochloric acid when salts of the halogens are examined. (*b*) By flames of high temperature: blow-pipe, and oxyhydrogen flame. (*c*) By sparks in vacuum tubes containing residual gases or vapours. (*d*) By sparks of low tension acting on solids or solutions. (*e*) By sparks of high tension. (*f*) By solids in the electric arc. (*g*) By electric discharge on solids *in vacuo*; these are phosphorescence spectra.

As a rule, *line spectra* are the spectra of elements, *band spectra* are the spectra of compounds.

Salts of the alkali metals in the Bunsen flame emit line spectra characteristic of the metals, while the alkaline earth salts emit lines and bands which are characteristic of the metallic oxides. On the other hand, the burning of hydrogen and of hydrogen compounds causes the emission of more than 160 lines in the ultra-violet region, which can only be assigned to the vapour of water at a high temperature. Carbon is an element which emits bands in the coloured region, in hydrocarbon flames. A list of compounds which emit characteristic banded flame-spectra is given on p. 246. Erbia and erbium phosphate emit luminous bands when the solid substances are heated in a Bunsen or blow-pipe flame. Discharges in vacuum tubes sometimes emit a continuous spectrum; oxygen does so at the lowest temperature at which it is luminous. Most gases emit a banded spectrum with low tension sparks at ordinary pressures; the spectrum alters with diminution of pressure until finally nothing but a line spectrum is visible—for example, this is the case with air in the ultra-violet region. Sparks of low tension from solids, such as metallic electrodes, and from solutions, emit lines chiefly in the visible region, while those of high tension are generally richest in radiations of high refrangibility, chiefly in the ultra-violet region.

Low-tension sparks may be produced in two ways from solutions, first by wires of platinum moistened by the liquid, secondly by pieces of charcoal giving the flaming spark used by Bunsen. Many elements have been shown to emit a few bands or lines in the infra-red. The difference in action of high- and low- tension sparks is chiefly, if not entirely, due to temperature; the highest temperatures cause the emission of rays of the highest refrangibility. Solid elements, with few exceptions, yield spectra in the electric arc. The lines exhibited by some of the metals are exceedingly numerous. Reversed line spectra are common in the sun, and afford evidence of the presence of metals whose bright line spectra are coincident therewith. The number of bright lines seen reversed in the sun's spectrum indicates the strength of the evidence of the existence in the sun of certain elements.

As to the distribution of known kinds of matter in space, the following list shows the elements observed in the sun with the numbers of their reversed lines seen in the solar spectrum: Fe 730, Ti 230, Ca 94, Mn 85, Ni 102, Co 91, Cr 71, Ba 26, Na 11, Mg 17, Cu 7, H 5, Pd 5, V 4, Mo 4, Sr 4, Pb 3, U 3, Al 18, Ce 2, Cd 2, Be 2, Sn 1.

Methods of spectrum analysis. For efficient work with the spectroscope an instrument is to be preferred which admits plenty of light, has a rigid collimator, and immovable prism. Compound prisms of Grubb's and of Thollon's construction are among the best. The arc should be divided on the vertical edge of the prism-table or on an edge inclined at an angle of 45°. A vernier travelling over the arc and a mounted lens, for convenience in reading the scale and vernier, should be fitted near the telescope. A beautiful instrument made by the *Société Génevoise pour la Construction des Instruments de Physique* has a circle completely divided, and fittings for investigating ultra-violet spectra, either by photography or with a fluorescent eye-piece of Soret's design. It is provided with two verniers, and an automatic arrangement admitting of the prism being placed at the minimum angle of deviation for each ray under examination. This is necessary in order to secure the best definition. The instrument, of whatever form, should be capable of dividing and measuring the lines D^1 and D^2 of sodium, the first, second, and third lines of the yellow band; and in the carbon spectrum the first, second, third, and fourth lines of the green band, and the first, second, and third lines of the blue band, which are seen in the green inner cone of a powerful Bunsen burner. An instrument with a photographic scale, if it is sufficiently delicate, which is seldom the case, is of great use. One of these, constructed by Duboscq, was employed by Lecocq de Boisbaudran. A lens of short focus should be used to concentrate the light, from whatever source, upon the slit of the instrument. A test tube about 12 mm. diam., supported vertically, if filled with water and placed close to the slit of the instrument, answers this purpose. The telescope should be capable of easy movement without vibration, and be supported for two-thirds of its length from the object glass; neither clamping nor the use of the focussing screw should be capable of displacing its position. The rays should pass straight down the collimator and completely fill the lens. Before commencing any serious work, the capabilities of the instrument and its use for obtaining measurements should be carefully studied.

Supports of platinum wire fused into glass tubes are used for examining concentrated solutions and fused beads of salts in ordinary flames. Bunsen burners with steatite tops are particularly useful. Blow-pipe flames with a vertical direction, urged by bellows worked by the foot, are useful for examining the alkaline earths. Hydrogen gas from a constant generator made of lead and of large size is better than coal-gas for all flame spectra. Whether coal-gas or hydrogen be used, it is advantageous in examining salts of the alkaline earths, particularly chlorides, to pass the gas through a litre of strongest hydrochloric acid into a Bunsen burner, which is made of hard glass tube tipped with platinum. The flame is thus supplied with hydrochloric acid, and the chlorides are volatilised apparently without decomposition, so that they emit rays of great brilliancy which yield simple line spectra. For high temperatures a very small gas blowpipe may be supplied with oxygen. In this case the supports of platinum would be fused, and it has therefore been found convenient to use a wire of iridium, twisted into a loop, the compound being placed in the loop. In this manner manganese dioxide yields the bands of the dioxide, the spectrum of which is observed in the Bessemer flame. Calcium fluoride and copper oxide readily yield characteristic spectra. The alkaline earths yield very brilliant spectra, which are due to the metallic oxide in each case. When volatile substances, such as salts of lithium and the other alkalis, are under observation, it frequently happens that a difficulty in measuring their lines occurs owing to the evanescent appearance of their spectra; more lasting spectra may be produced by converting the volatile salts into silicates or borates by heating in a platinum spoon, or even in a porcelain crucible, with crystals of boracic acid. Beads of the borates will continue to illumine a flame for a lengthened period; with lithium and thallium, measurements have been made for as long as twenty minutes without renewing the material. Should the alkalis be accompanied by lime, strontia, or baryta, the spectra of these earths are suppressed, but towards the end of the observation sometimes the green colour of boric oxide appears. Sparks, both of low and high tension, may be used with Delachanel and Mermet's fulgurator. This instrument has the advantage of using very little solution, and losing none. Some solutions, such as salts of yttria, do not yield their characteristic spectrum to low-tension sparks, and it is necessary to strengthen the current by interposing a Leyden jar in the circuit, or, what is better, a pane of glass coated on either side with 930 square centims. of tinfoil. The spark should be 3 to 6 mm. in length. The lines of platinum, hydrogen, sodium, and a few of chlorine are visible, but these are known and are measurable. When the solution becomes contaminated with platinum, it may be removed and purified to be used over again if necessary. For such work it is best to use a coil which can yield sparks 170–180 mm. long in air.

For observations on ultra-violet spectra the arrangements described by Soret and by Cornu consist of an optical train of quartz and a prism of 60°, which is composed of two halves each of 30°; one of the two lenses and one half of the prism are cut from a right-handed crystal, the other corresponding parts from a left-handed crystal, so that the double refraction of one is corrected by that of the other. One half of the prism may be fixed on the collimator close to the lens, the other in front of the object-glass. For ordinary observations a fluorescent eye-piece is necessary, but generally photography is more convenient. Cornu has used lenses achromatised with colourless fluorspar, but this is not necessary, because the peculiarity of the camera employed by Hartley enables whole spectra to be accurately focussed on one plate if only one prism of 60 degrees be used. The camera back is sloped at an angle of about 22° to the normal, which brings one end of the plate nearest to the rays of shortest wave-length, and the locus of the foci of all the rays, from the least to the most refrangible, lies upon the plate. There is thus a saving of time in the observation of complicated spectra, with the additional advantage that angular measurements are abolished and linear measurements substituted. Moreover, an increased dispersion and separation of the rays is obtained. This arrangement is most suitable for use with two half-prisms of quartz of 30°. Six hundred lines in the spectrum of iron have thus been photographed with such excellent definition that a magnifying power of 25 diameters was used in their measurement. A quartz lens 75 mm. in diameter and of 75 mm. focus is placed in front of the slit. The camera back is so constructed that by a rack and pinion motion a succession of twelve or fifteen spectra may be taken on one plate. The lenses, which are not achromatised, are of 425 mm. focus for yellow light, and 50 mm. in diameter, the prisms being of corresponding dimensions.

Sparks of high tension obtained in the manner already described are necessary. They may be passed between metallic electrodes 3 to 6 mm. apart.

For photographing spectra yielded by solutions electrodes of graphite are used, or wicks of fine wire drawn from pure gold. The solution is placed in a small J tube; in the shorter limb the electrode is placed, and a platinum wire passes down the longer limb to make connection with the coil. By means of a pipette the tube is easily charged. The graphite electrodes are cut from good sound pieces of Ceylon or Siberian graphite, and are chisel-shaped, with grooves scored along them with the point of a pin. The opposite electrode may be of graphite or of any suitable metal. In order that the strongest discharges may pass from below upwards the lower should be the negative electrode. The admirable work of Lecocq de Boisbaudran on flame and spark spectra (*Spectres Lumineux*, 1874) not only gives the practical details, but maps of prismatic spectra, and the same applied to a scale of wave-lengths, as well as a complete description of the spectra and a description of each line. The publication proves to be all that a guide to the use of the spectroscope should be, but it deals only with the visible region. In photographing spark spectra the trouble of making drawings is unnecessary, since the photographs themselves are better than any reproduction; all that is required is a description and a map of the principal lines on the scale of wave-lengths. In photographing the spectra of solutions by means of graphite electrodes it is, of course, necessary to ascertain that the material does not yield any of the numerous lines in the spectrum of iron, generally speaking four lines of magnesium with wave-lengths 2801·1 to 2789·6 are visible. Although photography has been applied almost exclusively to the ultra-violet rays and to the infra-red, there is no reason why it should not be used for visible rays, since gelatin plates stained with cyanine, eosine, erythrosine, and some other dyes, render the plates sensitive to the orange, red, and yellow rays. Cyanine is a dye which is sensitive to most of the spectrum as far as the rays of very long wave-lengths.

On the sensitiveness of emission spectra. The following table gives the sensitiveness of the emission spectra of various elements in fractions of a milligram. It will be observed that radiations in different regions, and excited by different means, greatly vary in emissive power even with the same element.

On ultra-violet spectra. The conditions necessary in photographing ultra-violet spectra, are: 1st, a sensitive salt exerting an equality of action throughout the whole range of the spectrum; 2nd, a perfectly diactinic vehicle to hold the salt; 3rd, a process of development which will not exert a preferential action on any portion of the spectrum. These conditions are fulfilled by the use of silver bromide emulsion, the gelatin being of the purest description, and the image being developed by pyrogallol, hydroquinol, or hydroxylamine hydrochloride and caustic soda. The new developer eikonogen is suitable. Ferrous oxalate, as usually employed, is not to be recommended, because strong lines become developed much more strongly than weak lines. The exposure varies slightly with the sensitive nature of the plates, the width of the slit, the conducting power of the electrodes, the emissive power of the rays to be observed, and lastly with the excellence of the developer. Having once ascertained by comparative exposures how to obtain the best effect, there is very seldom any necessity for altering the exposure.

The following facts have been established regarding ultra-violet spark spectra: 1. When carbon or metallic electrodes, which emit short lines, are moistened or partially immersed in water, the short lines are lengthened. 2. The impurities in a metal, or the minute constituents of an alloy, generally appear as spectra composed of short lines. When both electrodes are of the same material, the impurities in minute proportion *appear at the negative pole only*, but when the proportion of the impurity or alloy is increased, the long lines are seen as short lines at both poles; a further increase in proportion brings them out as long lines. 3. Of the non-metallic elements, boron, carbon, and silicon exhibit line spectra. The line spectra of the elements are seen in spectra of borates and silicates, and in boracic and hydrofluosilicic acids. 4. The spectra of carbon and silicon may nearly always be detected in photographs taken from electrodes of metallic iron. 5. Insoluble compounds which are not volatile, such as ferrous sulphide, ferric oxide, and ferrous phosphate, do not yield spark spectra. Insoluble, though somewhat volatile, compounds, such as thallium chloride, yield a feeble spectrum of metallic lines. 6. With the exception of boron and silicon, the non metallic constituents of a salt do not affect the spark spectra of solutions. 7. The spectrum of a metallic chloride, nitrate, or sulphate yields spectral lines identical in number and position with the principal lines of the metal itself. Some of the short lines become long lines, but whether the spectra are produced by metallic electrodes or solutions their character is identical. 8. The effect of diluting solutions of metallic salts is first to weaken and attenuate the metallic lines, then, with a more extensive dilution, to shorten them, the length of the longest and strongest lines generally decreasing until they finally disappear. There are two lines in the spectrum of copper which disappear by attenuation only, and a similar pair of lines in the spectrum of silver behaves in like manner. Both pairs of lines have been observed as short lines in alloys containing very small quantities of these metals. 9. Accidental differences in the passage of the spark, or in the time of exposure of the photographic plate, when the normal period varies from half-a-minute to five minutes, do not cause sensible variations in spectra obtained from the same substances, under any ordinary circumstances. 10. Spectra of metallic electrodes and of solutions are liable to contain the lines of calcium, with wave-lengths

2967·3 and 3933, also occasionally those with wave-lengths 3736·5 and 3705·3. These calcium lines are due to dust when the electrodes are dry, and to impurity in the acids when solutions are prepared therewith and examined. 11. Five modified spectra have been observed in photographs taken from graphite electrodes, which apparently belong to no other element but carbon. The first and second were produced under identical circumstances, and were taken from dry points in air. The first contains 20 lines, the second only 12. The third was taken from wet electrodes in air, and consists of 20 lines, some of which are lengthened. The fourth was taken from dry electrodes in oxygen, and consists of 17 lines, some being much lengthened. The fifth was taken from dry electrodes in carbon dioxide, and consists of 18 lines, all much lengthened and strengthened (*T.* pt. i. 1884).

The examination of metals and alloys. When a metal is to be examined it may be filed, or hammered into electrodes of a convenient shape, and held between screw clips or between the points of cheap drawing pens. According to circumstances, both electrodes need not be of the same metal, but one may be of gold, platinum, or a tin-cadmium or lead-cadmium alloy containing in either case 20 p.c. of cadmium. Such an alloy gives convenient reference lines. If it be required to bring out the lines of the constituent of an alloy present in the metal in minute proportion, or present as an impurity in the metal, it is best to partially immerse the lower electrode in water contained in a small glass J tube, as if a solution were being photographed. Under these circumstances the short lines become much lengthened and consequently more prominent. The best form for electrodes is flat with curved edges, or even somewhat rounded discs, such as blow-pipe globules flattened.

The identification of lines in photographed spectra. When the spectrum of an alloy, metallic precipitate, or solution has been photographed, it is seldom easy to determine what substances are present or absent, partly on account of the complexity of the spectra and partly from the absence of colour. It is necessary in such cases to have recourse to one or both of the following methods of identification. (*a*) *Method of identifying the elements by lines photographed from a known specimen.* A series of photographs taken from metallic electrodes and from solutions should always be kept for reference. A substance may then be readily identified even when the wave-lengths of its lines are unknown, by superposing one photograph on the other, film to film, since there are but very few cases of actual coincidences of lines of similar character belonging to different elements. If this examination does not account for all the lines, it is necessary to proceed according to the next method. (*b*) *Method of identifying lines when comparison-spectra are not available.* By chemical processes of separation it is easy to ascertain what metals may be looked for. The wave-lengths of the unrecognised lines may then be ascertained by measurements and reference to an interpolation curve. The measurements need not be made with a micrometer unless great accuracy is required. It suffices generally to measure the spectra by means of an ivory scale with bevelled edges, the divisions on the scale being hundredths of an inch. With a strong magnifier we may read by judgment to tenths of a division or thousandths of an inch. The best form of magnifier is made like the compound eyepiece, of a microscope with cross hairs or fibres of cocoon silk in the field. The lens is placed very close to the surface of the scale and photograph, so that false readings caused by parallax are avoided. When all the lines in a photograph which have been recognised, or *vice versâ*, have been pricked off, the scale is very carefully adjusted so that it gives correct readings with lines of known wave-lengths at different parts of the spectrum, such for instance, with Nos. 9, 10, 11, 12, 17, and 25 of cadmium. In order to adjust the scale accurately, it is advisable to rule a line along the whole of the spectrum, which may be done when photographing by placing a wire at right angles to the slit, and one-third or one-fourth the length of the spark, above the lower electrode. The edge of the scale is applied to this line, and held in position by spring clips or screws. The scale numbers of the unrecognised lines are then read off, and by reference to the interpolation curve their oscillation-frequencies or their wave-lengths are obtained. From maps, or descriptions of spectra, accompanying a list of wave-lengths, the corresponding lines are selected and identified.

Descriptions of the spectra of the elements. Emission spectra. The spectra of non-metallic elements, particularly those which are gaseous, have been found to vary in character with the conditions under which they have been obtained. Thus N, O, C, Br, I, S, Se, Te, and P yield band spectra or line spectra, according to variations in temperature or pressure. The chlorides of B and Si likewise give line spectra due to B and Si; under certain conditions they emit spectra of their own. The fluted spectrum of carbon has given rise to great discussion. Swan, and later Ångström, attributed the bands to a hydrocarbon, so also did Morren, and Liveing a. Dewar, but they finally arrived at the conclusion first enunciated by Attfield, that the bands were caused by the element carbon. Van der Willingen, Plücker and Hittorf, Marshall Watts, Wüllner, Lockyer, and Fievez, have all adduced evidence of this. It appears, however, that a banded spectrum of cyanogen can be obtained which is distinct from that of carbon. Certain bands in the ultra-violet spark spectrum, which have been considered by Liveing and Dewar to be caused by cyanogen, have been observed by Hartley, and he is led to the conclusion that they are in reality carbon bands intensified by the presence of an atmosphere of nitrogen, but not cyanogen bands, for the reason that they cannot be obtained from various cyanogen compounds, such as soluble cyanides. They are always present when graphite electrodes are used in air, they are intensified when the electrodes are moistened, and they become particularly strong when concentrated solutions of chlorides, such as zinc chloride or calcium chloride, surround the electrodes; moreover, the strength of the bands increases with the strength of the solutions.

A review of the facts shows that large molecules give banded spectra, as is evident from the spectra of compounds, and various other considerations lead to the conclusion that the elements which give such are capable of existence in different molecular conditions, the most complex molecules emitting bands of rays, the simpler molecules emitting line spectra.

Hydrogen. When sparks are passed through hydrogen, four very well known lines appear. Huggins has observed the same in some stars, together with a remarkable series of lines in the ultra-violet, and it has been surmised that the whole series, visible and invisible, belong to the one element. Cornu has recently proved this to be the case. Fifteen lines in the visible and ultra-violet constitute the only true line spectrum of hydrogen.

The alkali metals, Li, Na, K, Rb, Cs. These metals are distinguished by the fact that most of their salts are decomposed in the flame, and the metal set free, or the metallic oxide formed from it, is sufficient to colour the flame intensely. The spectra are very simple, and all the principal lines are in the visible region. Their ultra-violet spark spectra are insignificant.

The alkaline earth metals, Ca, Sr, Ba. The spectra of these elements are obtainable by flames. When the chlorides are fused and heated in a flame supplied with hydrochloric acid, lines due to the metallic chlorides are visible. Without hydrochloric acid, the spectrum is at first a simple line spectrum, but subsequently bands, shown by Mitscherlich to be due to the oxides, take their place. Feeble sparks give line spectra with solutions of salts. In the ultra-violet, a series of well-marked groups of doublets and triplets is seen.

The magnesium group, Be, Mg, Zn, Cd. The element beryllium stands at the head of two families, that of the alkaline earths and the magnesium family. It occupies a position similar to that of lithium with regard to the alkali metals and the copper and silver family. Its spectrum is similar in many respects to that of lithium, being very simple and composed of isolated lines. There are two in the blue and five in the ultra-violet not visible in the flame, but obtainable by the action of condensed sparks. Magnesium and the compounds of the other metals of this group do not easily yield flame spectra, but give characteristic groups of lines when solutions are submitted to feeble or condensed sparks. In the ultra-violet these consist of well-marked groups of isolated lines, pairs, triplets, and groups of four and of five lines.

The aluminium elements, B, Al, Ga, In, Tl. Boron, which stands at the head of this group, gives a flame-spectrum only of its oxide, but the boron compounds, such as borates, emit three lines in the ultra-violet due to this element. Aluminium gives no flame spectrum, but gallium, indium, and thallium emit rays in the violet and green. Sparks taken from solutions of indium and thallium yield characteristic spectra in the ultra-violet consisting of many isolated lines and pairs of lines.

The tin elements, C, Sn, Ge, Pb. Carbon presents a very simple spectrum when condensed sparks are used; most of the lines are in the ultra-violet. It is a remarkable fact that under the same conditions the number of lines sometimes varies, and no satisfactory reason for this can be assigned. Four spectra of graphite have been mapped from photographs described as follows: 1. Dry electrodes in air. 2. Wet electrodes in air. 3. Dry electrodes in oxygen. 4. Dry electrodes in carbon dioxide. The strength and length of the lines vary under certain circumstances; in 1 the lines are all short, in 2 some lines are lengthened, in 3 some lines are much lengthened, and in 4 all the lines are lengthened and strengthened.

The spark spectra of tin, germanium, and lead contain numerous lines which are not characterised by any evident special grouping. The ultra-violet spectrum of germanium has yet to be photographed.

The group of rare earths, Ce, La, Di, Sm, Yt, Sc, Er, Tr. These elements give no flame spectra, and but weak spectra with feeble sparks. Ce, Di, Yt, Sm, Sc, Tr yield very complicated spectra to powerful sparks, the spectrum of cerium in the ultra-violet being remarkable for the immense crowd of lines. Yttrium and scandium chlorides give spectra composed of bands which are very characteristic in the visible region. Didymium, samarium, erbium, and thallium will be dealt with under the head of *Absorption spectra*. Lanthanum gives a large number of lines in the visible region, but very few in the ultra-violet.

The nitrogen elements, N, P, As, Sb, Bi, V. Nitrogen gives a large number of lines under the action of condensed sparks. The ultra-violet portion of the spectrum has been photographed. Nothing of the same kind is known of phosphorus. Phosphorus in a current of hydrogen gives a beautiful banded flame spectrum, especially when the flame is cooled. This reaction is exceedingly sensitive. The spectra of arsenic, antimony, and bismuth in the ultra-violet are very well marked, and they each contain a large number of lines, some of which are nebulous, others are mere dots, and there is a characteristic background of continuous rays. Vanadium yields spark spectra, with a large number of lines.

The chromium elements, Te, Cr, Mn. The line spectrum of tellurium obtained from the element is very complex, and by far the greater number of lines are in the ultra-violet; the character of the spectrum resembles those of arsenic, antimony, and bismuth. The chromium and manganese spectra are very complex and similar to those of the iron group.

The iron, nickel, and cobalt group. These metals present very complicated spectra when condensed sparks are employed in the visible, and more particularly the ultra-violet, regions. The grouping of the lines in the different spectra is similar.

The palladium, gold, and platinum group. These elements present complicated spectra, though less so than the foregoing. The strong lines of gold are few in number. These metals do not excel in emissive power. Feeble sparks with them give feeble spectra. Iridium gives a spectrum only with condensed sparks, which in the ultra-violet consists of a great crowd of lines.

The spectra of many elements, such as tungsten and uranium, have yet to be examined

thoroughly. It may here be remarked that elements usually associated by their natural occurrence, or by classification according to their chemical properties, exhibit spectra with characters in common.

A very important paper by Mitscherlich (*A.* 121, 459) first drew attention to the fact that a number of compounds emit distinct spectra, for the most part band spectra. A list of such compounds here follows, most of the spectra of which were originally described by Mitscherlich. Diacon also (*Thèses de Physique et de Chemie*, Montpelier, 1864), using a flame the interior of which was fed with chlorine, obtained distinct spectra of chlorides, such as those of the alkaline earths, gold, lead, iron, cobalt, and nickel; *the alkalis gave no spectra* excepting where they became converted into oxides or metal, as in the mantle of the flame.

Compounds emitting distinct spectra (Mitscherlich). *'Venetian-blind' or degraded band spectra. Flame.* BaO; $BiCl_3$, $BiBr_3$, BiI_3; B_2O_3; $CuCl_2$, $CuBr_2$, Cu_2I_2, CuO; $AuCl_3$; Fe_2O_3; MgO; MnO_2; $PbCl_2$, PbO; $MgCl_2$.

Plain band spectra. BaF_2, $BaCl_2$, $BaBr_2$; BiI_3; CaF_2, CaO; CuF_2; SrO.

Line spectra, or lines with bands. $BaCl_2$, $BaBr_2$, BaI_2; $CaCl_2$, $CaBr_2$, CaI_2; SrF_2, $SrCl_2$, $SrBr_2$, SrI_2.

Other observers have discovered and described specific spectra emitted by the following compounds:—Al_2O_3; feeble sparks (Wüllner and others). NH_3; flame (Dibbits). CO; spark (Plücker and others). CN; flame (Fox Talbot, Draper, Dibbits, and others). Er_2O_3 and $ErPO_4$; flame (Bunsen a. Bahr). MgO and hydride of Mg; flame and spark (Liveing a. Dewar). PH_3; flame cooled (Christofle a. Beilstein). $SiCl_4$, $SiBr_4$, SiI_4; spark (Plücker, also Salet). H_2O; flame (Liveing a. Dewar; Huggins).

Harmonic relations between the lines of a spectrum. The self-luminous nature of a molecule is connected with the vibrations of those parts of the molecule which are called atoms. The number of vibrations is indicated by the inverse wave-lengths of the lines in the spectra. The spectrum of iron contains more than 1,200 distinct lines, and it follows, therefore, that the molecule or its atoms must simultaneously excite as many different vibrations. We are acquainted with similar relations in acoustics. For instance, it has been observed by Hipkins that the simplest vibration of a pianoforte string will cause it to emit its own proper note, and as many as twenty-four overtones or harmonics. Johnstone Stoney first discovered such harmonics in spectra. The visible spectrum of hydrogen contains the three lines Hα wave-length 6563·9, Hβ = 4862·1, Hδ = 4102·4, these are the 20th, 27th and 32nd overtones of a vibration, of which the wave-length = 0·013127714 mm. But the fourth line Hγ = 4341, and the lines in the ultra-violet do not fall in with this system. Soret has calculated the harmonics of the three groups of triplets in the magnesium spectrum to be the 20th, 27th, and 31st harmonics of the fundamental vibration. Similar groups occur in the cadmium spectrum, which are the 20th, 23rd, 27th, and 31st of a fundamental vibration. Schuster has observed several harmonics in the spectrum of strontium; also in the spectra of bismuth, calcium, thallium, and gold. According to Mascart, sodium has five series of doublets which are the 132nd, 138th, 143rd, 158th, and 163rd harmonics. One of the most remarkable spectra is the absorption caused by chromyl chloride. Johnstone Stoney and Emerson Reynolds have shown that under great dispersion and lime-light illumination it gives a series of harmonics which are similar to those of a violin string, and of which the order lies between 628 and 733. Liveing and Dewar have observed that many ultra-violet spectra contain lines which are harmonically related, not so simply related perhaps as the harmonics of a uniform stretched string, but like the overtones of a string which is not of uniform thickness, or is loaded at different points, similarly related in origin though not exact harmonics. Lithium, potassium, calcium, magnesium, and zinc are such elements. The alkali metals have each one series in the visible spectrum, and another in the ultra-violet. It may happen in other cases that two or more such series overlap, and it may be very difficult to distinguish and separate them. There is a remarkable fact to be noted with regard to ultra-violet spectra, namely, that similar groups of lines, evidently harmonically related, are alternately sharp and nebulous in character.

Huggins discovered that the four hydrogen lines in the solar spectrum are part of a much longer series of lines which occur in the spectra of white stars. Cornu discovered the whole series in the spectrum of pure hydrogen, and Balmer showed that the whole series of lines can be expressed by the following formula:

$N_{m-2} = k\left(1-\frac{4}{m^2}\right)$, in which k is a constant for the whole series, and by substituting the whole numbers 3, 4, 5, 6, &c., for m, we obtain values for N which are the oscillation-frequencies of the successive lines.

Relations between the spectra of different elements. Lecocq de Boisbaudran has observed such a relationship between the lines in the different spectra of the alkali metals and their atomic weights, that he has been able to calculate the atomic weight of gallium from its spectrum. It may be stated that the atoms of greater mass vibrate more slowly, and therefore emit rays of proportionally greater wave-lengths. Ciamician made an extended series of observations on the spectra of elements usually classed together on account of their chemical properties, and he described several of these spectra as being homologous, that is to say, similarly constituted. A. Grünwald observed mathematical relations between the spectrum of water vapour and the line spectra of H and O, which led him to predict the existence of many lines in the spectrum of water vapour which had not been photographed. By prolonged exposures, Liveing and Dewar obtained photographs of a number of lines approximating very closely to those calculated by Grünwald.

Hartley, in 1883, observed the law of homology in the visible and ultra-violet spectra of the magnesium, zinc, and cadmium group. Elements with properties in common exhibit spectra with similar groupings of lines, but the dispersion of the lines and the refrangibility of the strong lines in each group vary with the atomic weights of the elements. In each spectrum the differences between the oscillation-frequencies of the individual lines of each triplet is a constant quantity. The law also applies to the series of doublets. The differences between the oscillation-frequencies of individual rays in the series of triplets increases with the atomic weights of the elements to which the triplets belong. A survey of these facts led to the conclusion that as the molecules of these elements contain but one atom, the atoms have a complex constitution, and that those elements the spectra of which are homologous are composed of the same kind of matter in different states of condensation, the molecules having similar modes, but different rates, of vibration. The law of homology has been studied by J. R. Rydberg, who it appears recognised it independently in 1885. J. S. Ames, in 1890, proved the perfect homology, line for line, of the arc spectra of zinc and cadmium. Kayser and Runge have shown that the series of triplets referred to in the magnesium, zinc, and cadmium spectra are in reality three series of harmonic vibrations, a principal series and two subordinate series overlying each other. The magnesium series they place along with those belonging to the calcium, strontium, and barium family, but according to the periodic law, the magnesium spectrum might be expected also to stand at the head of the spectra of the family which includes zinc and cadmium. The series of lines in the alkali and alkaline earth metals do not fall in with Balmer's law for the hydrogen lines. Homology has been observed

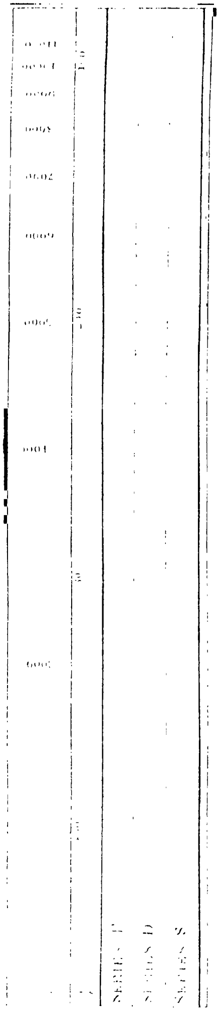

Fig. 1.

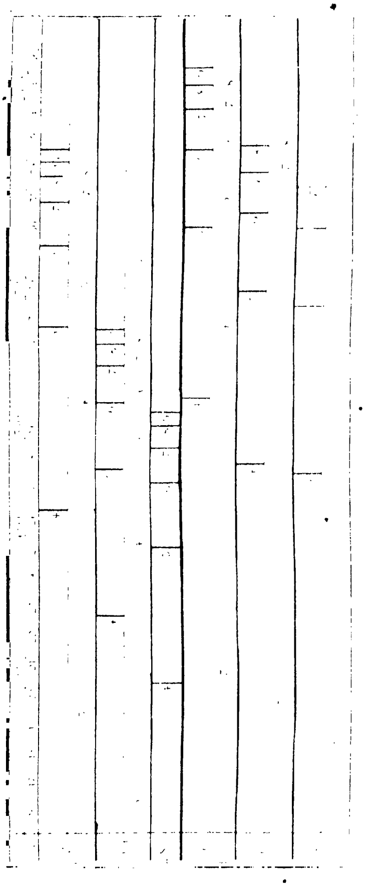

Fig. 2.

in the spectra of the following groups: lithium, sodium, potassium, rubidium, cæsium, also in aluminium, indium, thallium. Runge announces that doublets and triplets existing in the spectrum of an element can be arranged in series which show an appearance of great regularity, and are seemingly analogous to the overtones of a vibrating body (see figs. 1, 2, and 3). In fig. 1 the spectrum of sodium is shown with a scale of unequal parts, λ corresponding to wave-lengths, and a scale of equal parts $\frac{1}{\lambda}$ corresponding to oscillation-frequencies. The lines forming the entire spectrum are arranged in three series. Each line in the maps indicates a closely-placed pair of lines. Series P is the principal series, series D is the subordinate series of diffuse lines, series S the subordinate series of sharp lines. The three series are regular, the intervals between the lines decrease as the wave-lengths of the lines diminish from right to left. In fig. 2 we have similar maps, but the scales run the reverse way, from left to right. The principal and subordinate series of lines are shown in the spectra of Mg, Ca, Zn, Cd, and Hg. Corresponding lines in two different series of the same spectrum are numbered alike. The homology of the spectra is evidenced, and also variations following increase of atomic mass in elements of the same group. In fig. 3 the homology of the spectra of copper and silver is well shown. The difference of two consecutive oscillation-frequencies decreases as these values increase, and there seems to be a finite limit to the oscillation-frequencies of a series. If n represent whole numbers, the oscillation-frequencies of a series may, with great accuracy, be represented by the formula $A - Bn^{-2} - Cn^{-4}$, where A, B, C, are positive constants. B has nearly the same value for all the series of the different spectra. A is the limit towards which the oscillation-frequency tends when n increases. For elements that are chemically related the series are distinctly homologous, both in appearance of the lines and the values of A, B, C, and with increasing atomic weight they shift towards the less refrangible end of the spectrum. The spectra show relationships between the elements similar to those between their chemical properties.

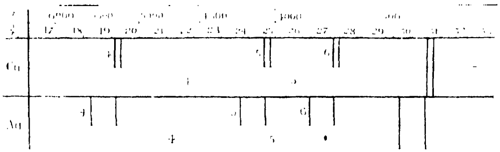

FIG. 3.

Quantitative analysis by the spectroscope. In 1862 W. A. Miller first attempted to apply the spectroscope to the quantitative estimation of the constituents of an alloy. Jansen, in 1870, proposed two methods of quantitative analysis. Champion, Pellet, and Grenier successfully applied a spectro-photometrical method to the estimation of alkalis. Lockyer and Roberts-Austen determined the composition of some homogeneous alloys of gold and silver, also of lead and cadmium, by comparison of their spectra with check pieces of known composition. Sir J. G. Alleyne estimated phosphorus in iron and steel, and Ballman attempted the estimation of lithium by the spectroscope. Liveing and Dewar made observations on a spectroscopic method of estimating sodium by measuring the width of the sodium lines. Hartley determined the different spectra emitted by solutions of different strengths, and found these constant when the ultra-violet lines were photographed. Accordingly, by comparison, the metals may be determined in solutions made from determinate weights of material, diluted to a definite volume. Quantitative determinations of the basic constituents of limestones, of copper in pyrites cinder, and of lead, silver, and copper in zinc blende, have been made with quantities of matter so small that no other method could have dealt with them. It will be seen later on, that absorption spectra are serviceable in quantitative analysis.

Spectra of the infra-red region and spectra of solids in vacuo. There are three methods of spectroscopy which have not yet been much employed. 1. The method of E. Becquerel for observing the infra-red rays. This is accomplished by the use of an eyepiece covered with Balmain's phosphorescent paint. When it is excited by exposure to a brilliant light, it glows, but as soon as any radiation of very low refrangibility falls upon it the phosphorescence is destroyed. 2. Abney observes the same rays by means of specially-prepared photographic plates, sensitive to exceedingly slow vibrations. Even the radiations from a kettle of boiling water can impress themselves permanently on his preparation of silver bromide. V. Schumann and also Waterhouse have used photographic plates prepared with cyanine, erythrosine, and other dyes for the same purpose with some success. 3. Crookes has made much use of the phosphorescent spectrum obtained by the action of an electric discharge in high vacua, and has made a most interesting series of observations on the rare earths by this means. Among other results he has proved the wide distribution of yttria, its occurrence in strontianite, coral, oyster shells, and limestones. He considers that there are several kinds of yttria with different phosphorescent spectra, but as they all give the same spectrum when excited by the spark in the usual manner, they must be considered as being derived from the same elementary yttrium.

Absorption spectra. **In dealing with absorption spectra, we may observe the effect on a continuous spectrum of (a) gases, (b) liquids, (c)** solids. When rays enter a transparent medium—either gaseous, liquid, or solid—they do not leave it in a condition identical with that in which they entered it. They may be either *partially absorbed* or *altered in refrangibility*. No known substance is capable of transmitting radiations of all known wave-lengths; those media which do not absorb appreciably any of the coloured rays, or any of the rays in the ultra-violet which are capable of being photographed, absorb a portion of the infra-red spectrum. It may be remarked that substances like air and water which in thin layers do not appear to absorb the rays in the visible spectrum, in thicker layers are seen to absorb the rays of a limited region. The A and B groups of lines in the solar spectrum have been shown to be due to oxygen in the atmosphere, while nine lines lying between the two D lines in the solar spectrum were observed, and proved by Josiah P. Cooke, in 1866, to be caused by water vapour in the atmosphere amounting to not more than 1·5 g. in 100 litres of air. With 0·18 g. only one line was visible, and with 0·55 g. two lines. The successful application by Piazzi Smyth of the spectroscope to weather forecasts is based upon such facts.

Many cases of absorption are known in the infra-red and in the ultra-violet, when no visible rays are absorbed. Colours may be either visible or invisible; since we must regard every substance which absorbs rays as coloured. The eye cannot always distinguish colour, because the most sensitive eye cannot observe the rays which are absorbed by its own aqueous humour, and are thus prevented from affecting the optic nerve. Hence the infra-red rays have no effect upon the retina, and most of the ultra-violet cannot affect it. The colour of a substance is determined by the combined effect of the rays which are not absorbed. Cobalt glass, which absorbs the yellow and green rays, transmits the red, blue, and violet, but as it transmits comparatively little of the red its colour appears blue. The purity of the light by which the substance is examined is of importance. Chromium solutions which are green by daylight are red by gaslight, because the yellow and red rays are predominant in gaslight, and as the red rays and the green are transmitted by pure white light, the dominant colour is red by light of less purity. There is but little importance to be attached to the general absorption of rays, but well-defined absorption bands afford evidence both of the composition and the constitution of substances.

The theory of absorption spectra. It is a well-known fact in acoustics that a vibrating musical instrument, a tuning-fork, or a stretched string, will communicate its vibrations to any similar instrument near to it which is capable of similar vibrations, and a sufficient number of strings or tuning-forks can entirely absorb the vibrations of a similar string or fork. In like manner when a molecule of a substance is capable of vibrating synchronously with a radiation, the rays received on the substance are absorbed by reason of the molecules being put in motion by the waves which strike them. The absorption is complete if the direction of vibration of the rays and of the molecule is the same, but the phase is opposite. A general absorption appears (in the ultra-violet at any rate) to be due to the vibration of the molecule, while selective absorption appears to be caused by the vibrations of atoms within the molecule. When a substance in solution absorbs all the rays of a certain region of the spectrum which fall upon it, it is because the molecules are vibrating synchronously with these rays, and the number of molecules present is sufficient to damp all the vibrations. When the rays traverse a smaller quantity of substance—as, for instance, when a solution is diluted—the number of molecules present is not sufficient to damp all the vibrations, and some rays pass through. If, however, certain atoms within the molecule are vibrating synchronously with certain rays, we shall have a selective absorption of these rays after the general absorption has been so weakened by dilution as to allow them to pass. It has been shown by Hartley that the vibrations of the atoms depend upon the rate of vibration of the molecule, or in other words, the rate of vibration of the molecule determines the rate of vibration of its parts. Four absorption bands in the three hydrocarbons benzene, naphthalene, and anthracene are evidence of this. The mean rate of vibration of the rays absorbed by naphthalene and anthracene is less than that of the rays absorbed by benzene, and the vibrations of the carbon atoms within the molecule are not independent of, but are a consequence of, the molecular vibrations; they must, in fact, be regarded as overtones or harmonics of the fundamental or molecular vibrations. When the rate of the fundamental vibration is reduced by an increase in the mass of the molecule, the rate of vibration of the carbon atoms is reduced in a similar ratio. Greater amplitude of vibration means a louder note, or in the case of luminous radiations a brighter light. Consequently the converse of this may be considered to hold good, that a greater intensity of absorption is caused by a greater amplitude of vibration in the molecules of the absorbing medium, the number of atoms or molecules remaining constant.

An examination of the three hydrocarbons benzene, naphthalene, and anthracene shows that the mean rate of vibration of the rays absorbed by benzene is greatest, naphthalene comes next, and anthracene is least; but the absorptive power is in the reverse order, that of anthracene being greatest. Hence we conclude that the amplitude of vibration is greater as the rate of vibration is slower (*C. J.* 1881). The approximate rates of vibrations of the three hydrocarbons are given as follows:—

	Mean wave-length of rays absorbed.	Molecular vibrations per second.	Molecular weights.
Benzene	2526	1,248 billions	78
Naphthalene	2687	1,177 „	128
Anthracene	3439	910 „	178

The various absorption spectra may be referred to in no better order than that of the refrangibility of the rays absorbed.

Infra-red absorption spectra. Abney and Festing have photographed rays extending down to λ 12000; the visible region ends about λ 7600. They studied the absorption spectra of water, hydrochloric acid, chloroform, carbon tetrachloride, cyanogen, and a number of hydrocarbons and their derivatives. The compounds containing hydrogen show the same group of lines, which, however, *do not appear in carbon compounds containing no hydrogen*; they do not all appear in some hydrogen compounds. The inference is that they belong to hydrogen. When oxygen is present as a part of hydroxyl it obliterates the rays between two of those lines which are due to hydrogen. When it forms part of the carbon nucleus of a compound, as it does in aldehyde, the spectrum is inclined to be linear, or the bands are bounded by well-defined lines. There appear to be characteristic bands which indicate the carbon nucleus of a series of substances. Certain radicles have a distinctive absorption lying near λ 7000 and others about λ 9000; thus in the three compounds C_6H_6, $C_6H_5.H_2N$, $C_6H_4(C_2H_5).H_2N$ we have the following coincident bands probably due to the benzene nucleus; the line λ 8670 is the principal one; λ 8670, λ 8670 to 8720, λ 8720 to 8860, a fourth band about λ 9300, a fifth about λ 10400–10660. In benzene and ethyl-aniline there occurs a band also at λ 10970 to 11050. If the line λ 8670 is associated with a band, it is almost certain to be caused by the benzene nucleus. Ethyl compounds are indicated by absorption at λ 7410, λ 8950 to 9030, 9040 to 9070, 9130 to 9180, 9270 to 9300·5, 9320 to 9420. The solar spectrum shows an absorption at λ 8660, and, with the exception of the line at 7410, the absorptions noted above have been observed to be coincident with bands or lines in the solar spectrum.

Visible and ultra-violet absorption spectra. The absorption spectra of the coloured region were long since carefully studied by Gladstone. These spectra pass gradually into the extreme violet and ultra-violet. In dealing with the subject it will be convenient first to consider the absorption caused by gases and vapours, elementary or compound, then the absorption by inorganic salts, and lastly the spectra of organic substances.

Elements which exhibit absorption spectra.

Gases and vapours.	Metals, the salts of which show banded spectra.
Br, Cl, I, O, ozone, K, Na.	Cr, Er, Sm, U, dysprosium, holmium, neodymium, prascodymium, thulium.

Compounds which exhibit absorption spectra.

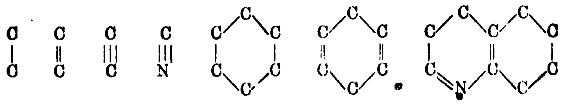
Gases and vapours.	Salts the acids of which show banded spectra.
ICl, IBr, NO_2, H_2O vapour, oxides of Cl.	Chromates } Ultra- Nitrates } violet. Nitrites (some); permanganates.

Organic suostances which exhibit absorption spectra. All benzenoid hydrocarbons and tertiary bases derived from the same. All haloid, hydroxyl, carboxyl, and amide, derivatives of benzenoid hydrocarbons. Cyanuric and uric acids, with colouring matters derived therefrom. Albumens and allied substances. Organic colouring matters of unknown constitution, such as chlorophyll and hæmoglobin. Many alkaloids and their derivatives, *e.g.*: Aconitine, pseudaconitine, japaconitine, morphine, narcotine, codeïne, papaverine, oxynarcotine, apomorphine hydrochloride, tetracetylmorphine, diacetylcodeïne, quinine, quinine sulphate, cinchonine sulphate, quinidine sulphate, cinchonidine sulphate, veratrine, piperine, brucine, strychnine.

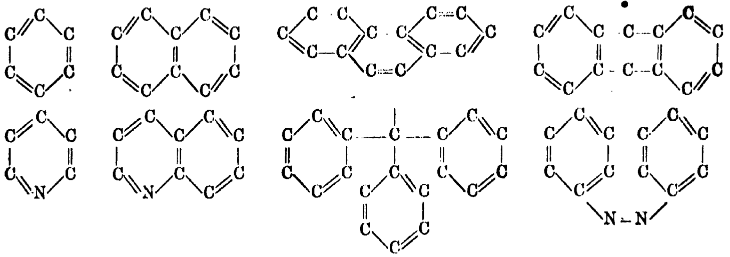
The relation of absorption spectra to the chemical constitution of carbon compounds. 1. Substances with a nucleus consisting of an open chain of carbon atoms transmit continuous spectra and are highly diactinic. Examples: the alcohols, acids, ethereal salts, haloid ethers, and the carbohydrates. 2. In homologous series the greater the number of carbon atoms the shorter the transmitted spectrum. 3. In substances with the same carbon nucleus that containing the most oxygen transmits the shortest spectrum, as, for instance, in acids the spectrum is shorter than in alcohols, and in dibasic shorter than in monobasic acids. 4. Substances with a closed chain nucleus when not more than two atoms of carbon are doubly linked transmit continuous spectra, but their absorptive power is much greater than that of open chain compounds; *e.g.* camphor, benzene hexachloride, and the terpenes, also hexahydropyridine. 5. The more closely the carbons in a closed chain are linked, the greater is the absorptive power of the molecule; *e.g.* the terpenes withstand dilution more strongly than benzene hexachloride, and camphor. 6. The carbon nuclei of benzenoid hydrocarbons possess strong absorptive power, and after great dilution exhibit absorption bands; *e.g.* four bands are seen in the spectrum transmitted by benzene when 1 part is diluted with 2,400 parts of alcohol, three bands in naphthalene with a dilution of 1 in 100,000 parts, one band in phenanthrene with 1 in 500,000 parts, and one band in anthracene with 1 in 5,000,000 parts of alcohol. 7. The introduction of radicles in place of hydrogen and of side-chains into the benzenoid nuclei diminishes the number of absorption bands, but increases their width and intensity. 8. The simple union of carbon to nitrogen does not cause selective absorption; *e.g.* in hydrocyanic acid and cyanides. 9. When a benzenoid nucleus contains an atom of nitrogen in place of an atom of carbon, the molecule exhibits absorption bands, and its absorptive power is generally not impaired, but is sometimes increased, *e.g.* picoline, pyridine, quinoline, and their derivatives. 10. Isomerides exhibit different spectra, *e.g.* the terpenes and isomeric benzene derivatives. 11. When the condensation of the carbon atoms in the quinoline nucleus is modified by the combination therewith of four atoms of hydrogen, the intensity of the absorption bands is reduced but is not destroyed. 12. Nitrogen combined with oxygen—as in nitroxyl, nitrites, and nitrates—exhibits absorption bands. 13. When several carbon atoms are united by oxygen and nitrogen atoms, the resulting compounds exhibit intense absorption bands, *e.g.* cyanuric acid, uric acid, and derivatives, including murexide. 14. Molecules of compounds—that is to say, molecules composed of dissimilar atoms—vibrate as wholes or units, and the fundamental vibrations give rise to secondary vibrations which stand in no visible relation to the chemical constituents of the molecule, whether these be atoms or groups of atoms. Hence it appears that a molecule is a distinct and individual particle which is not fully represented by our usual chemical formulæ.

since these only symbolise certain chemical reactions and fail to express any relation between physical and chemical properties. As certain molecular groupings are characterised by the absorption of rays of particular wave-lengths (absorption bands), it is evidently possible to draw conclusions as to the constitution of substances from their absorption spectra. Many of the foregoing statements may be usefully and clearly summarised by means of formulæ. These render evident how the optical properties of a compound are determined by the skeleton of carbon atoms.

Typical carbon nuclei, transmitting continuous spectra.



Typical carbon nuclei, exhibiting absorption bands.



Nuclei containing oxygen and nitrogen, exhibiting absorption bands. R representing any radicle.

On the cause of colour in organic compounds. According to O. Witt, the tinctorial character of aromatic compounds is conditional upon the simultaneous presence of a colour-producing group and a salt-forming group in the molecule. A group of atoms of the former kind he terms a *chromogen*, and of the latter a *chromophor*. He says: 'For instance, NO_2 is the chromophor of nitraniline and nitrophenol, but nitrobenzene is the chromogen of these bodies. The different nitrodiphenylamines are all acids and dye-stuffs, and their tinctorial power increases with the number of nitroxyls.' In this connexion it is of interest to study the relation of the hydrocarbons to the more complex compounds which are colouring matters derived from them.

If a source of light emits all luminous and invisible vibrations capable of being transmitted through 8 feet of air, a perfectly colourless substance will transmit these rays without impairing their intensity. A coloured substance is one which absorbs rays at either end of the spectrum, or selects rays of a definite wave-length from the middle of the spectrum. Every fluorescent substance is therefore coloured, and benzene, benzenoid hydrocarbons, phenols, and other derived compounds which exhibit selective absorption of the ultra-violet rays are coloured. The subtlety of the colour, however, is such that the eye cannot perceive it without the aid of photography or a fluorescent screen.

That which in the ordinary acceptation of the term is a coloured substance is merely one in which the absorption of rays extends into a region limited by the red and violet ends of the spectrum, or between wave-lengths 7000 and 4000. According to this view, the colour of a substance may be invisible to the unaided eye. As bands of selective absorption appear to be the effect of vibrations taking place within the molecules of a substance, and these are dependent upon the rate of vibration of the molecules themselves, they are called in general 'molecular vibrations.' If, then, it be desired to convert a substance such as benzene, the colour of which is invisible, into a compound with a visible colour, it is necessary to slacken its rate of vibration so that the molecule will absorb rays with oscillation-frequencies (inverse wave-lengths) occurring within the limits of visibility. That which is called a *chromogen* is an invisibly-coloured substance, and that termed a *chromophor* is an atom or group of atoms capable of so affecting the molecule as to reduce its rate of vibration, so that it absorbs rays within the limits of visibility. Under certain conditions of combination, nitrogen and oxygen are chromophors, hence also nitroxyl and hydroxyl; that is to say, they are themselves coloured either visibly or invisibly. When two benzene molecules are doubly linked by two nitrogen atoms, as in azobenzene, their mode of vibration is profoundly modified, and a brilliant colour as low down in the scale as the yellow rays is the result. A similar modification takes place when two atoms of oxygen replace two of hydrogen, as in quinone, which is of a golden-yellow colour. The effect of linking two or more benzene nuclei *by carbon atoms has been already dealt with*; the colours are not rendered visible, but the molecular vibrations are greatly reduced in rapidity, and the amplitude of the vibrations is much increased. That is to say, the absorption bands are transferred to less refrangible rays, and withstand a much larger amount of dilution. These modifications are both observed in the curve of benzene as modified in triphenylmethane. The vibrations of this radicle are reduced in rapidity in rosaniline hydrochloride, Hofmann's violet, iodine green, and other such derivatives in which the carbon nucleus remains intact.

There is a family likeness in the curves of azo-benzene, azo-naphthalene, chrysoïdine, and other derivatives of these substances, which is quite in accordance with these observations. In short, in a general way, the change of colour effected by any given series of reactions may be predicted from an inspection of the curve of molecular vibrations of any benzenoid hydrocarbon.

OPTICAL METHODS.—Section 3: ROTATION OF THE PLANE OF POLARISATION OF LIGHT.—When a ray of plane polarised light is passed through a plate of quartz cut at right angles to its optical axis, it is found that the plane of polarisation of the emergent ray is not coincident with that of the incident ray; the angle through which the plane has been rotated is called the *angle of rotation.* If the rotation takes place in the same direction as that in which the hands of a watch move when the face of the watch is looked at, the quartz is said to show *dextrorotatory power*; if the rotation is in the opposite direction, the quartz is said to show *lævorotatory power.* The symbol + is used to express dextrorotation, and the symbol − to express lævorotation. Substances which rotate the plane of polarisation of a ray of light passed through them are said to be *optically active.*

The *polarimeter* is an instrument wherein a ray of light can be polarised, the position of the plane determined, the ray passed through a determinate quantity of an optically active substance, and the position of the plane of the emergent ray determined.

The angle of rotation depends upon (1) the nature of the active substance, (2) the thickness of the layer of the substance through which the light passes, (3) the wave-length of the light used, and in most cases (4) the temperature.

The composition of the substance examined must then be known; the length of the column of liquid used if the substance be liquid, or the thickness of the layer if the substance be a solid, must be measured; the temperature must be noted—observations ought to be made at a common temperature; and monochromatic light should be employed.

Suppose we are dealing with a liquid carbon compound. Let l = length of column of liquid in decimetres, d = sp.gr. of liquid (referred to water), and α = angle of rotation of the plane of polarisation of light of stated wave-length; then $[\alpha] = \frac{\alpha}{l.d}$.

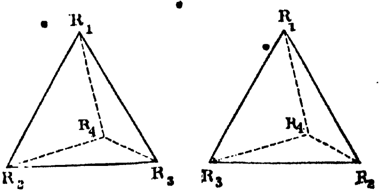
The value of $[\alpha]$ is usually called the *specific rotatory power* of the substance. It is customary to indicate the light employed by placing a letter to express the wave-length below the bracket; thus $[\alpha]_D$ means spec. rot. power for light of wave-length D. The spec. rot. power of a liquid as thus defined is the angle through which the plane of polarisation of a ray of light of stated wave-length is rotated by passing through a column one decimetre long of the liquid containing one g. of the substance in 1 c.c.

If a solid compound is to be examined, it must be dissolved in an optically inactive solvent. In this case l = length of column of solution in decimetres, d = sp. gr. of solution, p = g. of optically active substance in 100 g. of solution; then, assuming that the solvent is without influence on the rotatory power of the dissolved substance, $[\alpha] = \frac{100\alpha}{l.p.d}$. The question as to the effect of an inactive solvent on the rotatory power of an active substance in solution will be examined later (p. 257).

Connections between optical activity and constitution. Landolt (*Handbook of the Polariscope*, English trans.) has divided substances which rotate the plane of polarisation of a ray of light into three classes: (1) those which are active only when in the form of crystals; (2) those which are active only when liquid or in solution; (3) those which are active both as crystals and also in solution or in the liquid state. The only substance at present known to belong to the third class is strychnine sulphate. The liquid crystals examined by Lehmann (*Z. P. C.* 4, 462; 5, 427) probably belong to the first class.

The optical activity of carbon compounds. All compounds which exhibit optical activity unconnected with crystalline form—in other words, all compounds which are optically active when liquid or in solution—are compounds of carbon. Le Bel (*Bl.* [2] 22, 337) was the first (1874) to trace a definite connection between the optical activity and the constitution of carbon compounds. He was followed by van't Hoff (*Bl.* [2] 23, 295 [1875]). The subject has been much advanced by van't Hoff in his pamphlet, *La Chimie dans l'Espace*, and more especially by a small book published in 1887, *Dix Années dans l'Histoire d'une Théorie* (translated into English by Marsh, and published in 1891, entitled *Chemistry in Space*).

The hypothesis of Le Bel and van't Hoff connects optical activity with the presence of one or more *asymmetric* atoms of carbon in the molecule of the active compound. An *asymmetric* atom of carbon is one which is in direct combination with four different atoms or radicles, these atoms or radicles being arranged so that any three are similarly situated with regard to the fourth. The conception of the asymmetric atom carries with it the conception of the arrangement in space of the parts of the molecule. The asymmetric atom of carbon is supposed by van't Hoff to be placed in the centre of a regular tetrahedron, and a different radicle is supposed to be held by the carbon atom at each summit of the tetrahedron. Two forms of this arrangement may exist, and these forms are geometrically different. Neither is superposable on the other. They bear to one another the relation of an object to its image, or of the right hand to the left, as shown in the figure.



This arrangement corresponds to the *enantiomorphous* (non-superposable) form of crystals. Ammonium malate, for instance, crystallises in two non-superposable forms, which differ in exactly the same way as the molecules of two geometrical isomerides, each containing an asymmetric carbon atom and both having the composition $CR_1R_2R_3R_4$, are supposed to differ. If one of the isomerides $CR_1R_2R_3R_4$ rotates the plane of polarisation to the right, the other rotates to the left. If this hypothesis is to be accepted, every compound of carbon which is optically active must contain at least one asymmetric carbon atom. So far as investigation has gone, this deduction from the hypothesis has been confirmed (*v.* van't Hoff, *Dix Années &c.*, 31; Landolt, *Handbook*, 25 *et seq.*). Further, it has been found that compounds which do not themselves contain asymmetric carbon atoms are inactive, although they are derived from optically active compounds.

There is no doubt that compounds exist which contain asymmetric carbon atoms but do not affect the plane of polarisation of a ray of light. At first sight this fact might be supposed to be irreconcileable with the hypothesis; but the recognition of the existence of inactive compounds containing asymmetric carbon atoms has led to a most ingenious and interesting development of the hypothesis.

Some inactive compounds containing asymmetric carbon atoms can be separated each into two optically active isomerides, one of which is dextrorotatory and the other is lævorotatory. Some inactive compounds which contain asymmetric carbon atoms cannot be separated into active isomerides. Racemic acid, which can be resolved into dextrorotatory and lævorotatory tartaric acid, is an example of the first of these classes, called *inactive resolvable compounds*;

mesotartaric acid, which cannot be resolved into active isomerides, is an example of the second class, called *inactive non-resolvable compounds.*

Inactive resolvable compounds are said, in the language of van't Hoff's hypothesis, to be *inactive by external compensation*; inactive non-resolvable compounds are said to be *inactive by internal compensation.*

To understand these expressions consider the formulæ $(\mathrm{R}_3\mathrm{R}_2\mathrm{R}_1)C.C(\mathrm{R}_1\mathrm{R}_2\mathrm{R}_3)$ and $(\mathrm{R}_2\mathrm{R}_3\mathrm{R}_1)C.C(\mathrm{R}_1\mathrm{R}_3\mathrm{R}_2)$; an italicised C represents an asymmetrical atom of carbon. Each formula contains two asymmetric carbon atoms, and both carbon atoms in either formula are united to the same radicles; in the first formula each C is united to the radicles R_1, R_2, R_3, and $\mathrm{C}(\mathrm{R}_1\mathrm{R}_2\mathrm{R}_3)$; in the second formula each C is united to the radicles R_1, R_3, R_2, and $\mathrm{C}(\mathrm{R}_1\mathrm{R}_3\mathrm{R}_2)$. The structure represented by one of these formulæ is the reflected image of that represented by the other: hence if one of these geometrically isomeric compounds is dextrorotatory, the other will be lævorotatory, and both will rotate the plane of polarisation to the same degree. But if a compound were formed by the combination of equal numbers of molecules of these two geometrical isomerides, that compound would be inactive, for the tendency to right-handed rotation of one part of the compound molecule would be exactly neutralised by the equal tendency to left-handed rotation of the other part. Moreover, if the inactive compound were split into two compounds, one consisting of molecules of the form represented by the first of the above formulæ, and the other of molecules of the form represented by the second formula, then each of these compounds would be optically active, and the compounds would be active in opposite directions. The hypothetical inactive compound $\begin{array}{l}(\mathrm{R}_3\mathrm{R}_2\mathrm{R}_1)C.C(\mathrm{R}_1\mathrm{R}_2\mathrm{R}_3)\\(\mathrm{R}_2\mathrm{R}_3\mathrm{R}_1)C.C(\mathrm{R}_1\mathrm{R}_3\mathrm{R}_2)\end{array}$ would be said to be *inactive by external compensation.*

Racemic acid, which is optically inactive, can be resolved into dextrorotatory and lævorotatory tartaric acids. Both tartaric acids have the formula $\mathrm{C}_2\mathrm{H}_2(\mathrm{OH})_2(\mathrm{CO}_2\mathrm{H})_2$; the hypothesis we are considering represents one of these acids as $(\mathrm{H.OH.HOOC})C.C(\mathrm{COOH.OH.H})$; and the other acid as $(\mathrm{H.COOH.OH})C.C(\mathrm{OH.COOH.H})$; and the hypothesis represents racemic acid as made up of an equal number of molecules of the two active acids, and therefore as a substance which is inactive by external compensation.

But suppose the molecule of a compound contained two asymmetric carbon atoms, both united to the same radicles but having one half of the molecule the reflected image of the other, then the tendency to right-handed rotation belonging to one part of this molecule would be neutralised by the tendency to left-handed rotation belonging to the other part of the molecule; the molecule as a whole would be incapable of rotating the plane of polarised light, and the compound would be *inactive by internal compensation*. The general formula of such an inactive compound is $(\mathrm{R}_2\mathrm{R}_3\mathrm{R}_1)C.C(\mathrm{R}_1\mathrm{R}_2\mathrm{R}_3)$.

A compound of this type cannot be resolved into active isomerides, because a resolution into parts is only possible by splitting the molecule, removing one of the radicles, and so destroying the asymmetry of one, or both, of the atoms of carbon. Mesotartaric acid, which is non-resolvable, probably belongs to this class of compounds; it may have the formula

$$(\mathrm{H.COOH.OH})C.C(\mathrm{COOH.OH.H}).$$

The hypothesis therefore provides for the existence of two classes of optically inactive compounds, both containing asymmetric carbon atoms; the members of one class are resolvable into active isomerides, the members of the other class cannot be so resolved.

Those compounds which contain in their molecules more than one asymmetric carbon atom, each of which atoms is united to the same radicles, whether these radicles are arranged in space in exactly the same way, relatively to each carbon atom, or not, are called by van't Hoff *symmetrical compounds*; and the term *unsymmetrical compounds* is used to designate those which contain more than one asymmetric carbon atom each of which is united to different radicles. The typical formulæ for symmetrical compounds containing two asymmetric carbon atoms are
$(\mathrm{R}_1\mathrm{R}_2\mathrm{R}_3)C.C(\mathrm{R}_3\mathrm{R}_2\mathrm{R}_1)$, $(\mathrm{R}_1\mathrm{R}_3\mathrm{R}_2)C.C(\mathrm{R}_3\mathrm{R}_2\mathrm{R}_1)$, &c.

The typical formula for an unsymmetrical compound containing two asymmetric carbon atoms is $(\mathrm{R}_1\mathrm{R}_2\mathrm{R}_3)C.C(\mathrm{R}_4\mathrm{R}_5\mathrm{R}_6)$.

Unsymmetrical compounds may be either active or inactive; if inactive, they must be inactive by external compensation, and therefore they must be resolvable into pairs of active isomerides. Symmetrical compounds may be active or inactive; if inactive, they may be inactive by external, or by internal, compensation, and therefore they may be either resolvable or not resolvable.

An unsymmetrical compound containing *n* asymmetric carbon atoms may exist in 2^n isomeric forms, which will always be grouped in pairs, one being dextrorotatory and the other lævorotatory. A symmetrical compound containing *n* asymmetric carbon atoms may exhibit $\frac{1}{2}2^n$ active isomeric forms, grouped in pairs of opposite rotatory power, and may also exist in $\frac{1}{2}2^{\frac{n}{2}}$ non-resolvable inactive modifications (van't Hoff; *Dix Années* &c., 54-5).

There are three general methods for separating inactive resolvable bodies into their dextrorotatory and lævorotatory isomerides.

In the first method advantage is taken of the differences between the actions of certain minute organisms on the two active isomerides. The second method proceeds by treating the inactive compound with an active body with which one of the isomeric constituents of the inactive compound combines more readily than the other. The third method consists in separating the inactive body into two active isomerides by crystallisation at a definite temperature (van't Hoff, *l.c.* 63-69).

Racemic acid, which is an inactive compound, can be resolved into equal quantities of right- and left-handed tartaric acid by each of the three methods. When *penicillium* is allowed to act on a dilute solution of ammonium racemate, lævorotatory ammonium tartrate is found in the solution after a time, the dextrorotatory tartrate having been destroyed by the action of the organism. When a quantity of active cinchonine sufficient to neutralise half of a determinate quantity of racemic acid is added to a solution of the racemic acid, crystals of lævorotatory cinchonine tartrate are obtained, and dextrorotatory tartaric acid remains in solution. When a solution of racemic acid is neutralised by soda, and another equal quantity is neutralised by ammonia, and the solutions are mixed, and evaporated at a temperature slightly below 28°, crystals of two forms are obtained; one set of crystals is dextrorotatory, and the other is lævorotatory, sodium-ammonium tartrate. Van't Hoff (*l.c.* 69) has shown that sodium-ammonium racemate is changed to a mixture of the active isomeric tartrates by heating the dry salt with water, in the ratio $\mathrm{NaNH_4.H_4C_4O_6.H_2O:3H_2O}$ (the salt crystallises with $\mathrm{H_2O}$), to a little under 27°, and that the reverse change is effected by heating the mixed tartrates to a little above 27°. The changes may be represented thus—

$$\mathrm{2(NaNH_4.H_4C_4O_6.4H_2O) \rightleftarrows 2(NaNH_4.H_4C_4O_6.H_2O) + 6H_2O.}$$

The racemate crystallises with $\mathrm{H_2O}$, and the tartrates with $\mathrm{4H_2O}$. Slight variations of temperature above or below 27° determine the direction in which the change shall occur.

The change of inactive sodium-ammonium racemate to a mixture of the active tartrates, and *vice versâ*, is very similar to some changes which occur among inorganic compounds; for instance, when a mixture of $\mathrm{MgSO_4.7H_2O}$ and $\mathrm{Na_2SO_4.10H_2O}$ is heated to a little above 21°, it is changed to the double sulphate $\mathrm{MgNa_2(SO_4)_2.4H_2O}$, and water, and this double sulphate is resolved into the two single sulphates at a little under 21°; these changes may be represented thus:—

$$\mathrm{MgSO_4.7H_2O + Na_2SO_4.10H_2O \rightarrow MgNa_2(SO_4)_2.4H_2O + 13H_2O.}$$

Van't Hoff calls the temperature at which such a chemico-physical change as this occurs the *transition-point* of the system (*v. Z. P. C.* 1, 165, 227).

Extension of the hypothesis of van't Hoff and Le Bel. The hypothesis of van't Hoff and Le Bel connects the power of rotating the plane of polarisation of a ray of light primarily with the configuration of the parts of molecules, but it points to the formation of molecular aggregates, without change of molecular structure, as a cause of the disappearance of optical activity. Although optical activity is primarily dependent on the arrangement of the parts of certain molecules, and although we cannot assign a definite part of the total rotatory power of a molecule to each atom, or to each group of atoms which together form the molecule, nevertheless a consideration of the constitution of optically active compounds shows that the amount of the activity of any compound is dependent on the greater or less differences between the four radicles which are in direct union with the asymmetric carbon atom or atoms in the molecule of that compound. The greater the differences between the radicles the greater will be the asymmetry of the molecule, and, therefore, the greater will be the rotatory power. An attempt has been made by P. A. Guye (*C. R.* 110, 714) to connect the degree of asymmetry of the molecule of an optically active compound with the mass of each radicle, and the distance of its centre of gravity from the centre of figure of the tetrahedron. When the molecule is asymmetric, the centre of gravity will not be situated on any one of the six planes of symmetry of the tetrahedron. So long as the substitution of one radicle by another does not move the centre of gravity of the molecule to the other side of one of the planes of symmetry of the tetrahedron, Guye supposes that the rotatory power is increased or diminished, but is not changed in sign, by such substitution; but that a change of sign of the rotatory power accompanies a substitution which results in moving the centre of gravity of the molecule from one side to the other side of one of the planes of symmetry of the tetrahedron. Guye gives about fifty cases to which he has applied his hypothesis successfully. The derivatives of tartaric acid afford the most complete example.

Replacement of the acidic hydrogen of tartaric acid by alcoholic radicles is accompanied by increase of rotatory power, and the greater the molecular weight of the replacing alkyl the greater is the increase of rotatory power; thus—

Methyl tartrate	$[\alpha]_D =$	$+2{\cdot}14$
Ethyl	„	$7{\cdot}66$
Propyl	„	$12{\cdot}44$
Isobutyl	„	$19{\cdot}87$

Replacement of the hydroxylic hydrogen of the acid by benzoyl moves the centre of gravity to the other side of the plane of symmetry which is situated between the COOH and OH groups; this replacement is accompanied by a change of sign of the rotatory power. But if the H of the COOH group is now replaced by one alkyl group, the centre of gravity is moved back towards the plane of symmetry already mentioned, and the rotatory power is diminished. Thus—

Dibenzoyl	tartaric acid	$[\alpha]_D =$	$-117{\cdot}7$
Methyl salt of		„	$88{\cdot}8$
Ethyl	„	„	$60{\cdot}0$
Isobutyl	„	„	$42{\cdot}0$

If acetyl is used in place of benzoyl the rotatory power changes its sign, but the value of the lævorotation of diacetyl tartaric acid is less than that of dibenzoyl tartaric acid; the replacement of acidic hydrogen in the diacetyl acid by alkyl radicles decreases the rotatory power, and, as the alkyl radicles of large molecular weight exert a greater effect than the acetyl group, and an effect in the opposite direction, the rotatory power again changes its sign. Thus—

Diacetyl	tartaric acid	$[\alpha]_D =$	$-23{\cdot}1$
Methyl salt of		„	$14{\cdot}3$
Ethyl	„	„	$+1{\cdot}0$
Propyl	„	„	$6{\cdot}5$
Isobutyl	„	„	$10{\cdot}3$

Crum Brown (*Pr. E.* 17, 181) has tried to connect the greater or less rotatory powers of different active compounds with differences between the constitutions of the substituting radicles. Crum Brown admits the influence of the masses of the radicles, but he tries to show that their constitution must also be taken into account. If two methyl groups are introduced into dextrorotatory tartaric acid, the salt thus obtained is still dextrorotatory; in this change two CO.OH radicles have been changed into two radicles CO.O.CH_3. If now this dimethyl tartrate is treated with acetyl chloride, a strongly lævorotatory dimethyl diacetyl-tartrate is obtained; in this change the CO.O.CH_3 groups remain, and two OH groups have been changed to two groups O.CO.CH_3. In the first change, the introduction of the group CO.O.CH_3 for H altered the rotatory power but did not change its sign, in the second change the introduction of the group O.CO.CH_3 changed the sign of the rotatory power; therefore, Crum Brown argues, the effect of the radicle O.CO.CH_3 on the rotatory power is greater than the effect of the isomeric radicle CO.O.CH_3. As the masses of these two radicles are the same, it is evident that the constitution of the substituting radicle affects the rotatory power of the compound.

The specific rotatory powers of compounds often change more or less with small changes in certain physical conditions. Some active bodies become inactive by heating, and at another temperature the change is sometimes reversed. The values of the rotatory powers of active bodies dissolved in inactive solvents are dependent on the nature and the quantity of the solvent used (*v. post*, p. 257); the rotatory power of a solution sometimes changes on keeping until a constant value is attained (*v.* Landolt's *Handbook of the Polariscope*, 62). This readiness to change shown by the rotatory powers of carbon compounds finds some explanation in van't Hoff's hypothesis, and especially in the development of it made by Wislicenus. According to Wislicenus (*Kön. Sächsischen Ges. der Wiss.* 14, 1) the arrangement of the four radicles attached to an asymmetric carbon atom is conditioned chiefly by the affinities of these radicles for one another in the sense that those radicles which have the greatest mutual affinity will tend to get as near as possible to one another; but besides those configurations which are conditioned by the affinities of the radicles, and which will be comparatively stable, other configurations will probably exist conditioned by the temperature and by the collisions of other molecules—for instance, the molecules of the solvent—and these arrangements will be relatively unstable. These unstable forms may be optically active, as they are only geometrically different from the stable forms, but their rotatory powers will probably differ from those of the stable forms. This way of looking at the question of optical activity enables us to connect the fact that active compounds easily undergo changes in the values of their rotatory powers with the conception which the hypothesis of van't Hoff and Le Bel furnishes of the cause of optical activity.

Molecular rotatory power. The notion of molecular rotation, as the product of the specific rotation into the molecular weight of a substance, was introduced by Wilhelmy (*P.* 81, 527). Krecke (*J. pr.* [2] 5, 12) proposed to define *molecular rotatory power* as $[m] = \frac{m}{100} \times \frac{\alpha}{l.d}$, where m = molecular weight of compound, and α, l, and d have the same meaning as before (p. 253); m is divided by 100 to obviate the use of inconveniently large numbers.

Krecke endeavoured to generalise the relations between the values of $[m]$ for certain compounds and bodies derived from, or closely connected with, these compounds. Some years before Krecke's attempt, Mulder (*Z.* 1868. 58) put forward a statement to the effect that optically active compounds contain certain active radicles, which may be transferred to other active atomic aggregations, and the rotatory powers of the new bodies bear a simple relation to those of the original radicles. Krecke, on the basis of further experimental results, modified and extended Mulder's statement. Krecke announced two generalisations:

(i.) 'When an optically active body forms a compound with an inactive body, or when it is altered by the action of chemical reagents, either the molecular rotatory power of the body is unchanged, or the molecular rotatory power of the new substance is a simple multiple of that of the parent substance.'

'(ii.) 'The molecular rotatory powers of isomerides are multiples of one and the same value.'

Most of Krecke's values were obtained from measurements of substances in solution, and, as we shall see in another paragraph, the results of such measurements are trustworthy only in a few cases. Landolt (*B.* 6, 1073) made a careful examination of the rotatory powers of tartrates in solution; he came to the conclusion that the value of $[m]$ for tartrates containing a single atom of a monovalent metal is double the value of $[m]$ for free tartaric acid, and that $[m]$ for tartrates containing two atoms of a monovalent metal is three times $[m]$ for the free acid. In this case, Krecke's first statement was confirmed.

In 1885, Oudemans (*v. P. B.* 9, 635) arrived at the conclusion that the compounds of active bases with inactive acids, and also the compounds of active acids with inactive bases, follow the simple law that 'the molecular rotatory power of a salt, in fairly dilute solution, is independent of the nature of the inactive part of the salt.' This result has been confirmed by the measurements of camphorates and tartrates made by Landolt, of salts of cholic acid by Hoppe-Seyler, of malates by Schneider (*A.* 207, 286), and of camphorates by Hartmann (*B.* 21, 221).

This result indicates that the rotatory powers of salts in solution are not affected, to anything like the extent that the rotatory powers of liquid compounds are affected, by the nature of the radicles which compose them. The rotatory power of a salt in solution approaches to being an additive property, whereas the rotatory power of a liquid compound is a constitutive property (*cf.* Ostwald, *Lehrbuch*, 1, 499 [2nd ed.]).

Optical activities of bodies in solution. The specific rotatory power of an active substance in an inactive solvent has been defined (p. 253) as $[\alpha] = \frac{100\alpha}{l.p.d.}$, where l = length of column of solution in decimetres, d = spec. grav. of the solution, and p = g. of active substance in 100 g. of the solution. This formula is expressed in more general terms as $[\alpha] = \frac{n.\alpha}{l.g.d.}$, where n = g. of solution containing g g. of the substance; in this case, 1 c.c. of the solution weighs d g. and contains $\frac{g.d.}{n}$ g. of the active substance.

This formula assumes that the rotatory power of the dissolved active substance is not affected by the inactive solvent. In 1838 Biot (*A. Ch.* [3] 36, 257; *cf.* 59, 206) found that the rotatory power of tartaric acid in aqueous solution increased with increasing dilution; that solutions, of equal concentration, of the same active substance in different inactive solvents had different rotatory powers; and that the same inactive solvent raised the rotatory powers of some active substances, and decreased the rotatory powers of others. Results similar to those of Biot were obtained by Oudemans (*A.* 166, 65; 182, 33), Hoorweg (*Maanblad voor Natuurwet,* 3, 12 [1873]), and Hesse (*A.* 176, 89, 189).

Landolt (*A.* 189, 241; *B.* 21, 191; *Handbook of the Polariscope*, 80-94) made many observations on the effect of inactive solvents on the rotatory powers of active substances; he came to the conclusion that the specific rotatory powers of such solutions are expressed by equations of the following forms: $[a] = A + Bq$, or $[a] = A + Bq + Cq^2$, or $[a] = A + \frac{Bq}{C+q}$, where A, B, and C are constants, and q is weight of active substance in 100 pts. of the solution. Which formula must be employed is discovered from the results of several observations made with solutions of different concentrations in different solvents. In some cases the observed values of $[a]$ for liquid compounds agree with the values calculated from series of observations of a for solutions of the same compounds. Thus Landolt got the following results:—

Active substance	$[a]_D$ observed	$[a]_D$ calculated from observations on solutions in					Max. diff.
		(1) EtOH	(2) MeOH	(3) H_2O	(4) C_6H_6	(5) AcOH	
Dextro-ethyl tartrate	8·31	8·27	8·42	8·09	—	—	−·22
Dextro-turpentine	14·15	14·87	—	—	—	—	+·72
Lævo-turpentine	37·01	36·97	—	—	36·97	36·89	−·12
Lævo-nicotine	161·55	160·83	—	161·29	—	—	−·72

It is not possible to determine with certainty whether the true values of $[a]$ for solid compounds can be determined from observations on solutions of such compounds. In some cases the values obtained seem to approach constancy when the solutions become very dilute; but according to Pribram (*B. B.* 1887. 505; *B.* 20, 1840), who used a very delicate method of measuring, $[a]$ does not certainly attain final constant values in aqueous solutions of tartaric acid, nicotin, and cane sugar, even with very great dilution. R. von Sonnenthal (*Z. P. C.* 9, 656) determined $[a]$ for dilute aqueous solutions of normal and acid tartrates of K, Na, Li, and NH_4; he found that $[a]$ decreased as dilution increased, but that when the solutions became very dilute (c. ·4 to ·2 p.c. salt in solution) $[a]$ began to increase as dilution still further increased. The conclusion come to by von Sonnenthal was, that a change in the state of the dissolved tartrates occurred when more water was added to the very dilute solutions; this change was supposed to be of the nature of dissociation. The dilution whereat the change occurred was found to depend on the nature of the metal of the tartrate, and on the solubility in water of the salt used; the greater the atomic weight of the metal, the greater was the concentration whereat the change began, and the greater was the difference from the normal state of the salt. Schneider (*A.* 207, 257) found that the rotation of an aqueous solution of malic acid was right-handed in concentrated solutions, left-handed in dilute solutions, and at 34 p.c. was equal to zero. These observations, and others of a similar character, seem to me to show that observations of the rotatory powers of solutions of solid compounds cannot be applied, at least not in all cases, to draw conclusions concerning the connections between the rotatory powers and the chemical constitutions of the compounds themselves. There is undoubtedly an action of some kind between the molecules of the active dissolved substance and the molecules of the inactive solvent. Molecular aggregates of the solid substance may be broken down by the solvent, or the solvent may form a series of unstable compounds with the dissolved substance, or the solvent may bring about changes in the configuration of the atoms which form the molecule of the dissolved body, or the dissolved compound may be electrolytically dissociated into ions by the solvent. Some of these actions may occur in certain cases, and others in other cases. The action of much water on active salts dissolved therein seems to consist in the electrolytic dissociation of the salts into their ions.

Magnetic rotatory power. Following observations made in 1871 by A. de la Rive (*A. Ch.* [4] 15, 57), Becquerel in 1877 (*A. Ch.* [4] 22, 5) made a number of measurements of the rotatory powers of liquid substances, and of salts in solution. The subject was taken up by Perkin in 1882, since which time a series of memoirs by this investigator has appeared (*C. J.* 45, 421; 49, 777; 51, 808; 53, 561; 55, 680; 59, 981; 61, 800). The methods employed in the measurements are based on the discovery which Faraday made in 1846 (*T.* 1846. 1), that most transparent bodies acquire the power of rotating the plane of polarisation of a ray of light when they are brought within the action of a magnet, or of an electric current which is made to pass round the body so that its plane is at right angles to the direction of the ray of light. Faraday showed that the amount of rotation is proportional to the strength of the current, or the intensity of the magnetic action, and to the length of the layer through which the light passes, and that it is dependent on the temperature and on the nature of the substance examined. Perkin has worked with liquid compounds and with solutions. The fluid to be examined was placed in a glass tube about 103 mm. long, and 9 mm. diameter, the ends of which were closed by circles of glass cemented on; the ends of the tube were let into the pole-pieces of a large electro-magnet. Sodium light was employed by Perkin. (For a description of the apparatus, and the various precautions and corrections, *v.* Perkin, *C. J.* 45, 421–445.) Perkin calculates his results so that the observed rotations of liquid compounds are referred to lengths of the liquids related to one another in the same proportion as the molecular weights of the gaseous compounds obtained by vapourising the liquids; the results when thus calculated represent the magnetic rotatory powers of quantities of the various compounds proportional to the weights of the gaseous molecules of these compounds.

The molecular rotation of water is taken as unity. If r is the rotation of unit-length of liquid, and r' is the rotation of the same length of water under the same conditions, then $\frac{r}{r'}$ is the specific rotation of the liquid; and sp. rot. $\times \frac{\mathrm{M}}{\mathrm{M}'.d}$ is the molecular rotation, where M = molecular weight of substance, M′ = molecular weight of water, and d = relative density of substance. The calculation may be expressed by one equation, thus: $(\text{Mol. R.}) = \frac{r.\mathrm{M}}{r'.\mathrm{M}'.d}$.

About 200 compounds have been examined by Perkin, the observation of r being repeated five to ten times for each compound, and the specific gravity of each being determined with great care.

Magnetic molecular rotatory powers of liquid carbon compounds. In strictly homologous normal series of carbon compounds, each increment of CH_2 produces a constant increase in molecular rotatory power, amounting to 1·023. But when the addition of CH_2 is accompanied by a change in the distribution of the atomic interactions the change of Mol. R. is not constant; the change from a normal paraffin, $CH_3.nCH_2.CH_3$, to the next higher isoparaffin, $CH(CH_3)_2.nCH_2.CH_3$, raises Mol. R. by 1·023 + ·105; in the change from a normal acid to the next higher iso- acid of the same series, CH_2 has a different value; and so on. When Cl is substituted for H in a hydrocarbon the mol. rotatory power increases, but each Cl atom has a different value from the others. So with the replacement of H in a hydrocarbon by OH; each OH group has its own value, the effect on Mol. R. of the second OH being less than that of the first. So again with the group NO_3; the second NO_3 does not increase Mol. R. so much as the first.

The molecular rotatory powers of various homologous series of carbon compounds may be expressed by the general formula

(Mol. R.) = $c + n1{\cdot}023$, where n = number of atoms of C in the molecule of any stated compound in the series, and c is a constant for each series. Perkin gives the following table (*C. J.* 45, 574):—

Mol. R. of members of homologous series.

Paraffins	C_nH_{2n+2}	·508 + n1·023
„ iso-	„	·621 „
Alcohols	$C_nH_{2n+2}O$	·699 „
„ iso- and sec.	„	·844 „
Oxides	„	·642 „
„ iso-	„	·932 „
Aldehydes	$C_nH_{2n}O$	·261 „
„ iso- and ketones	„	·375 „
Acids	$C_nH_{2n}O_2$	·393 „
„ iso-	„	·509 „
Formic ethereal salts (Et, and higher)	„	·495 „
Acetic „ „	„	·370 „
„ „ „ iso-	„	·485 „
Methyl salts	„	·273 „
Ethyl „ and higher salts	„	·337 „
„ „ iso-	„	·449 „
Succinic methyl salts	$C_nH_{2n-2}O_4$	·093 „
„ ethyl „	„	·196 „
„ „ „ iso-	„	·422 „
Chlorides	$C_nH_{2n+1}Cl$	1·988 „
„ iso- and sec.	„	2·068 „
Bromides	$C_nH_{2n+1}Br$	3·816 „
„ iso- and sec.	„	3·924 „
Iodides	$C_nH_{2n+1}I$	8·011 „
„ iso- and sec.	„	8·099 „
Ethyl salts, unsaturated	$C_nH_{2n-2}O_2$	1·451 „

These results indicate that the molecular rotatory power of a liquid carbon compound is not the sum of certain constant values belonging to each atom or atomic group, but that it depends, to some extent, on the arrangement of the atoms which form the molecule. This result is confirmed by the outcome of attempts to assign values to the atomic rotatory powers of oxygen and carbon. The following data are given as examples of such attempts.

The atomic rotatory power of hydrogen may be deduced thus:

1. Mol. R. C_nH_{2n+2} = Mol. R. $nCH_2 + H_2$; but Mol. R. $nCH_2 = n1{\cdot}023$.

The value thus deduced for At. R. of H = ·254.

2. Mol. R. C_nH_{2n+2} *minus* Mol. R. C_nH_{2n+1} = At. R. of H.

Thus, $\text{Mol. R. } C_3H_8 = 3{\cdot}577$

$$\text{Mol. R. } C_3H_7 = 3{\cdot}323 = \text{Mol. R. } \frac{C_6H_{14}}{2}$$

$$\text{At. R. of } H = \cdot 254$$

Now, At. R. of O = Mol. R. CH_2 *minus* At. R. of H × 2 = 1·023 − ·508 = ·515.

By applying similar methods to the data for compounds of O, the following results are obtained:

At. R. of O in alcoholic OH = ·194
" " carboxylic OH = ·137
" " " CO = ·261

The At. R. of Cl varies according to the series of compounds considered, and also as one or two atoms of H are replaced by one or two atoms of Cl, according as the H replaced is in one part of the molecule or in another part, and so on. Two values are obtained for At. R. of N, according as the atom of N is directly connected with 3 or 5 other atoms or groups. The general conclusion is that changes in the magnetic molecular rotatory powers of liquid carbon compounds are intimately connected with changes in molecular structure, so that any cause which alters this structure also alters the rotatory power.

In *C. J.* 61, 800, Perkin gives an elaborate study of the constitution of ethyl acetoacetate and allied compounds, which elucidates very clearly the connections between the constitution and the magnetic rotatory powers of carbon compounds.

Mol. R. of compounds in presence of water. Perkin has used determinations of Mol. R. of certain compounds before and after addition of water, to throw light on the question whether hydrates are formed by the action of water on these compounds (*C. J.* 49, 777; 51, 808; 55, 680). In all measurements of Mol. R. the molecular rotatory power of water is taken as unity; if therefore a compound is formed by the addition of water to another compound, the Mol. R. of the new compound might be expected to be nearly equal to that of the original compound, *plus* one unit for each molecule of water added; if the observed Mol. R. is distinctly less than that calculated in this way, the difference may be explained by supposing that the formation of the new compound has been accompanied by a rearrangement of the atoms of the reacting molecules.

The following are examples of the application of this method. In each case the compound and water were mixed in the ratio shown by the formula given, and the Mol. R. of the product was determined; the Mol. R. of the product was then calculated by adding one unit for each molecule H_2O to the observed Mol. R. of the original compound without water.

Compound and water	Mol. R. observed	Mol. R. calculated for	Diff.
$HCO_2H.H_2O$	2·666	$H.CO_2H + 1 = 2{\cdot}671$	− ·005
$CH_3CO_2H.H_2O$	3·554	$CH_3CO_2H + 1 = 3{\cdot}525$	+ ·029
$C_2H_5CO_2H.H_2O$	4·512	$C_2H_5CO_2H + 1 = 4{\cdot}462$	+ ·05
$H_2SO_4.H_2O$	3·188	$H_2SO_4 + 1 = 3{\cdot}315$	− ·127
$H_2SO_4.2H_2O$	4·113	$H_2SO_4 + 2 = 5{\cdot}188$	−1·075
$H_2SO_4.3H_2O$	5·064	$H_2SO_4 + 3 = 6{\cdot}188$	−1·124
$HNO_3.2{\cdot}67H_2O$	3·656	$HNO_3 + 2{\cdot}67 = 3{\cdot}85$	− ·194
$CCl_3.CHO.H_2O$	7·037	$CCl_3.CHO + 1 = 7{\cdot}591$	− ·554

Perkin thinks that when water is added to formic, acetic, and propionic acids in the ratio of equal molecules of water and acid, either a hydrate or a mixture is formed in each case; but that when H_2SO_4 and H_2O react in about the ratio $H_2SO_4{:}H_2O$ (or a little more H_2O than this), a rearrangement of atoms occurs with formation of a new compound of S, O, and H (perhaps $SO(OH)_4$); and that reactions of this nature, involving rearrangements of atoms, also occur between HNO_3 and H_2O, and $CCl_3.CHO$ and H_2O.

The following data are interpreted by Perkin to mean that a solution of NH_3 in water, or in alcohol, 'simply consists of the solvent and ammonia':

$$\text{Mol. R. } NH_3 + 2{\cdot}1H_2O = 3{\cdot}91$$
$$\text{"} \quad 2{\cdot}1H_2O = 2{\cdot}1$$
$$\text{"} \quad NH_3 \quad 1{\cdot}81$$
$$\text{Mol. R. } NH_3 + 2{\cdot}18C_2H_6O = 7{\cdot}886$$
$$\text{"} \quad 2{\cdot}18C_2H_6O = 6{\cdot}06$$
$$\overline{1{\cdot}826}$$

Mol. R. of acids and salts in aqueous solutions. Perkin (*C. J.* 55, 680; 59, 981) gives Mol. R. for HCl as 2·187. This is arrived at by finding values for At. R. of H and Cl from observations of Mol. R. of various chlorides of alcoholic radicles. By similar methods of calculation values for Mol. R. of HBr and HI were obtained. The three results are:

Mol. R. HCl = 2·187
" HBr = 4·016
" HI = 8·211

The value for HCl was confirmed by measuring Mol. R. of HCl dissolved in isoamyl oxide; the result was Mol. R. HCl = 2·24.

Values were then obtained for the three acids in aqueous solutions. The numbers increased as dilution increased; in any case they were much larger than the values obtained by the method stated above. The following table gives the minimum and maximum values for each acid:

Mol. R. in aqueous solutions.	Maximum.	Minimum.
HCl	4·419 (15·63 p.c. HCl)	4·045 (41·7 p.c. HCl)
HBr	8·519 (15·47 p.c. HBr)	7·669 (65·99 p.c. HBr)
HI	18·451 (31·77 p.c. HI)	17·769 (67·02 p.c. HI)

It is evident that the magnetic mol. rotatory powers of HCl, HBr, and HI in aqueous solutions are much greater than the values calculated from those obtained for the same three acids from observations made with compounds of them with C and H; in the case of HCl, the value of Mol. R. in aqueous solution is much greater than the value for the same compound in solution in isoamyl oxide. There must be an action of some kind between water and these three compounds.

It has been shown already that addition of water to H_2SO_4 results in a value for the Mol. R. of the acid different from that observed for the pure acid itself; but in this case addition of water reduces the Mol. R. of the acid. A similar reducing effect was noticed as accompanying the addition of water to HNO_3.

Perkin was unable to explain these results. Ostwald, however, has shown that they are in keeping with the electrolytic dissociation hypothesis (*C. J.* 59, 198). According to this hypothesis strong acids are dissociated in aqueous solutions into their ions. Aqueous solutions of HCl, HBr, and HI, contain the ions $\overset{+}{\mathrm{H}}$ and $\overset{-}{\mathrm{Cl}}$, $\overset{+}{\mathrm{H}}$ and $\overset{-}{\mathrm{Br}}$, and $\overset{+}{\mathrm{H}}$ and $\overset{-}{\mathrm{I}}$, each with its electric charge. The observed rotatory powers of these solutions, *minus* the value for the water contained in them, therefore represent the rotatory powers of these ions, and not of the compounds themselves; and the rotatory powers of these ions are considerably greater than those of the non-dissociated compounds. An aqueous solution of H_2SO_4, or HNO_3, must also contain dissociated, electrically charged, ions—according to the hypothesis; but Perkin's observations (*ante*, p. 259) show that the rotatory powers of the ions of these acids are slightly smaller than those of the acids themselves.

Now, the hypothesis of electrolytic dissociation asserts that the metallic salts of acids are dissociated into electrically charged ions in dilute aqueous solutions; hence determinations of Mol. R. for aqueous solutions of metallic salts of HCl, HBr, HI, H_2SO_4, and HNO_3 ought to give results different from the values obtained for these salts themselves. But the values obtained for aqueous solutions of salts of HCl, HBr, and HI ought, on the whole, to be greater than the calculated values, whereas the values obtained for salts of H_2SO_4 and HNO_3 ought, generally, to be slightly smaller than the calculated values. This deduction is partly confirmed by Perkin's results.

The values of Mol. R. for NH_4Cl is calculated by Perkin as follows (*C. J.* 55, 743). The value for HCl is found from determinations of Mol. R. of alcoholic chlorides, which enable values to be found for H and Cl in combination; the value for NH_3 is taken as 1·818, which is the mean of the values found from observations on NH_3 in water and alcohol (*ante*, p. 259); the sum of the values for HCl and NH_3, with the subtraction of ·5, gives the calculated Mol. R. of NH_4Cl. The number ·5 is taken from the sum of the values for HCl and NH_3 because observation has shown that this is about the difference between the values for N^{III} and N^{V}, and in NH_3 the N atom is trivalent, while in NH_4Cl it is supposed to be pentavalent. The values for the other salts of NH_4 are calculated in a similar way. Perkin's results for Mol. R. of NH_4I, NH_4Br, and NH_4I show that practically the same values are obtained for solutions containing from c. 30 to c. 60 p.c. of the salts. The results with the six salts were as follows:

—	Calculated	Observed, in aqueous solutions	Differences
NH_4Cl	4·305	6·096	+ 1·791
NH_4Br	6·096	7·997	+ 1·901
NH_4I	8·149	9·896	+ 1·747
NH_4NO_3	2·298	2·320	+ ·022
NH_4HSO_4	3·433	3·455	+ ·022
$(NH_4)_2SO_4$	4·551	4·980	+ ·439

With regard to NH_4NO_3 and the two sulphates, it is to be observed that the calculated values are found by adding the values for the acid and the base (NH_3), then deducting ·5 for the change of N^{III} to N^{V}, and then deducting ·2 for the change from the free acid and base to the combination of these compounds; now, ·5 is merely an approximate value for the change from N^{III} to N^{V}, and ·2 is also merely a rough approximation for the value of the process of combination of acid and base. As the differences between the observed and calculated values for NH_4Cl, NH_4Br, and NH_4I are large, small errors in the method of calculating Mol. R. for these compounds do not materially affect the differences in question; but as the differences are small in the cases of the nitrate and sulphates, small errors in the method of calculating Mol. R. for these compounds do materially affect those differences. Moreover, the observations of Mol. R. of the nitrate and the sulphates of ammonium in aqueous solutions were made with a single solution in each case (59·7 p.c. NH_4NO_3, 66·6 p.c. NH_4HSO_4, and 40 p.c. $(NH_4)_2SO_4$); hence it is not certain that the numbers set down as the values of Mol. R. of these compounds in aqueous solutions are the true values.

Perkin has also (*C. J.* 59, 981) made measurements of the magnetic mol. rotatory powers of the ammonium salts of formic, acetic, and propionic acids in aqueous solutions, and compared the results with the values calculated. He gives the results as follows:

—	Observed, in aqueous solution	Calculated	Differences
Ammonium formate	3·363	3·489	− ·126
" acetate	4·247	4·343	− ·096
" propionate	5·259	5·280	− ·021

The interpretation which the electrolytic dissociation hypothesis gives of these results is that, as in their aqueous solutions the salts examined are dissociated into their ions, and as the observed results are smaller than the calculated values, therefore the magnetic mol. rotations of the ions of HCO_2H, CH_3CO_2H, and $C_2H_5CO_2H$ are slightly less than the rotations of the acids themselves (*v.* Ostwald, *Z. P. C.* 9, 513; *cf.* Ostwald, *C. J.* 59, 201).

But it seems to me that the numbers given by Perkin as the calculated values of Mol. R. for the three salts cannot be accepted as correct. For these values were found by adding the values of Mol. R. for the free acids to the value for free NH_3; no deduction was made for the change of rotation accompanying the combination of the acid and the base, and no deduction was made for the change of N^{III} to N^{V}. Either these values cannot be accepted as the true values, or the values calculated for the salts of NH_4 with the halogen acids, and with HNO_3 and H_2SO_4, are not correct (*ante*, p. 260). If the values of Mol. R. for the salts of formic acid &c. are calculated by the same method as was used in the cases of the other salts of ammonium, then the results of this investigation are as follows:

—	Observed in aqueous solution	Calculated	Differences
Ammonium formate	3·363	2·789	+·574
„ acetate	4·247	3·643	+·604
„ propionate	5·259	4·580	+·679

If these results are accepted, then the differences are much greater than those given by Perkin, and they are in the opposite direction.

Measurements of the Mol. R. of formic, acetic, and propionic acid in aqueous solution would enable the question to be settled as to the effect of water on these acids; at present it seems that the magnetic rotations of the ions of these acids would be found to be greater than the rotations of the acids themselves.

This conclusion is confirmed by combining the results obtained by Perkin (*C. J.* 59, 986) for Mol. R. of sodium salts of formic and other acids with the value calculated by him for sodium (*C. J. Proc.* 1890. 141). In the following table I have calculated the values for the salts as Perkin calculated the values for NH_4Cl, NH_4NO_3 &c., by deducting ·2 from the sum of Mol. R. of acid and At. R. of Na, and then further deducting ·254 for the loss of H:

	Observed in aqueous solution	Calculated	Differences
Sodium formate . .	2·347	1·775	+·572
„ acetate . .	3·281	2·629	+·652
„ propionate .	4·308	3·566	+·742
„ butyrate. .	5·332	4·576	+·756

In a more recent communication (*C. J.* 63, 57) Perkin gives the Mol. R.s of aqueous solutions of H_2SO_4, HNO_3, Na_2SO_4, and $LiNO_3$ of varying degrees of concentration. His results show that the Mol. R.s of these solutions do not vary with dilution in the same way as the electrical conductivities vary. The most dilute solution of H_2SO_4 examined by P. contained c. 9·2 p.c. H_2SO_4, and the most dilute solution of HNO_3 contained c. 22·5 p.c. HNO_3. Now it has been shown repeatedly, by Ostwald and others, that measurements of the conductivities of fairly conc. solutions of acids and salts cannot lead to just conclusions regarding the amount of electrolytic dissociation of the compounds in solution; hence it is not to be expected that the amount of dissociation of H_2SO_4 and HNO_3 should be calculable from the Mol. R.s of these compounds as deduced from observations on solutions so concentrated as those used by Perkin. What the observations of P. show is that the magnetic rotations of certain compounds diverge from the calculated results in all cases wherein electrolytic dissociation occurs. The laws which express the electric dissociation of compounds are to be deduced from the study of very dilute solutions, and as no measurements of magnetic rotations have yet been made for such solutions, it is not justifiable to draw detailed quantitative conclusions concerning the electrolytic dissociations of compounds from the measurements of the magnetic rotations of those compounds which P. has made.

XI. THERMAL METHODS. Determinations of the quantities of heat which are produced, or which disappear, in chemical reactions help to elucidate the nature of these reactions. There are two sides to every chemical operation; there is a change in the form or distribution of matter, and a change in the form or distribution of energy. Light is thrown on the second of these changes by thermo-chemical investigations, and the connections between the two parts of the complete occurrence, and the mutual dependence of both, are thus made clearer. Thermo-chemical methods rest on the principle of the conservation of energy. When a chemical reaction occurs, heat may be produced, electricity generated, mechanical work done by expansion, and sound or radiant heat may leave the system; the sum of these forms of energy, added to the energy remaining in the system at the close of the reaction, must equal the energy originally present in the system at the moment when the change began. As a large part of the energy set free during any chemical reaction usually takes the form of heat, it follows that measurements of the heat produced during the reaction must give information regarding the differences between the initial and final energies of the system. The primary aim of thermo-chemical measurements is to determine such energy-differences; the secondary aim is to connect these differences with the differences of composition, constitution, and properties which the reacting systems undergo.

The loss or gain of energy which accompanies the passage of a system from one defined state to another is independent of any intermediate states through which the system may pass. This generalisation was proved experimentally for several cases, so far as heat energy was concerned, by Hess in 1840 (*P.* 50, 385); the generalisation may be deduced from the principles of energy. On this statement rest the methods for determining the thermal values of chemical changes when these values cannot be observed directly.

Notation used in thermo-chemistry. Thomsen's notation is followed in this DICTIONARY; the formulæ of the reacting substances are taken to represent grams of these substances—thus HCl means 36·5 g. of hydrogen chloride; the formulæ are inclosed in a square bracket, and the figures representing the number of atoms of each element are placed above the symbols; the reacting substances are separated by a comma. The unit of heat is that quantity which raises the temperature of 1 g. of water at c. 18° through 1°. Ostwald, in his *Lehrbuch der Allgemeinen Chemie*, employs a unit almost exactly 100 times greater than this, viz. the quantity of heat given out by 1 g. of water in cooling from 100° to 0°. The symbol Aq means that a large quantity of water is present. Thus [H,Cl] = 22,000 means that 22,000 gram-units of heat are produced when 1 g. H combines with 35·5 g. Cl; [H,Cl,Aq] = 30,660 means that 30,660 gram-units of heat are produced when 1 g. of H combines with 35·5 g. of Cl in presence of a large quantity of water in which the HCl dissolves; [HCl,Aq] = 17,320 means that 17,320 gram-units of heat are produced when 36·5 g. of HCl dissolve in a large quantity of water; and [HClAq,KOHAq] = 13,750 means that the neutralisation of 36·5 g. HCl, dissolved in much water, by 56 g. KOH, dissolved in much water, the products of neutralisation being allowed to remain in solution, is accompanied by the production of 13,750 gram-units of heat. The symbol H_2O is used as in ordinary notation to represent 18 g. of water; thus $[As^2O^5,3H^2O] = 6,800$ means that 6,800 gram-units of heat are produced during the formation of 284 g. H_3AsO_4 by the combination of 230 g. As_2O_5 with 54 g. water; and $[As^2O^5.3H_2O,Aq] = -800$ means that 800 gram-units of heat disappear during the solution of 284 g. H_3AsO_4 in a large quantity of water. Thomsen's notation does not indicate the products of the reaction, the thermal value of which is set down; nor does it show the physical states of the reacting substances, or of the products of the reaction, except in the one case when the substances are dissolved in much water. Ostwald (*Lehrbuch*) uses the ordinary notation, and adds figures to express the quantities of heat which are produced or disappear in the reactions; he employs ordinary type for liquids, thick type for solids, and italics for gases. Thus, $H_2 + Cl_2 = 2HCl + 44,000$ means that 44,000 gram-units of heat are produced when 2 g. gaseous hydrogen combine with 2 × 35·5 g. gaseous chlorine to form 2 × 36·5 g. gaseous hydrogen chloride; $2H_2S + 2\mathbf{I}_2 = 4HI + 2\mathbf{S} - 34,000$ means that 34,000 gram-units of heat disappear when 2 × 34 g. gaseous hydrogen sulphide react with 2 × 254 g. solid iodine to form 4 × 128 g. gaseous hydrogen iodide and 2 × 32 g. solid sulphur; and $2\mathrm{H_2SAq} + 2\mathrm{I_2Aq} = 4\mathrm{HIAq} + 2\mathbf{S} + 34,000$ means that 34,000 gram-units of heat are produced when 2 × 34 g. hydrogen sulphide dissolved in much water react with 2 × 254 g. iodine dissolved in much water, to form a dilute aqueous solution of 4 × 128 g. hydrogen iodide, and 2 × 32 g. solid sulphur. Ostwald sometimes indicates the temperature by figures in brackets placed after the formulæ of the substances: thus, $\mathrm{H_2O}_{(0)} = \mathbf{H_2O}_{(0)} + 1440$ means that 1440 gram-units of heat are produced when 18 g. liquid water at 0° become 18 g. solid water at the same temperature.

Measurements of thermal values of chemical changes. The quantities of heat produced during chemical processes are measured by causing the processes to take place in vessels arranged so that the whole of the heat is used in raising the temperature of known masses of water, or of water and a solution the specific heat of which is known. When the process consists in a reaction between substances in aqueous solutions, the calorimeter employed usually consists of a vessel of platinum holding 500 to 1000 c.c. placed inside another vessel of silver, or thin sheet iron, with water between the two vessels. The reacting liquids are brought to the same temperature, and are then mixed in the platinum vessel, and the rise of temperature of the contents of this vessel is noted, any change in the temperature of the outside water being also measured. When the thermal value of a process of combustion is to be determined, the combustion is caused to proceed in a vessel, usually made of platinum, surrounded by a determinate quantity of water; if the products of combustion are gases, an apparatus is attached wherein these gases are absorbed, and thus the quantity of substance burnt is determined.[1]

To calculate the thermal value of a reaction, it is necessary to know the initial temperatures of the reacting bodies, the final temperatures of the products of reaction, the masses of the reacting substances, the specific heat of water, the specific heat of the liquid formed by the reaction if the reaction be one wherein a solution is produced, and the water-equivalent of the calorimeter. The water-equivalent of the calorimeter must be determined; it is equal to the number of unit-weights of water which would be raised to the same temperature as that to which the calorimeter and its accessories—thermometer, stirrer, &c.—are raised by the heat produced in the process. When dilute solutions of acids and alkalis, or similar compounds, react, the specific heat of the dilute salt-solutions produced may be taken as equal to the specific heat of the water they contain, without appreciable errors.

Let Q be the quantity of heat produced in a reaction between two solutions; let t be the initial temperature of one solution, t' the initial temperature of the other solution, and T the final temperature of the solution produced; further, let a be the calorimetric equivalent of one solution, *i.e.* mass × spec. heat, b the calorimetric equivalent of the other solution, and c the water-equivalent of the calorimeter; then

$$Q = (T - t)a + (T - t')(b + c).$$

In the cases of dilute aqueous solutions, a and b represent the masses of water in the solutions mixed. If a change occurs in the state of aggregation of some of the constituents of the reacting system, *e.g.* if liquid water is formed from gaseous hydrogen and oxygen, the quantity of heat which is produced or disappears in this change must be taken into account in the calculation of the thermal value of the reaction. If contraction or expansion occurs, without change of state, the thermal value of such contraction or expansion must be determined and allowed for.[2]

Heats of combustion, and of formation, of compounds. The heat of combustion of an element or compound is the thermal value of the reaction which takes place when that element or compound is completely oxidised to those masses of the product, or products, of oxidation which are represented by the formulæ of these products. Thus [H^2,O] = 68,360; [CO,O] = 67,960. In this DICTIONARY the quantities represented by formulæ are taken in grams.

---

[1] For references to descriptions of calorimetrical apparatus *v. References*, p. 268.

[2] For methods of calculating Q at one temperature when it is known at another temperature, *v. TA.* 1, 60-78.

The heat of formation of a compound is the thermal value of the reaction whereby the formula-weight of the compound is produced from the formula-weights of its constituents. Thus, the heat of formation of H$_2$SO$_4$ varies according to the constituents from which it is produced; we have the following statements: [SO^3,H^{2}O] = 21,320; [SO^2,O,H^{2}O] = 53,480; [SO^2,O^2,H^2] = 121,840; [S,O^3,H^{2}O] = 124,560; [S,O^4,H^2] = 192,920.

It is often practicable to measure heats of combustion directly; but in very many cases it is necessary to determine heats of formation by indirect methods. These indirect methods rest on the principle, deduced from the laws of energy, that the total change of energy, and therefore the total thermal change, which accompanies the passage of any system from a definite initial composition to a definite final composition is independent of the intermediate states. Suppose that a system changes from a certain arrangement or configuration A to another configuration B, and that x units of heat are produced in this change. Suppose also that the same initial system then passes from the state A to a new state a, from that to b, from that to c, and, lastly, from that to B, and that there are x' units of heat produced in the first of those intermediate changes, x'' units produced in the second, and x''' units in the third; then $x - (x' + x'' + x''')$ gives the thermal value of the change from the state c to the state B. If then the thermal value of a chemical process, whether the formation of a compound, or other process, cannot be determined by direct measurement, it may be determined if the process can be made a portion of a series of changes, the total thermal value of which is measurable, and the thermal values of all the portions of which are measurable with the exception of the value of that portion which is sought.

For instance, formic acid, CH$_2$O$_2$, cannot be directly produced from C, H, and O, and, therefore, the heat of formation of this acid cannot be determined by direct measurement; but C and H can be burnt to CO$_2$ and H$_2$O, and CH$_2$O$_2$ can also be burnt to CO$_2$ and H$_2$O; hence we can acquire the data needed for calculating the value of [C,H^2,O^2]. The data are these: [C,O^2] = 96,960; [H^2,O] = 68,360; sum = 165,320; [CH^{2}O^2,O] = 65,900. Now, suppose that the first stage of the combustion of C and H$_2$ consists in the formation of CH$_2$O$_2$, and that this is then burnt to CO$_2$ and H$_2$O, we should have the statement: [C,O^2] + [H^2,O] = [C,H^2,O^2] + [CH^{2}O^2,O] = 165,320. But [CH^{2}O^2,O] = 65,900; and also [C,O^2] + [H^2,O] − [CH^{2}O^2,O] = [C,H^2,O^2]. Hence [C,H^2,O^2] = 165,320 − 65,900 = 99,420.

Another example will show the application of the principle to a more complicated case. It is required to find the heat of formation of gaseous hydrogen bromide from gaseous H and Br, *i.e.* the thermal value of the reaction H + Br = HBr. To begin with: let [H,Br,Aq] = x, and let [H,Br] = x'; direct measurement gives [HBr,Aq] = 19,900. ∴ x − 19,900 = x' = heat of formation of HBr. Hence it is necessary to determine x.

Now, the thermal values of the neutralisation of HClAq and HBrAq respectively by KOHAq are found to be the same, *i.e.* [KOHAq,HClAq] = [KOHAq,HBrAq]. If these reactions are analysed, the first is seen to consist in (1) the splitting of HClAq into H and Cl in presence of water; (2) the separation of KOHAq into K, O, and H in presence of water; (3) the combination of K and Cl, in presence of water, to form KClAq; (4) the combination of H, H, and O, in presence of water, to form water; and the second is similar to this, only putting Br in place of Cl. These reactions may be stated in thermo-chemical notation thus:

(1) [KOHAq,HClAq] = − [K,O,H,Aq] − [H,Cl,Aq] + [K,Cl,Aq] + [H,H,O,Aq];
(2) [KOHAq,HBrAq] = − [K,O,H,Aq] − [H,Br,Aq] + [K,Br,Aq] + [H,H,O,Aq].

The first and fourth terms on the right side are the same, and the total thermal values are the same. Are the values of the second and third terms the same? To answer this question we pass Cl into KBrAq, forming KClAq and BrAq, and measure the thermal disturbance; we then analyse the reaction, and see what information it has afforded. These are the results:

[KBrAq,Cl] = 11,500,
i.e. − [K,Br,Aq] + [K,Cl,Aq] + [Br,Aq] = 11,500.

Now, [Br,Aq] − 500, by direct measurement, ∴ − [K,Br,Aq] + [K,Cl,Aq] 11,000, *i.e.* to form KCl, in solution, from K and Cl produces 11,000 units of heat more than to form KBr, in solution, from K and Br.

Now, turning back to equations (1) and (2) above, and remembering that the thermal values of these are the same, it is evident that, since 11,000 more heat-units are produced in forming KClAq than in forming KBrAq, each from its elements, 11,000 more heat-units must disappear in splitting up HCl, in presence of water, into H and Cl, in presence of water, than in similarly separating HBr into H and Br in presence of water; and therefore, since the heat energy required to decompose a stated mass of a compound is equal to the heat energy that is produced when the same mass of that compound is formed, 11,000 more heat-units will be produced in the formation of HClAq from H, Cl, and Aq than in the formation of HBrAq from H, Br, and Aq; or, stated in thermo-chemical notation: [H,Cl,Aq] − 11,000 = [H,Br,Aq]. Now [H,Cl,Aq] = 39,300 by direct measurement,

∴ [H,Br,Aq] = 39,300 − 11,000 = 28,300.

At the beginning of this calculation we had [H,Br,Aq] − 19,900 = [H,Br]. We can now substitute the value of [H,Br,Aq], and write [H,Br] = 28,300 − 19,900 = 8,400. That is to say, 8,400 gram-units of heat are produced when 81 g. gaseous hydrogen bromide are formed from 1 g. gaseous hydrogen and 80 g. gaseous bromine.

Exothermic and endothermic reactions. Chemical changes which are accompanied by production of heat are sometimes classed together as exothermic reactions, and are distinguished from changes accompanied by disappearance of heat, which changes are called endothermic reactions. The terms endothermic and exothermic are sometimes useful. It should not be forgotten that most chemical reactions consist of portions which are exothermic and portions which are endothermic. Substances which are formed with the disappearance of heat are generally more readily decomposed by the application of outside forces than substances which are formed with the production of heat.

Interpretation of thermo-chemical measurements. Thermo-chemical measurements aim at determining the quantities of heat which are produced or disappear during definite and defined chemical changes. But every chemical change is inextricably bound up with more or less extensive physical changes; hence some portion of the thermal value of a chemical occurrence is always due to a process which is not, strictly speaking, chemical. A purely chemical change is a change in the distributions, configurations, and motions of atoms. But in only some cases are we able to form clear conceptions as to the configurations and motions of atoms; therefore, even if it were possible always to disentangle the purely chemical from the accompanying physical parts of a change, we should still very frequently be unable to connect the thermal values of purely chemical processes, in a clear and definite way, with measurable changes in the distributions, configurations, and motions of atoms.

The heats of formation of HCl, HBr, and HI are said to be 22,000, 8,440, and −6,050 gram-units respectively. But these thermal values are not strictly comparable, because the first represents the heat produced in forming gaseous HCl from gaseous H and Cl; the second represents the heat produced in forming gaseous HBr from gaseous H and liquid Br, and the third represents the heat which disappears when gaseous HI is formed from gaseous H and solid I. In other words, more heat is used in the second change than in the first, and still more in the third than in the second, in accomplishing subsidiary physical changes. Steam is decomposed by chlorine, with formation of hydrogen chloride and oxygen. All the reacting substances are gases. This change, which is stated in formulæ as $2H_2O + 2Cl_2 = 4HCl + O_2$, when analysed thermo-chemically, is found to consist of four parts, thus: $[2H^2O,2Cl^2]$

$$= -2[H,H,O] - 2[Cl,Cl] + [O,O] + 4[H,Cl].$$

We measure the thermal value of this complete change, but we cannot at present separate the portions of the change and assign to each its proper thermal equivalent; hence we cannot give a complete explanation of the thermo-chemical measurement we have made.

Notwithstanding these difficulties, attempts have been made to generalise from thermo-chemical measurements to statements of universal applicability. The most widely known of such attempts is that which finds expression in Berthelot's '*law of maximum work*.'[1] This so-called law asserts that '*Every chemical change accomplished without the addition of energy from without tends to the formation of that body, or system of bodies, the production of which is accompanied by the development of the maximum quantity of heat.*' In another place Berthelot states the law more rigidly, thus: '*Every chemical change which can be accomplished without the aid of a preliminary action, or the addition of energy from without the system, necessarily occurs if it is accompanied by disengagement of heat.*'

The same generalisation was stated by Thomsen (*v. Th.* 1, 12–16) some years before it was enunciated by Berthelot. Thomsen's statement took this form: '*Every simple or complex reaction of a purely chemical kind is accompanied by production of heat.*' None of these statements is strictly applicable to actually occurring chemical changes, because we never have to deal with reactions of a purely chemical kind, but with reactions that are partly chemical and partly physical—that is, with reactions which consist in part in changes in the arrangement and motions of atoms, and partly in changes in the arrangement and motions of molecules. A consideration of the way in which the so-called law is applied, especially by Berthelot and his school, shows that it is taken to mean that measurements of the thermal values of various possible chemical changes enable us to predict which of these will occur. Thus, suppose we start with a system $A + B + C$, and suppose that from this may be formed $AB + C$, $AC + B$, or ABC; suppose also that x thermal units are produced in the first of these changes, x' thermal units in the second, and x'' thermal units in the third; finally, suppose that $x'' > x' > x$; then the law of maximum work is taken as asserting that the reaction $A + B + C = ABC$ will occur, and will occur to the complete, or almost complete, exclusion of the two other possible reactions.

It is easy to show that many reactions are known to occur which would be impossible were this 'law' a true generalisation. But it is better to treat the law as a deduction from the principles of energy, and to show that it is not a warrantable deduction.

The statements made by Thomsen and Berthelot are true only when an arbitrary separation is made of chemical changes into two parts, and one of these parts is alone called chemical. Every chemical change, however simple, consists of at least two parts, the first of which is the necessary antecedent of the second; the 'law of maximum work' ignores this duality, or, it might be more accurate to say, the law assumes that the second part of a chemical process may occur without the first. A process of chemical change may be compared to the flight of a stone from, and its return to, the surface of the earth. During the first part of this process there is a continual transference of kinetic energy from the moving stone to the surrounding medium and during the second part there is a continual transference from the medium to the stone, until the stone comes to rest, when its energy becomes a part of the total energy of the system earth *plus* stone. If the final resting-place of the stone is nearer the centre of the earth than the spot from which it was projected in its upward flight, then the stone contains less energy, relatively to surrounding systems, at the close of the transaction than at the beginning. On the other hand, if the starting-point is nearer the earth's centre than the final point of rest, then the transaction has resulted in a gain of energy to the stone. In both cases the second part of the transaction, that which occurs between the turning-point and the coming to rest of the stone, is attended with loss of energy to the stone; but this second part does not represent the complete transaction. The 'law of maximum work,' if applicable at all, is applicable only to the second part. And, moreover, this law ignores the fact that the stone, or chemical system, does not leave its initial resting-place of its own accord; the law assumes that no work need be done, no energy need be expended, in the passage of the stone, or chemical system, from its original position to that whereat the energy-relations between it and surrounding systems come within the cognisance of the law.

---

[1] *Mécanique Chimique*, i. xxix.

The 'law of maximum work' asserts a certain condition of equilibrium for a chemical system, for the law states that equilibrium results when that change has occurred which is attended with the maximum production of heat. But the true condition of equilibrium of a material system undergoing a reversible change is laid down in the statement that equilibrium results when the *entropy* of the system has attained the maximum value under the conditions which prevail.

Let Q = quantity of heat added to a body at constant temperature T, then $\frac{Q}{T}$ = gain of entropy to the body; let Q_1 = quantity of heat lost by a body at constant temperature T_1, then $\frac{Q_1}{T_1}$ = loss of entropy to the body. All chemical and physical changes which occur spontaneously increase the entropy of the system. This statement holds good for non-reversible changes; and as no actually occurring change is completely reversible, the statement holds for all changes.

Suppose that one of two bodies is hotter than the other and loses heat to the colder body; the hotter body at temperature T_1 loses heat Q, therefore its entropy is diminished by $\frac{Q}{T_1}$; the colder body at temperature T_2 gains heat Q, therefore its entropy is increased by $\frac{Q}{T_2}$; but as $T_1 > T_2$, it follows that $\frac{Q}{T_1} < \frac{Q}{T_2}$; in other words, the entropy of the system is increased by the passage of heat from the hotter to the colder body.

Now, a system is in equilibrium when its entropy has attained the maximum value possible under the conditions. But, inasmuch as entropy is measured by a quantity of heat divided by a temperature, it is only at the absolute zero of temperature that $dS = dQ$ (S = entropy, Q = quantity of heat); hence it is only at the absolute zero that thermal changes directly measure changes of entropy. When a chemical change is accompanied by the production of much heat, and the change occurs at a low temperature, the thermal change will roughly measure the change of entropy; therefore, if such a change be possible, it will occur. But if the quantity of heat produced in a chemical process is small, the change of entropy may be conditioned, to a large extent, by changes other than the thermal change. Indeed, in some cases, heat may disappear from the system, and yet the total change of entropy may be positive; in such cases, chemical change will occur with the disappearance of heat, because the decrease in the entropy of the system caused by the loss of heat will be more than balanced by the increase in the entropy caused by the changes of state which the system undergoes.

The general conception of chemical change which is given by applying the law of entropy is that of a system attaining equilibrium as the result of processes taking place in opposite directions. According to van't Hoff (*Dynamique Chimique*, 153), the directions of chemical processes which result in equilibrium vary with variations of temperature in such a way that the lower the temperature the more is equilibrium established with the production of heat, but the changes can take place wholly in one direction only at the absolute zero. The 'law of maximum work' would then hold good for the limiting case that the change should occur at −273°. As the temperatures at which most chemical changes occur are not very high, many chemical processes are accompanied by production of heat.

The 'law of maximum work' is not, then, a law of nature. But it is true that most chemical processes which occur without the expenditure of much energy from without, and which take place at moderate temperatures, are accompanied by the disengagement of heat. If it is known that a certain chemical change would be attended by the disappearance of much heat, we may conclude that this change will be difficult to accomplish; that it will be brought about only by the expenditure of a considerable quantity of energy, and that the most successful way of accomplishing the change will be to make it one part of a series of changes the sum of which is attended with the disengagement of heat.

Applications of thermo-chemical methods. The applications of thermo-chemical methods are many and varied. A few of the more important will be briefly dealt with here.

Neutralisation of acids and bases. In 1842 Hess stated the principle of the *thermo-neutrality* of salts in solutions (*P.* 52, 79). He said that when aqueous solutions of two normal salts are mixed the thermal disturbance is *nil*; in other words, that the thermal value of the reactions consisting in the exchange of the acids and bases is equal to zero. Hess supposed that the heats of neutralisation of acids were independent of the nature of the bases used. Andrews (*P.* 54, 208; 59, 428) thought that the heats of neutralisation were dependent only on the bases, and were independent of the nature of the acid employed. Favre a. Silbermann (*A. Ch.* [3] 34, 357; 36, 1; 37, 406) put the law of thermo-neutrality in its proper form by showing that the differences between the heats of neutralisation of any two bases by any acid have a constant value, and the differences between the heats of neutralisation of two acids by any base are constant. Let the composition of various salts be represented by the scheme:

$A+B$	$A'+B$	$A''+B$	$A'''+B$
$A+B'$	$A'+B'$	$A''+B'$	$A'''+B'$
$A+B''$	$A'+B''$	$A''+B''$	$A'''+B''$
$A+B'''$	$A'+B'''$	$A''+B'''$	$A'''+B'''$

And let $f(A+B)$, $f(A'+B)$, &c., represent the quantities of heat produced by the union of the acid A with the base B, the acid A′ with the base

B, &c. Then the law of thermo-neutrality asserts that

$$f(A+B)+f(A'+B')-f(A+B')-f(A'+B)=0$$
or $$f(A+B)-f(A+B')=f(A'+B)-f(A'+B')$$
and $$f(A+B)-f(A'+B)=f(A+B')-f(A'+B')$$

Exceptions have been found to this law, but these exceptions have all proved to be connected with some abnormality in the behaviour of the salts formed. The law may be stated by saying that, in the normal formation of a salt, in solution, by the reaction between an acid and a base, the acid contributes a definite portion of the total heat of neutralisation, independently of the nature of the base, and the base contributes a definite portion of the total heat of neutralisation, independently of the nature of the acid. If the statement is correct, then the heat of neutralisation of an acid, in solution, must be independent of the nature of the base, and the heat of neutralisation of a base, in solution, must be independent of the nature of the acid, unless there be some divergence from the normal condition of affairs. By the *heat of neutralisation* of an acid is meant the quantity of heat produced when an equivalent weight of the acid reacts with an equivalent weight of a base, both being in *dilute* aqueous solution. If A′ represents a formula-weight of a monobasic acid, A″ a formula-weight of a dibasic, and A‴ a formula-weight of a tribasic, acid; and if B represents a formula-weight of a mono-acid base; then the heats of neutralisation of these three acids are the thermal values of the reactions, [A′Aq,BAq] ; [$\frac{1}{2}$A″Aq,BAq] ; and [$\frac{1}{3}$A‴Aq,BAq]. Sometimes it is more convenient to take the thermal values of the reactions [A″Aq,2BAq] and [A‴Aq,3BAq] to represent the heats of neutralisation of the dibasic and tribasic acids respectively.

The following table, taken chiefly from Thomsen's results, shows that the heats of neutralisation of the strong acids are practically independent of the base, provided the base used is strong; the numbers all refer to reactions between dilute solutions of the acids and bases:—

Acid	NaOH	KOH	LiOH	TlOH	$\frac{1}{2}BaO_2H_2$	$\frac{1}{2}CaO_2H_2$	$\frac{1}{2}SrO_2H_2$	$\frac{1}{2}Pt(NH_3)_4(OH)_2$	$S(C_2H_5)_3OH$	$N(CH_3)_4OH$
HCl	13,300	13,300	13,300	13,300	13,300	13,300	13,300	13,600	13,700	13,600
HBr	13,300	13,300	—	—	—	—	—	—	—	—
HI	13,300	13,300	—	—	—	—	—	—	—	—
HNO_3	13,500	13,500	—	13,500	14,000	13,900	—	—	—	—
$HClO_3$	13,600	13,600	—	—	14,000	—	—	—	—	—
$HBrO_3$	13,600	13,600	—	—	—	—	—	—	—	—
HIO_3	13,600	13,600	—	—	—	—	—	—	—	—
$HClO_4$	14,000	14,000	—	—	—	—	—	—	—	—
$\frac{1}{2}H_2S_2O_6$	13,500	—	—	—	13,800	—	—	—	—	—
$\frac{1}{2}H_2PtCl_6$	13,600	—	—	—	—	—	—	—	—	—
$H.C_6H_5.SO_3$	13,500	—	—	—	13,600	—	—	—	—	—

If concentrated solutions are employed, the heats of neutralisation, even of the strong acids, show considerable differences with different bases. If the salt which is formed by neutralising an acid by a base is allowed to precipitate, then the apparent heat of neutralisation as thus determined is not the true heat of neutralisation (*v. Th.* 1, 440). The following numbers represent the heats of neutralisation of two strong acids by weak bases; these numbers differ from one another, and also from the values given in the preceding tables in which strong acids and strong bases only were included:

Acid	NH_3	NMe_3	NH_2OH
HCl	12,200	8,700	9,200
HNO_3	12,300		

When weak acids neutralise strong bases, the thermal values differ from those obtained for strong acids; and when weak acids neutralise weak bases the reactions have different values from any of the preceding cases. The following numbers illustrate this:

Acid	NaOH (strong bases)	$\frac{1}{2}BaO_2H_2$ (strong bases)	NH_3 weak base
Weak { CO_2Aq	10,100	10,900	8,400
Weak { H_2S	7,700	7,800	6,200

The electrolytic dissociation hypothesis gives an explanation of the facts concerning the thermo-chemical reactions between acids and bases. According to this hypothesis, a dilute aqueous solution of a salt contains the ions of the salt each with its electric charge; the salt is dissociated into its ions; when two dilute salt solutions are mixed, the ions remain as they were, there is no change, and therefore heat is neither produced nor consumed. The law of thermo-neutrality holds. The hypothesis looks on a dilute aqueous solution of a strong acid, or a strong base, as containing the ions of the acid or the ions of the base; when the solutions of the strong acid and strong base are mixed, a salt is not formed in the solution, because in dilute solutions salts are wholly dissociated, but water is formed by the union of the ion H of the acid with the ion OH of the base. Thus, the composition of dilute solutions of HCl and NaOH, before and after mixing, are represented by the hypothesis as follows:

$$\underbrace{\overset{+}{Na}+\overset{-}{OH}+\overset{+}{H}+\overset{-}{Cl}}_{\text{before mixing}} \text{ and } \underbrace{\overset{+}{Na}+\overset{-}{Cl}+HOH.}_{\text{after mixing}}$$

Or, generally, if M represent the positive ion of a strong base, and A the negative ion of a strong acid; we have the composition of the dilute aqueous solutions, before and after mixing, represented by the two schemes:

$$\underbrace{\overset{+}{M}+\overset{-}{OH}+\overset{+}{H}+\overset{-}{A}}_{\text{before mixing}} \text{ and } \underbrace{\overset{+}{M}+\overset{-}{A}+HOH}_{\text{after mixing}}$$

Hence, as the only process wherein heat can be produced consists in all cases in the union of H with OH, the quantity of heat produced is always the same.

The hypothesis asserts that HOH is produced because water is a non-dissociable, or nearly a non-dissociable, compound; pure water is, approximately, a non-electrolyte.

But when a weak acid is mixed, in dilute aqueous solution, with a strong base, or when dilute solutions of a weak acid and a weak base are mixed, the processes are more complex; for, according to the hypothesis, only a portion of the weak acid is dissociated into ions, and only a portion of the base is dissociated if the base is weak. In such cases the state of matters, before and after mixing, would be represented thus (supposing both acid and base to be weak)—

$$\underbrace{HA + \overset{+}{H} + \overset{-}{A} + MOH + \overset{+}{M} + \overset{-}{OH}}_{\text{before mixing}}$$

$$\text{and}\quad \underbrace{HA + MOH + \overset{+}{M} + \overset{-}{A} + HOH}_{\text{after mixing}} \quad . \quad .$$

But the process does not necessarily stop here; there is a striving towards the formation of the comparatively non-electrolytic compound HOH, therefore more of the acid and more of the base become dissociated, so that we have, as a final condition, less or more of the acid *HA*, and less or more of the base *MOH*, *remaining in the* solution. The dissociation of the acid and the base, when these are mixed, is accompanied by a thermal change; and as the degree to which this dissociation proceeds depends on the nature of the acid and the base, the values of the heats of neutralisation of weak acids and weak bases differ one from another (*cf.* ELECTRICAL METHODS, p. 189 in this vol.).

If this treatment of the heats of neutralisation of acids and bases is accepted, it is evident that the thermal values of the neutralisations of acids by a base do not necessarily measure the affinities of these acids for that base. If the acids were all equally dissociated in solution, they would all be equally strong—or their affinities would be equal—and their heats of neutralisation would be equal. The statement Q = about 13,500 + A + B expresses the heat of neutralisation of any acid by any base in dilute aqueous solution. A represents the heat of dissociation of the acid, and B is the heat of dissociation of the base, into their ions; A and B may be positive or negative at any specified temperature. Under the conditions of the experiment only a portion of the acid, or of the base, may be dissociated; therefore the observed heat of neutralisation cannot measure the affinity of the acid for the base. But at the same time, it is evident that there is a connection between the heats of neutralisation and the affinities of acids and bases. On the one hand, measurements of the thermal values of the reactions between acids and bases enable conclusions to be drawn as to the distribution of two acids between one base, or two bases between one acid, and such measurements therefore lead to determinations of the affinities of acids and bases (*v. infra*); on the other hand, although the affinity of an acid for a base probably consists in a striving towards electrical equilibrium among the ions, yet, as electrical and thermal phenomena are closely connected, measurements of the heats of dissociation of acids and bases, in aqueous solutions, must help us to understand the relative affinities of acids and bases, to classify acids and bases in accordance with their affinities, and to connect the affinities of these substances with their constitution (*cf.* ELECTRICAL METHODS, especially pp. 208 and 209).

Monobasic and polybasic acids. When an equivalent of a monobasic acid is added to an equivalent of a base, both in dilute solutions, a certain quantity of heat is produced, and there is no further thermal disturbance on adding more of the acid to the neutral solution; but heat is either produced or disappears when a polybasic acid is added to a solution of the same acid which has been neutralised by an equivalent quantity of a base. This behaviour enables a thermo-chemical distinction to be drawn between monobasic and polybasic acids (*cf.* ACIDS, BASICITY OF, vol. i. p. 51).

Distribution of an acid between two bases. Thomsen found the following data:

$$[H^2SO^4Aq, 2NaOHAq] = 31{,}380;$$
$$[2HNO^3Aq, 2NaOHAq] = 27{,}230;$$
$$[Na^2SO^4Aq, 2HNO_3Aq] = -3{,}500.$$

Now, supposing that the reaction of equivalent quantities of Na_2SO_4 and HNO_3, in dilute solution, produced $NaNO_3$ and H_2SO_4, and these *compounds only, this reaction would be attended* by the disappearance of 31,380 − 27,230 = 4,150 thermal units; but as only 3,500 thermal units disappear in the reaction, it is evident that some change has occurred wherein heat has been produced, or that the whole of the Na_2SO_4 has not been changed to $NaNO_3$ by the reaction of the equivalent quantity of HNO_3. If we suppose that the discrepancy in the quantity of heat consumed is due to the partial decomposition of the Na_2SO_4 by the HNO_3; in other words, if we suppose that when equivalent quantities of Na_2SO_4 and HNO_3 react in solution, some of the base remains united with the H_2SO_4 and some goes into combination with the HNO_3, and that no other reaction occurs, it is easy to calculate the distribution of the base between the two acids. For it is evident that, on this supposition, $\frac{3500}{4150} = {\cdot}845$ of the quantity of Na_2SO_4 present has been decomposed. Thomsen found that H_2SO_4 reacts with Na_2SO_4 to form $NaHSO_4$, with disappearance of heat. He also found that this reaction is expressed thermo-chemically by the statement $[nH^2SO^4Aq, Na^2SO^4Aq]$

$$= 31{,}380 - \frac{n}{n + {\cdot}8}\, 3{,}300.$$

These data give a means for calculating the distribution of the base between the two acids. The complete reaction between equivalent quantities of Na_2SO_4 and HNO_3 will consist of three parts: (1) the decomposition of *a* equivalents of Na_2SO_4, attended with the disappearance of *a* . 31,380 thermal units; (2) the formation of *a* equivalents of $NaNO_3$, attended with the production of *a* . 27,230 units of heat; (3) the reaction of *a* equivalents of H_2SO_4 with $1-a$ equivalents of Na_2SO_4, attended with the disappearance of

$$1-a\,\frac{\dfrac{a}{1-a}}{\dfrac{a}{1-a}+{\cdot}8}\,3{,}300 \text{ units of heat.}$$

The complete thermo-chemical change may be stated thus:

$$[Na^2SO^4Aq, 2HNO^3Aq] = -3{,}500$$

$$= a(27{,}230 - 31{,}380) - (1-a)\,\frac{\dfrac{a}{1-a}}{\dfrac{a}{1-a} + \cdot 8}\,3{,}300.$$

Thomsen found that if a is taken as ⅔, the number −3550 is obtained, which is almost identical with the observed value. Hence Thomsen concluded that ⅔ of the base, NaOH, went to the nitric acid, and ⅓ to the sulphuric acid; or, that the affinity of nitric acid for soda (Thomsen used the term *avidity*) is twice as great as the affinity of sulphuric acid for the same base.

The relative affinities of various acids for different bases have been measured by Thomsen by this method (*v.* Affinity, vol. i. pp. 74–75).

Allotropy and isomerism. The generally accepted views regarding the allotropy of elements and the isomerism of compounds would lead us to expect that the formation of one allotropic form of an element from another form, or the formation of one isomeride from another, should be accompanied by changes of energy, and, therefore, probably by the production or disappearance of heat. This expectation is confirmed by thermo-chemical measurements. The following tables present some typical data:—

Combustion of allotropic forms of sulphur, phosphorus, and carbon.

$[S,O^2]$	to form	gaseous SO_2
71,220	for	S crystallised from CS_2
71,720	„	rhombic S
72,300	„	native opaque S

$[P^2,O^5]$	to form	solid P_2O_5
369,900	for	ordinary P
362,800	„	red P

$[C,O^2]$	to form	gaseous CO_2
96,900	for	amorphous C
93,200	„	diamond

Combustion of isomeric carbon compounds.

$[C^6H^6,O^{15}]$	to form	$6CO_2 + 3H_2O$
787,900	for	benzene
883,200	„	dipropargyl

$[C^2H^6O,O^6]$	to form	$2CO_2 + 3H_2O$
330,400	for	ethylic alcohol
344,200	„	methylic ether

$[C^3H^6O,O^8]$	to form	$3CO_2 + 3H_2O$
442,600	for	allyl alcohol
424,000	„	acetone
420,000	„	propaldehyde

These values, and many more might be given, show that the quantity of heat produced in the change from the combination of a certain number of atoms to certain other combinations of these atoms is dependent, in part, on the arrangement of the atoms in the initial combination. Isomeric molecules differ in the arrangements of their parts; and they also differ in the quantities of energy which are associated with the different atomic arrangements.

The attempts which have been made, chiefly by Thomsen (*v. Th.* vol. iv.), to connect in a definite way the thermal values of the combustion and formation of carbon compounds with the constitutions of these compounds have not led, as yet, to any very satisfactory results (*v.* also Armstrong's criticism of some of Thomsen's conclusions; *P. M.* Feb. 1887. 73).

Dissociation.—This very important branch of the subject is fully discussed in the article Dissociation in vol. ii. pp. 385–410.

XII. VAPOUR-PRESSURES OF SOLUTIONS, METHODS BASED ON, *v.* Molecular weights, vol. iii. p. 420; Electrical methods, this vol. p. 185; and Solutions, this vol.

XIII. VISCOSITY OF LIQUIDS. A perfect fluid, if such existed, would offer no resistance to a change of shape, and if its parts were set in motion relatively to each other by the action of any forces, the work done would be exactly equal to the kinetic energy produced. Moreover, this energy of motion would continue unchanged in amount if the fluid were then left to itself, and would not die away by being converted into heat as is the case with every known fluid. The property which causes this subsidence of relative motion is called viscosity. In consequence of the existence of viscosity a continual expenditure of energy is required to maintain the parts of a fluid in a state of steady motion relatively to each other, just as the existence of friction makes it necessary to apply a constant force to a body to keep it moving uniformly over another. From this resemblance in the two cases the viscosity of a substance is often called its internal friction.

Imagine a layer of a liquid one cm. thick, contained between two flat plates, one of which is at rest and the other is moving parallel to the first. The liquid in contact with the plate which is at rest is at rest also, and the successive layers have velocities which increase uniformly as we go towards the moving plate, so that the liquid is being sheared, and this requires a continual supply of work; which is proportional to the area and velocity of the moving plate. If this velocity is one cm. per second, the coefficient of viscosity is defined as the tangential force which must be applied per sq. cm. to the moving plate to maintain the motion, or if the relative velocity of the two surfaces is v, and their distance apart is l, the tangential force T per unit area required to maintain the motion is given by $\mathrm{T} = \eta \frac{v}{l}$ where η is the coefficient of viscosity.

From this definition it can be proved that if a circular plate or other solid of revolution be set vibrating about its axis of figure in a liquid, the amplitudes of successive vibrations will bear a constant ratio to each other, and the experimental verification of this is the best proof we have of the proportionality of the viscous forces to the relative velocity of the parts of the fluid.

The coefficient of viscosity is regarded by Maxwell (*P. M.* [4] 35, 133) as being the product of two factors, a coefficient of elasticity and a time of relaxation. If between the parallel plates spoken of above we have an elastic solid without viscosity, instead of a liquid, the result of moving one of the plates parallel to the other will be to distort the solid, and give rise to a force or stress tending to restore it to its original shape, and this force will be proportional to the amount of distortion and to the coefficient of rigidity of the body. Now, if the body is a viscous substance like pitch, the stress will soon die away, even though the surfaces be held in the new position, the molecules rearranging themselves so that this position becomes one of equilibrium. The time required for this to take place is what Maxwell called the time of relaxation. For solids it may be very large, extending to several hours or even days, but for ordinary liquids it is a small fraction of a second, while for a gas, such as air, Maxwell estimated it at the fifty thousand millionth of a second. The rate at which this internal stress is disappearing at any moment is proportional to the strain at that moment. If the upper surface is moved uniformly, relatively to the lower one, the strain will never disappear entirely, for, although the rearrangement of the molecules is continually going on andthe substance is tending towards its equilibrium state, the strain is being continually set up again by the relative motion of the two surfaces we are considering, and the body will soon get into a steady state in which the rate whereat the strain is being produced is equal to the rate whereat it is dying away. The stress produced by this constant strain is the tangential force required to maintain the motion, and Maxwell proved that this stress is proportional to the coefficient of rigidity of the substance and to the time of relaxation.

For the determination of coefficients of viscosity, Coulomb and others allowed some solid of revolution, such as a circular plate or a sphere immersed in the fluid, to vibrate about its axis of figure, and observed the ratios of the amplitudes of consecutive vibrations, from which the coefficient can be calculated. O. E. Meyer (*W.* 43, 1) modified the method by hanging a flat cylindrical box by a bifilar suspension, filling it with liquid, and observing the rate at which the vibrations died away. This method has been used by Mützel (*W.* 43, 15), and is capable of considerable accuracy. For absolute measurements it has some advantages in the fact that the lengths to be measured are not very small; but in most cases only relative values are required, and for obtaining these the transpiration method described below is preferable, as it is more readily applied, requires a smaller quantity of material, and lends itself better to accurate adjustment of temperature.

In the common form of the experiment the liquid is caused to flow through a capillary tube in consequence of a constant difference of pressure, P, between the ends, and the time, t, is observed which is required for a volume, v, to flow through the tube; then the coefficient of viscosity, η, is given by the equation $\eta = \frac{\pi}{8} \frac{\mathrm{P}r^4 t}{lv}$, where r is the radius and l is the length of the tube. Hence the coefficients for two liquids will be in the ratio of the times required for the outflow of the same volume with the same difference of pressure. If the liquid flows through the tube in consequence of its own weight, P will be proportional to its specific gravity, and the coefficients of viscosity will be proportional to the product of specific gravity and time of flow.

The formula given above assumes that the work done by the pressure is entirely converted into heat inside the tube, or, in other words, that the liquid flows out without any appreciable kinetic energy. If the tube is very long and narrow this may be taken to be the case, but generally a small correction has to be applied for the energy of the issuing fluid. The form of this correction is doubtful. Hagenbach (*P.* 109, 385) has given a formula which has been largely used, but Wilberforce (*P. M.* 1891. 407) has pointed out an error in his assumptions which makes the correction probably too small.

The coefficient of viscosity falls off very rapidly with rise of temperature, the average rate of fall for water between 0° and 10° being nearly 3 p.c. per degree, which shows the necessity for very accurate adjustment of the temperature during an experiment.

Using Maxwell's conception of the nature of viscosity, and making certain assumptions as to the way in which the rigidity and the time of relaxation vary with the temperature, Graetz (*W.* 24, 25) deduced the formula $\eta = \mathrm{A} \frac{t_0 - t}{t - t_1}$, where t_1 is some low temperature at which η is infinite, and t_0 is the critical temperature. The formula expresses the facts very well over a moderate range, but, as we might as reasonably assume the connection between η and t as between the time of relaxation and t, it can only be regarded as empirical.

Extensive observations of the viscosity-coefficients of organic liquids have been made by Graham (*T.* 1861), Rellstab (*Inaug. Diss.* Bonn, 1868), Guerout (*C. R.* 81, 1025; 83, 1291), Pribram a. Handl (*Sitz. W.* 1878 and 1879), and Gartenmeister (*Z. P. C.* 6, 524); but few laws have been observed beyond qualitative relations applicable to small classes of compounds. In general the viscosity increases with the molecular weight, but formic acid is an exception, as it is more viscous than acetic acid. Isomeric esters have nearly the same viscosities, that with the higher alcohol radicle having the greater. Normal compounds are generally more viscous than the corresponding iso- compounds, but the propyl halogen compounds, and a few others, form exceptions. At high temperatures these differences are less marked than at lower ones, rise of temperature tending to efface the distinction between normal and iso- compounds. Pribram a. Handl endeavoured to find the conditions of temperature under which the results are comparable by determining the coefficients of viscosity of a number of liquids at various temperatures up to 50°. Taking the series PrCl, EtBr, PrBr, EtI, and PrI, they plotted the curve connecting viscosity with molecular weight, and found that while at the lower temperatures it was distinctly curved it got gradually flatter with rise of temperature, till at 50° it was almost a straight line, showing that at this temperature the increase of viscosity is proportional to the increase of molecular weight, whether this be due to the introduction of CH_2 or of a halogen.

Though sulphuric acid is much more viscous than water, the first effect of adding water to it is, as Graham showed, to increase its viscosity, and this continues till 18 p.c. of water has been added, when a maximum is reached, and further addition of water causes a rapid diminution of viscosity. The mixture with maximum viscosity corresponds to the proportions given by the formula $H_2SO_4.H_2O$, and there is a maximum in the electrical resistance near the same point. Similar relations are shown by nitric and acetic acids. For mixtures of alcohol and water Graham showed that the particular proportion of the constituents which gives the greatest contraction has maximum viscosity, and Traube (*B.* 19, 871) showed further that aqueous solutions of most alcohols and acids of the fatty series have maxima which occur at different concentrations according to temperature.

Arrhenius (*Z. P. C.* 1, 285) has investigated the relation between the concentration of a solution and its viscosity; he finds that for indifferent substances the exponential formula $\eta = A^{1-x}B^x$ expresses the results, where η is the viscosity, x the proportion by volume of the dissolved substance, and $1-x$ that of the solvent, so that A is the viscosity of the pure solvent, and B is a constant for the dissolved substance which is independent of the concentration up to about 10 p.c. As the solvent is usually water, and its viscosity is taken as the unit in comparative measurements, the formula can be written in the form $\eta = B^x$. In every case investigated by Arrhenius B proved to be greater than unity, showing that the viscosity of water is increased by the addition of a small quantity of an indifferent substance. The same is generally true of salts, but not quite invariably so. A viscous fluid like glycerin has less effect than ether has; there seems, in fact, to be no relation between the value of B and the viscosity of the dissolved substance alone.

The latest and most comprehensive determinations of the viscosities of salt solutions are by Reyher (*Z. P. C.* 2, 744), Wagner (*Z. P. C.* 5, 31), and Lauenstein (*Z. P. C.* 9, 417). The formula of Arrhenius in the form $\eta = A^x$, where x is now the number of gram-molecules in a litre of solution, or A is the viscosity of a normal solution, is found to hold moderately well, but for many salts of acids of the aromatic series it shows divergences if the strengths of the solutions are greater than half normal.

Wagner worked with sulphates, nitrates, and chlorides of metals, and found that the viscosities of solutions of equivalent quantities of the various salts are additive quantities, the part which the base or the acid contributes being approximately constant. A further relation is shown by tabulating the viscosities of normal solutions of the chlorides arranged according to the periodic law, when the coefficients are found to diminish in any group as the molecular weight increases. From this arrangement it would seem that copper and manganese should be put in the eighth group, for their coefficients are almost exactly equal to those of nickel and cobalt.

Reyher determined the viscosities of a number of acids and their sodium salts, and found they could be divided into two classes. The strong mineral acids have viscosities about 3 p.c. less than those of the sodium salts, while the weaker mineral acids and organic acids have coefficients from 20 to 30 p.c. less.

Lauenstein has found the viscosity-coefficients of solutions of the sodium salts of many organic acids. In the fatty series he found that substitution of CH_3 for H increases the viscosity, while the replacement of H by COOH or OH diminishes it. The change from succinic to maleic acid diminishes the viscosity, but if we remove two more atoms of hydrogen, giving acetylene dicarboxylic acid, we get a large increase.

In the aromatic series the results are less regular. Introduction of a carboxyl group into the ring still diminishes the viscosity, and this diminution is greater in the para- position than in the meta-, and greater in the meta- than in the ortho-; thus the viscosity diminishes regularly in the series shown by the formulæ at the top of p. 271.

According to the usual theory, the electricity which constitutes the current in an electrolyte is carried by charged ions, and it might be expected that the conductivity would be greater the more easily these ions were able to move along under the influence of the electromotive force—that is to say, the less the frictional resistance they had to overcome. On this account Wiedemann thought there would prove to be a connection between the viscosities and conductivities of solutions. Some experiments which he made seemed to point to the conductivity being inversely proportional to the viscosity, but though this was found at a later time to hold only in a few special cases, it has been shown that there is

$$C_6H_5.COONa,\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\COONa\end{smallmatrix}1{:}2,\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\COONa\end{smallmatrix}1{:}3,\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\COONa\end{smallmatrix}1{:}4.$$

With other replacing groups we have the following series, each being arranged in order of diminishing viscosity: —

$$1{:}2\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\NO_2\end{smallmatrix},\ 1{:}3\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\NO_2\end{smallmatrix},\ C_6H_5COONa,\ 1{:}4\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\NO_2\end{smallmatrix}$$

$$1{:}4\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\OH\end{smallmatrix},\ C_6H_5COONa,\ 1{:}3\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\OH\end{smallmatrix},\ 1{:}2\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\OH\end{smallmatrix}.$$

$$1{:}2\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\CH_3\end{smallmatrix},\ 1{:}4\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\OH\end{smallmatrix},\ C_6H_5.COONa,\ 1{:}3\ C_6H_4\Big\langle\begin{smallmatrix}COONa\\OH\end{smallmatrix}.$$

undoubtedly a close connection between the two properties.

This connection is shown very clearly by the work of Grotrian (*P.* 157, 130, 237; 160, 238), who determined the proportional rate of change with temperature of the viscosity and conductivity of salt solutions for various concentrations — that is, he calculated from his observations the values of $\frac{1}{f}\frac{df}{dt}$ and $\frac{1}{k}\frac{dk}{dt}$, where f is the coefficient of viscosity and k is the electrical conductivity, and found that though not equal they always vary in the same way with the concentration. If curves be drawn with the values of these coefficients at a fixed temperature for ordinates, and the concentrations for abscissæ, W. N. Shaw (*Camb. Phil. Proc.* 7, 21) has shown that the two curves run almost exactly parallel, any peculiarities in the shape of one being repeated in the other.

That the conductivity is not dependent on the viscosity alone is shown by the fact that if we add to an electrolyte such quantities of different non-conductors, as alcohol, sugar, glycerin, &c., as increase the viscosity by the same amount, the conductivity will generally be affected differently by the different substances. Arrhenius (*Z. P. C.* 9, 495) has investigated this effect at some length. He finds that the conductivity can be expressed by the equation: $l=l_0\left(1-\frac{\alpha}{2}x\right)^2$, where l_0 is the conductivity of the electrolyte alone, and l that which it has when x p.c. of the water is replaced by a non-conductor. Thus α may be taken as defining the change in the conductivity. The change in the viscosity of the electrolyte on the addition of 1 p.c. of non-conductor is the same as the change would be with water alone, and is hence equal to $A-1$, where A is the constant of the formula $\mu=A^x$.

On tabulating the values of 1000α and $1000\,(A-1)$ for a number of different salt solutions and non-conductors, it appears that the equation, $1000\,\alpha=c+1000\,c'(A-1)$ holds as a first approximation, and the electrolytes fall into four classes, for the members of any one of which the constants c and c' are the same. These classes are:

(1) Solutions of strong acids and bases;
(2) Solutions of salts of the type KCl;
(3) „ „ „ K_2SO_4;
(4) „ „ „ $BaCl_2$.

Arrhenius considers the relation not to be exact, but thinks it should include a term depending on the degree of dissociation, which can be neglected only in the cases of the more completely dissociated salts. J. W. C.

XIV. VOLUME-CHANGES, METHODS BASED ON, *v.* VOLUMES, SPECIFIC; this vol.

PHYSODIN $C_{10}H_{10}O_7$. [125°]. Extracted by ether from the dried lichen *Parmelia physodes* (or *Ceratophylla*) and crystallised from alcohol (Gerding, *N. Br. Arch.* 87, 1). Mass of minute prisms, insol. water. Forms a yellow solution in KOHAq.

PHYSOSTIGMINE *v.* ESERINE.

PHYTO-ALBUMOSES *v.* PROTEÏDS.

PHYTOLACCIC ACID. Occurs as K salt in the Poke Berry, the fruit of *Phytolacca decandra* (Terreil, *C. R.* 91, 856; *cf.* Claesson, *Ph.* [3] 10, 566). Extracted by dilute alcohol. Yellowish-brown resin.

PHYTOSTERIN *v.* vol. ii. p. 149.

PHYTO-VITELLIN *v.* PROTEÏDS.

PIAZTHIOLE $C_6H_4\Big\langle\begin{smallmatrix}N\\N\end{smallmatrix}\Big\rangle S$. [44°]. (206°). Formed by heating *o*-phenylene-diamine with aqueous SO_2 at 190° (Hinsberg, *B.* 22, 2899). Colourless crystals, sl. sol. hot water. Feeble base. Reduced by tin and HCl to *o*-phenylene-diamine.

Reference.—METHYL-PIAZTHIOLE.

PICENE $C_{22}H_{14}$. [345° cor.]. (520°). V.D. 9·8 (obs.). Occurs in the highest boiling portions of brown-coal tar (Burg, *B.* 13, 1884), and in the residues of Californian petroleum (Graebe a. Walter, *B.* 14, 175). Appears also to be formed by the action of ethylene bromide and $AlCl_3$ on naphthalene (Lespeau, *Bl.* [3] 6, 238). White plates with blue fluorescence, insol. alcohol and ether, sol. boiling solvent naphtha (150°–170°). On oxidation with CrO_3 it yields picoquinone $C_{22}H_{12}O_2$, which crystallises from HOAc as a dark orange-red powder, sublimes in red needles, and forms a green solution in pure H_2SO_4.

Di-bromo-picene $C_{12}H_{12}Br_2$. [206°]. Needles. (from xylene), insol. alcohol.

Picene hydrides $C_{22}H_{34}$ (over 360°) and $C_{22}H_{38}$ [175°] (over 360°) are got by heating picene with HIAq and red P at 250° (Liebermann a. Spiegel, *B.* 22, 781). $C_{22}H_{34}$ is liquid.

PICHURIN OIL contains the glyceryl ether of lauric acid (Sthamer, *A.* 53, 390).

PICOLINE *v.* METHYL-PYRIDINE.

PICOLINIC ACID *v.* PYRIDINE CARBOXYLIC ACID.

Dipicolinic acid *v.* PYRIDINE DICARBOXYLIC ACID.

DIPICOLYL *v.* DI-METHYL-DIPYRIDYL.

PICRACONITINE *v.* ACONITE ALKALOIDS.

PICRAMIC ACID *v.* DI-NITRO-AMIDO-PHENOL.

PICRAMIDE *v.* TRI-NITRO-ANILINE.

PICRASMIN $C_{35}H_{46}O_{10}$. [204°]. A bitter substance which, together with $C_{36}H_{48}O_{10}$ [209°–

212°], may be extracted by dilute alcohol from *Picræna excelsa* (Massute, *Ar. Ph.* [3] 28, 147; *C. J.* 58, 791). HClAq converts it into picrasmic acid $C_{31}H_{40}O_{6}(CO_2H)_2$, while fuming HIAq displaces three methyls.

PICRIC ACID *v.* Tri-nitro-phenol.

PICRO-ACONITINE *v.* Aconite alkaloids.

PICROCROCIN $C_{38}H_{66}O_{17}$. [75°]. Obtained by extracting saffron with ether (Kayser, *B.* 17, 2233). Colourless prisms. V. sol. water and alcohol, sl. sol. ether. Bitter taste. By heating with baryta-water or with dilute acids it is split up into crocose and the ethereal-oil of saffron $C_{10}H_{16}$.

PICROERYTHRIN *v.* Erythrite.

PICROLICHENIN $C_{12}H_{20}O_6$. [100°] (A.). S.G. 1·176. Extracted by alcohol from the lichen *Variolaria amara* (Alms, *A.* 1, 61; Vogel, *J.* 1857, 515). Trimetric octahedra, sl. sol. hot water, v. sol. alcohol and ether. Tastes very bitter. Its alkaline solutions turn red in air.

PICROROCCELLIN $C_{27}H_{39}N_3O_5$. [194°]. Occurs in a variety of the lichen *Roccella fuciformis* (Stenhouse a. Groves, *A.* 185, 14). Prisms, insol. water, m. sol. boiling alcohol, sl. sol. ether. Yields benzoic acid when oxidised by chromic acid mixture. Converted by boiling with HOAc and HCl into xanthoroccellin $C_{21}H_{18}N_2O_2$, which crystallises from alcohol in yellow needles [183°]. Boiling dilute (1½ p.c.) NaOHAq converts picroroccellin into $C_{21}H_{23}N_2O_3$ crystallising from alcohol in prisms [154°].

PICROSCLEROTIN. Occurs in ergot of rye (Dragendorff, *C. C.* 1878, 125, 141; Blumberg, *Ph.* [3] 9, 23, 66, 147). Dissolved in acids and is reppd. by ammonia. It is an active poison with bitter taste. *V.* Ergotinine.

PICROTOXIN $C_{30}H_{34}O_{13}$ (P. a. O.; S.); $C_{15}H_{16}O_6$ (B. a. K.). Occurs in Cocculus Indicus, the seeds of *Menispermum cocculus* (Boullay, *A. Ch.* [1] 30, 209; Casaseca, *A. Ch.* [2] 30, 307; Oppermann, *Mag. Pharm.* 35, 233; Pelletier a. Couerbe, *A. Ch.* [2] 54, 181; Liebig, *A.* 10, 203; Regnault, *A. Ch.* [2] 68, 160; Barth, *J. pr.* [1] 91, 155; Paterno a. Oglialoro, *G.* 6, 521; 7, 193). It is accompanied by anamirtin and picrotin (Barth a. Kretschy, *M.* 1, 99, 2,796).

Preparation.—1. The grains are exhausted with boiling alcohol, the extract evaporated, and the residue boiled with water. The aqueous solution is ppd. by lead acetate and the filtrate, freed from lead by H_2S, evaporated. The residue is crystallised from benzene and water successively (B. a. K.).—2. The powdered seeds are boiled with water, the filtrate treated with lead acetate and H_2S successively, and evaporated to crystallisation. The product is recrystallised from water and alcohol successively (Schmidt, *A.* 222, 313).

Properties.—Colourless needles, v. sl. sol. cold water, sl. sol. ether and chloroform, v. sol. alcohol. Very poisonous and very bitter. Sol. alkalis. Reduces Fehling's solution and ammoniacal $AgNO_3$.

Reactions.—1. When boiled with benzene for some time it is split up into picrotin and picrotoxinin (Schmidt). Probably the picrotoxin employed was a mixture of these two bodies.—2. HCl passed into an ethereal solution forms picrotoxide.—3. Cold AcCl also forms picrotoxide, but on boiling it yields a crystalline acetyl derivative [185°].—4. NaOAc and Ac_2O form $C_{19}H_{22}O_9$ [227°].

Picrotoxinin $C_{15}H_{16}O_6$ aq. [201°]. S. ·14 at 15°; S. (benzene) ·34 at 21°. Obtained from picrotoxin by treatment with benzene, $CHCl_3$, HCl, or AcCl. It constitutes about 30 p.c. of crude picrotoxin (Barth a. Kretschy). Colourless needles or plates. Very bitter and very poisonous. V. sol. hot water. Colours H_2SO_4 orange-red. Mixed with dry KNO_3 (3 pts.), moistened with H_2SO_4, and saturated with conc. NaOHAq it gives a red colour (Langley, *Am. S.* [2] 34, 109). After heating with milk of magnesia, the cold filtrate is coloured red by $FeCl_3$, the colour being destroyed by HCl. Bromine forms $C_{15}H_{15}BrO_6$ [250°-255°]. BzCl gives a crystalline compound (not the benzoyl derivative) [238°].

Picrotoxide $(C_{15}H_{16}O_6)x$. [above 310°]. Formed by the action of AcCl on picrotoxin, and by passing HCl into its ethereal solution (P. a. O.). Crystalline, insol. ordinary solvents. According to Schmidt, picrotoxide obtained by means of AcCl crystallises in needles [225°], sl. sol. cold water and alcohol.

Picrotin $C_{25}H_{30}O_{12}$. [c. 247°]. S. ·16 at 17°; S. (benzene) ·023 at 22° (Schmidt). Constitutes 60 p.c. of crude picrotoxin (B. a. K.). Crystallises with 2½ aq, 3½ aq, and 4½ aq. It is very bitter, but not poisonous. Reduces hot Fehling's solution and ammoniacal $AgNO_3$. H_2SO_4 forms a yellow solution. BzCl forms a benzoyl derivative [245°] (S.).

Anamirtin $C_{19}H_{24}O_{10}$. Constitutes 2 p.c. of crude picrotoxin (Barth a. Kretschy, *M.* 1, 131). Short needles (from water), v. sl. sol. benzene. Neither bitter nor poisonous. Turns brown at 260° and black at 280° without melting.

Cocculin $C_{19}H_{26}O_{10}$. Occurs in small quantity in Cocculus Indicus (Löwenhardt, *A.* 222, 353). Slender needles, sl. sol. hot water, nearly insol. alcohol and ether. Does not give Langley's reaction. Is perhaps identical with anamirtin.

PICRYL. The radicle tri-nitro-phenyl.

PICRYL CHLORIDE *v.* Chloro-tri-nitro-benzene.

PIGMENTS, ANIMAL.

Bile pigments. Bile contains bilirubin, bilifuscin, biliprasin, and probably also biliverdin, which is a product of oxidation of bilirubin. Nitric acid changes the colour of the bile pigments through green, blue, and red to yellow (Gmelin). These colours may be observed by adding nitric acid to a dilute solution of the bile pigments in aqueous alkali, or by gently pouring H_2SO_4 into a solution of the pigments mixed with $NaNO_3$ (Fleischl, *Fr.* 15, 502). The changes in the absorption spectra produced by nitric acid have been studied by Jaffé (*Z.* [2] 5, 666). An alcoholic solution of bromine also produces a play of colours with bile pigments (Capranica, *G.* 11, 430). The absorption spectra of the bile pigments have been studied by Heynsius a. Campbell (*Pf.* 4, 497) and McMunn (*Pr.* 35, 388). Bilirubin, hæmoglobin, and chlorophyll all absorb the violet end of the spectrum, giving an abrupt edge: biliverdin transmits more green; biliprasin, bilifuscin, and bilihumin absorb up to between D and E. The colouring matters of bile are probably got by reduction of hæmatine,

itself formed by the action of bile acids on hæmoglobin (McMunn, *Pr.* 31, 206). According to Latschenberger (*M.* 9, 52), hæmoglobin yields simultaneously melanin and bile pigments. All the colouring matters of bile, including hæmatine, urobilin (in bile), and bilirubin, are oxidised to choletelin, which body apparently passes into blood serum, and is then excreted by the kidneys. The absorption bands of bile are due to choletelin and urobilin.

Bilirubin $C_{32}H_{36}N_4O_6$ (Städeler, *A.* 132, 323; Maly, *A.* 181, 106), or $C_{16}H_{18}N_2O_3$ by Raoult's method (Nencki a. Rotschy, *M.* 10, 568). S. (chloroform) ·17 (Thudichum, *Z.* [2] 4, 554). Ox gall stones are often largely composed of the lime compound of bilirubin (Maly, *A.* 175, 76).

Preparation.—Brown human gall stones are powdered and extracted with ether; the residue is boiled with water, and treated with dilute HCl. The mass is washed, dried, and extracted with chloroform; the chloroform is distilled off, and the residue treated with absolute alcohol. It is then treated with ether and alcohol repeatedly, again dissolved in chloroform, and precipitated by absolute alcohol (Burdon-Sanderson).

Properties.—Orange powder, insol. water, nearly insol. ether, v. sl. sol. alcohol, sol. benzene and chloroform. The colour of the skin in jaundice is probably due to bilirubin. Bilirubin dissolves in alkalis, forming an orange solution, which gradually absorbs oxygen from the air, and then gives a green pp. of biliverdin on adding an acid. An alkaline solution of bilirubin mixed with an equal bulk of alcohol gives, on adding HNO_3 containing nitrous acid, a green colour changing through blue to red. Sodium-amalgam forms hydrobilirubin. Bromine-vapour yields various brominated products (Thudichum, *C. J.* 28, 389; 30, 27). Br in chloroform gives $C_{32}H_{33}Br_3N_4O_6$, a dark bluish-green powder, forming a dark-blue solution in alcohol or ether (Maly, *A.* 181, 106). Chlorine passed into a solution of bilirubin in $CHCl_3$ forms several chlorinated bodies (Thudichum). A solution of *p*-diazobenzene sulphonic acid added to a solution of bilirubin in chloroform mixed with alcohol gives a red colour changing to blue on adding conc. HClAq, and turned red again on adding an alkali (difference from other bile-pigments) (Ehrlich, *Fr.* 23, 275).—$CaC_{32}H_{34}N_4O_6$. Occurs in gall stones. Obtained also by ppg. an ammoniacal solution by $CaCl_2$, as brown flakes drying to a lustrous dark-green mass, which yields a dark-blue powder.

Hydrobilirubin $C_{32}H_{40}N_4O_7$. Obtained by reducing bilirubin in alkaline solution with sodium-amalgam (Maly, *A.* 163, 77). According to McMunn it is not, as had been stated, identical with the urobilin which is found in normal urine, in the urine of febrile patients (Jaffé, *Virchow's Archiv*, 47; Disqué, *H.* 2, 271), and in excrement (Vaulair a. Masius, *Centralbl. f. d. Med. Wissensch.* 1871, No. 24). A similar substance is formed by reducing hæmoglobin, hæmatine, or hæmatoporphyrin in alcoholic solution with tin and HCl (Hoppe-Seyler, *B.* 7, 1065; Le Nobel, *C. C.* 1887, 538; McMunn, *Proc. Physiol. Soc.* 1888, 1), and by the action of H_2SO_4 on a solution of albumen in HOAc (Michailoff, *J. R.* 16, 269). Reddish-brown powder with green lustre, sl. sol. water, v. sol. alcohol, m. sol. ether. Its alkaline solutions are brown, its solution in chloroform is yellowish-red. The alcoholic solution shows an absorption-band near F. Does not give Gmelin's reaction with HNO_3. May be reduced by sodium-amalgam or by tin and HCl to a colourless product, which in acid solutions is reoxidised by air to hydrobilirubin.

Choletelin $C_{16}H_{18}N_2O_6$. Occurs in normal urine, and is obtained by passing nitrous vapours into a solution of bilirubin in alcohol (Heynsius a. Campbell; McMunn, *J. Th.* 1881, 213). Brown amorphous powder, sol. alkalis and alkaline carbonates, alcohol, ether, and chloroform. Ammoniacal $AgNO_3$ ppts. reddish-brown $C_{16}H_{16}Ag_2N_2O_6$. Does not give Gmelin's reaction. Its absorption spectrum contains a broad band from *b* to F.

Biliverdin $C_{32}H_{36}N_4O_8$. Formed by oxidation of a solution of bilirubin by air or by PbO_2. Dark-green powder, insol. water and chloroform, sl. sol. ether, v. sol. alcohol, CS_2, and benzene. Its solutions are green. Its alcoholic solution gives dark-green pps. with baryta-water, ammoniacal $CaCl_2$, and $AgNO_3$. Ag_2O added to its alcoholic solution ppts. bilipurpin, sol. NH_3Aq and reppd. by HCl as a purple powder. Prolonged treatment with Ag_2O converts bilipurpin into yellow biliflavin. HNO_3 added to an alcoholic solution of biliverdin gives a bluish-violet, red, and, finally, yellow colour (Thudichum).

Bilifuscin $C_{16}H_{20}N_2O_4$. Prepared by washing gall stones with ether, hot water, and chloroform, adding dilute HClAq, and extracting with hot chloroform. The extract is evaporated and the bilifuscin dissolved in alcohol, which leaves bilirubin undissolved (Brücke, *J. pr.* 77, 72; Städeler, *A.* 132, 325). Almost black mass, which yields a dark-brown powder. Forms a brown solution in alcohol and alkalis, nearly insol. water, ether, and chloroform. Gives Gmelin's colour-reaction. Ppd. by ammoniacal $CaCl_2$. Simony (*Sitz. W.* [3] 73, 181) obtained from the bile of a corpse a bilifuscin which did not give Gmelin's reaction, and which formed an olive-brown solution in alcohol, HOAc, and alkalis.

Biliprasin $C_{16}H_{22}N_2O_6$. Extracted by alcohol from the residue of gall stones from which bilirubin and bilifuscin have been removed by chloroform (Städeler). Nearly black mass, yielding a greenish-black powder, insol. water, ether, and chloroform, v. e. sol. alcohol, forming a green solution which, unlike one of biliverdin, is turned brown by ammonia. Gives Gmelin's reaction.

Bilihumin. Left after extracting biliprasin with alcohol (S.). Black powder, m. sol. warm NaOHAq. Exhibits Gmelin's reaction.

Bilicyanin. A product of partial oxidation of bilirubin and other bile pigments (Maly, *Sitz. W.* [2] 59, 597). Prepared by adding an alcoholic solution of Br to a solution of bilirubin in chloroform. Occurs in gall stones. Its alcoholic solution is blue, but turned dingy green by alkalis, the blue colour being restored by acids. Bile also contains a blue substance strongly resembling indigo, forming a yellowish solution in alkalis (Ritter, *Bl.* [2] 13, 212; Andouard, *Bl.* [2] 31, 139).

Urinary Pigments. Urine usually contains urobilin (*v. supra*). After urine, containing urobilin, has been mixed with its own bulk of

HClAq and heated to boiling, and then allowed to cool, the urobilin may be extracted by ether and recognised by its absorption band (Grimbert, *J. Ph.* [5] 18, 481). According to McMunn (*Proc. Physiol. Soc.* 1888, 5), there are two kinds of urobilin, one in normal urine and the other in pathological urine, and neither is identical with hydrobilirubin. Normal urobilin is identical with a pigment got from acid hæmatin by successive treatment with H_2O_2 and sodium-amalgam. By the action of oxidising agents indigo-blue and indirubin can be obtained from urine (*v.* Indigo). Pigments can also be obtained by boiling urine with HClAq.

Uromelanin. Prepared by evaporating urine to one-sixth of its bulk at 60°, adding 10 p.c. HCl, and, after two days, removing uric acid by filtration. The filtrate is then boiled for 18 hours, and the ppd. pigment washed with water, alcohol, and ether, dissolved in NaOKAq, and reppd. by H_2SO_4 (Udranski, *H.* 11, 537; 12, 33; *cf.* Plosz, *H.* 8, 89). Brownish-black plates, insol. cold water, ether, and chloroform, sl. sol. alcohol and HClAq, v. sol. isoamyl alcohol and alkalis. Not decomposed at 115°. Potash-fusion yields NH_3, formic, acetic, butyric, and protocatechuic acids and pyrocatechin. Urine contains ·03 p.c. of this substance, which appears to be a humous body formed by decomposition of the reducing substance of normal urine.

Urofuscohæmatin $C_{31}H_{51}N_4O_{13}$ (?) and **ururubrohæmatin** $C_{31}H_{18}N_4FeO_{18}$ (?) were obtained by Baumstark (*B.* 7, 1170) from the urine of a patient suffering from Lepra. Urofuscohæmatin is a black pitchy substance, insol. water, alcohol, ether, chloroform, acids, and NaClAq, sol. alkalis, alkaline carbonates, and alkaline phosphates, forming brown solutions. Ururubrohæmatin is a light blue-black mass, which differs from urofuscohæmatin in not being ppd. when HCl is added to its solution in NaOHAq.

Black pigment in *Melanuria*, *v.* vol. iii. p. 199.

Uroroseïn. An unstable substance which can sometimes be extracted from acidified pathological urine by isoamyl alcohol, to which it imparts a rose colour. The solution shows an absorption band in the green (Nencki a. Sieber, *J. pr.* [2] 26, 333). A similar substance (urorubin) was extracted by ether from urine that had been boiled 15 minutes with 7 p.c. HCl, exposed to air (Plosz, *H.* 8, 85). It was left on evaporation as a dark cherry-red mass. Apparently the same pigment, or rather its leuco- compound, occurs in urine of dogs after administration of skatole (Mester, *H.* 12, 130). The pigment itself is then got by adding HCl to an alcoholic, ethereal, or aqueous extract of the evaporated urine.

OTHER PIGMENTS.

Blood pigments *v.* Hæmoglobin.

Muscle pigments *v.* Muscle.

Eye pigment *v.* Melanin. A purple pigment occurs in the retina of animals. It is insol. ordinary solvents, but dissolves in bile, and in an aqueous solution of the bile acids. It loses its colour in daylight, but recovers it in the dark (Boll, *J. Th.* 1877, 313; Kühne, *J. Th.* 1877, 313; 1878, 279; Ayres, *J. Th.* 1879, 259).

Yellow pigment of animals *v.* Luteïn.

Tetronerythrin. A red pigment extracted by chloroform from the red spot in the eye of the blackcock and red grouse (Wurm, *J.* 1872, 842; 1875, 885; Merejkowski, *J. Th.* 1881, 371). H_2SO_4 gives a blue colour changing to black.

Pyocyanin. Occurs in blue pus (Fordos, *J.* 1860, 596; Lücke, *J.* 1863, 658; Gessard, *J. Th.* 1882, 55). It is formed, together with other pigments, by *Bacillus pyocyanicus* in peptonised gelatin (Babès, *C. R. Soc. Biol.* [9] 1, 438). Blue trimetric prisms or needles (from $CHCl_3$) which become green on keeping, v. sol. chloroform, alcohol, and water. Turned red by acids, but becomes blue again on adding alkalis. It shows two absorption bands, one being in the ultra-violet.

Pigments of Purpura lapillus. The pigments are furnished by a yellowish-white fascia which extends along the rectum (Letellier, *C. R.* 109, 82). This contains two green substances, apple-green monoclinic crystals turned dark blue by light, and dull-green trimetric crystals turned violet or crimson by light. The green substances are sol. ether and chloroform, but become insoluble on exposure to light. The change to purple (punicin) is accompanied by absorption of oxygen (Schunck, *B.* 12, 1359).

Pigments of sea-anemones. *Actinia mesembryanthemum* contains a pigment allied to hæmo-chromogen and hæmato-porphyrin, and to hæmatine. It also contains biliverdin. *Actinia cereus*, *Bunodes ballii*, and *Sagartia bellis* contain a green pigment resembling chloro-fucin, but not identical with any animal or plant chlorophyll (McMunn, *Pr.* 38, 85).

PIGMENTS, VEGETABLE, *v.* Chlorophyll, Alkanet, Beth-a-barra colour, Bixin, Brazileïn, Chica, Coleïn, Curcumin, Dragon's blood, Hæmatoxylin, Lithospermum erythrorhizon, Litmus, Luteic acid, Palmellin, and Santalin.

Anthocyanin. The blue pigment of flowers is sol. water and alcohol, insol. ether. It is free from N, and is turned red by acids and green by alkalis (Fremy a. Cloez, *J. Ph.* [3] 25, 249; Filhol, *C. R.* 39, 194; 50, 345, 1132; Schönn, *Fr.* 9, 328).

Anthoxanthin. Yellow flowers contain anthoxanthin, which is insol. water, and **anthoxantheïn**, which is sol. water. Both are sol. alcohol and ether. The petals of *Rosa gallica* contain a pigment sol. alcohol, insol. ether, which forms amorphous $Pb_2C_{21}H_{30}O_{30}$ (?) (H. Senier, *Ph.* [3] 7, 650). The colouring matter of the berries of *Phytolacca decandra* has been examined by Hilger and Bischoff, *L. V.* 23, 456; *B. C.* 1879, 875).

PILIGANINE. A very poisonous alkaloid occurring in piligan, a Brazilian lycopod (Adrian, *C. R.* 102, 1322). Soft mass, with alkaline reaction, fuming with HCl. Sol. water, alcohol, and chloroform, sl. sol. ether. Emeto-cathartic in action. Its hydrochloride forms minute deliquescent crystals.

PILOCARPENE $C_{10}H_{16}$. (178°). $S.G.^{15}$ ·852. V.D. 4·0. $[\alpha]_D = 1{\cdot}21$. Obtained by steam distillation from jaborandi leaves (Hardy, *Bl.* [2] 24, 498). Fragrant oil. Dextrorotatory. Yields $C_{10}H_{16}2HCl$ [49·5°].

PILOCARPINE $C_{11}H_{16}N_2O_2$ *i.e.*

$$CH{<}\begin{matrix}N{=}CH\\CH.CH\end{matrix}{>}C.CMe{<}\begin{matrix}CO\\NMe_2\end{matrix}{>}O.$$

[159°] (Blyth). $[\alpha]_D = 101{\cdot}6$ in a 7·24 p.c. solution.

Occurs in the leaves and bark of jaborandi (*Pilocarpus*) (Gerrard, *Ph.* [3] 5, 865, 965; Hardy, *Bl.* [2] 24, 497; Kingzett, *C. J.* 30, 367; Harnack a. Meyer, *A.* 204, 67). Prepared synthetically from α-oxy-α-pyridyl-propionic acid $CH_3.C(OH)(C_5H_4N).CO_2H$ by treatment with phosphorus tribromide and heating the resulting $CH_3.CBr(C_5H_4N)CO_2H$ with NMe_3 at 150°. In this way pilocarpidine $C_{10}H_{14}N_2O_2$ is formed, and this is converted into pilocarpine by heating with MeI and MeOH, and oxidising the product with aqueous $KMnO_4$ (Hardy a. Calmels, *C. R.* 105, 68; *Bl.* [2] 48, 233).

Preparation.—Jaborandi leaves are digested with 1 p.c. HClAq, the extract treated with $Pb(OAc)_2$, filtered, and the filtrate ppd. by phosphomolybdic acid. The pp. is decomposed by baryta-water at 100° (Pöhl, *Bl.* [2] 34, 340).

Properties.—Crystalline; begins to sublime at 153°; at 160°–170° the sublimate consists of yellow drops (Blyth). Dextrorotatory. Pilocarpine may be estimated by means of the aurochloride (Christensen, *Ph.* [3] 12, 400). Poisonous, being diaphoretic. Forms resinous compounds with potash, NaOH, and baryta; these compounds are v. sol. water, v. sl. sol. alcohol, and are decomposed by acids, even by CO_2. They may be considered to be salts of pilocarpic acid $C_{11}H_{18}N_2O_3$.

Reactions.—1. Fuming HNO_3 (300 pts.) converts it into pilocarpidine nitrate (Chastaing, *C. R.* 94, 968).—2. *Boiling with water* for twelve hours splits it up into trimethylamine and oxy-pyridyl-propionic acid (Hardy a. Calmels, *C. R.* 102, 1562).—3. Boiling HClAq forms MeOH and pilocarpidine.—4. $KMnO_4$ forms NMe_3, oxy-pyridyl-malonic acid, and finally pyridine (β)-carboxylic acid.—5. *Bromine* added to a chloroform solution forms $C_{11}H_{15}N_2O_2Br_5$, crystallising in minute prisms, converted by moist Ag_2O into di-bromo-pilocarpine $C_{11}H_{14}Br_2N_2O_2$ (Chastaing, *C. R.* 97, 1435). Chlorine forms $C_{11}H_{13}N_2O_2Cl_5$, which is amorphous, and slowly forms crystalline $C_{11}H_{15}N_2O_2Cl_3$.—6. Yields NMe_3 when distilled with potash (Harnack a. Meyer; *cf.* Chastaing, *C. R.* 94, 223).—7. The barium compound on distillation yields jabonine $C_9H_{14}N_2$, an oil with fœtid odour, yielding the amorphous salts $B'AuCl_3$, $B'HAuCl_4$, B'_2PtCl_4, and $B'_2H_2PtCl_6$.

Salts.—$B'HCl$: needles, v. sol. alcohol.—$B'HNO_3$: trimetric lamellæ.—$B'_2H_2PtCl_6$: golden tablets (from hot water).—$B'PtCl_4$: crystals.—$B'HAuCl_4$: minute needles.—$B'AuCl_3$ [88°]: slender needles.—$B'2AuCl_3$: small needles.—$B'HAu_2Cl_7$: minute needles.—$B'AgNO_3$: minute radiating needles.—$B'2AgNO_3$: needles.—$B'CrN_2H_7(SCN)_4$: red silky needles, sol. alcohol (Christensen, *J. pr.* [2] 45, 368).—$B'_2CuO_2H_2$: green powder, ppd. by adding $CuCl_2$ to a solution of pilocarpine in baryta-water.—$B'AgOH$: curdy pp.—$B'Me_2PtCl_6$: crystals.—$B'EtI$. [c. 30°].—$B'EtBr$. [c. 60°]. Very hygroscopic (Chastaing, *C. R.* 101, 507).

Pilocarpidine $C_{10}H_{14}N_2O_2$ *i.e.* $NMe_2.CMe(C_5H_4N).CO_2H$. Occurs in jaborandi leaves (Harnack, *A.* 238, 230). Formed by the action of HClAq or fuming HNO_3 on pilocarpine, by heating dry pilocarpine for twenty-four hours at 120°, by boiling pilocarpine or its baryta compound with water for forty eight hours, and by heating the baryta compound for thirty minutes at 150°. Prepared synthetically by heating $CH_3.CBr(C_5H_4N).CO_2H$ with trimethylamine at 150° (H. a. C.). Very deliquescent, m. sol. water, v. sol. alcohol. Acts physiologically like pilocarpine, but not so strongly. Its alkaline salts are gummy, sol. water, insol. alcohol, and decomposed by CO_2.—$B'HCl$: radiating needles, v. soluble in water.—$B'HAuCl_4$ aq. Rectangular prisms.—$B'AuCl_3$. [145°]. Yellow plates.—$B'_2H_2PtCl_6$ aq: small red prisms.—$B'MeI$.—$B'MeAuCl_4$ [153°]. Prismatic needles. Changes when fused into MeCl and $B'AuCl_3$.

PIMARIC ACID $C_{20}H_{30}O_2$. [211°]. $[\alpha]_D = 72\cdot5$ in a 3·8 p.c. (saturated) alcoholic solution at 15°. Occurs in galipot, the hardened resin of *Pinus maritima* (Laurent, *A. Ch.* [2] 72, 384; [3] 22, 459; Sievert, *Z. f. d. g. Naturwiss.* 14, 311; Maly, *A.* 129, 94; 132, 253; Strecker a. Duvernoy, *A.* 148, 143; 150, 131; Cailliot, *Bl.* [2] 21, 387; Bruylants, *B.* 11, 447; Haller, *B.* 18, 2165; Vesterberg, *B.* 18, 3331; 19, 2167; 20, 3248).

Preparation.—Finely-divided galipot is stirred with half its weight of dilute (70 p.c.) alcohol, left for some days, and squeezed in a cloth. The press-cake is treated several times in this way, finally with 80 p.c. alcohol. The residue is dissolved in somewhat more than the calculated quantity of hot dilute (3 p.c.) NaOHAq. The mixture of Na salts that separates after some days is recrystallised from water, decomposed by HCl, and the free acids crystallised from alcohol or HOAc. (β)-Pimaric acid remains in the mother-liquor.

Properties.—Rectangular plates, insol. water, v. sl. sol. alcohol, ether, and HOAc, m. sol. hot ligroïn, m. sol. hot NaOHAq, sl. sol. NH_3Aq. On shaking the ethereal solution with a drop of ammonia the NH_4 salt separates in slender needles. Not reduced by sodium-amalgam. May be distilled *in vacuo*. Dextrorotatory. HIAq (S.G. 1·96) forms $C_{20}H_{34}$ (320°–330° uncor.). By distillation of the (crude) Ca salt Bruylants obtained ethylene, propylene, amylene, acetone, methyl ethyl ketone, di-ethyl ketone, toluene, xylene, ethyl-toluene, terebene, and diterebene.

Salts.—All the salts are insol. ether. KA' (dried at 100°). Soapy mass of pliant needles.—NaA' 5aq. Slender needles (from 80 p.c. alcohol), sl. sol. cold water.—CaA'_2 aq: needles.—BaA'_2 9aq: pliant needles.—CuA'_2.—PbA'_2.—AgA': amorphous pp., becoming crystalline.

Ethers.—MeA'. [69°].—EtA. [52°].

Chloride $C_{20}H_{29}OCl$. [66°]. Got by adding PCl_5 to a solution of the acid in CS_2. Small prisms, v. e. sol. ether and CS_2.

(β)-Pimaric acid $C_{20}H_{30}O_2$. [140°–150°]. S. 9·26 in 98 p.c. alcohol at 15°. $[\alpha]_D = -272°$ in a 3·17 p.c. alcoholic solution. Obtained as above (Vesterberg, *B.* 20, 3248). Trimetric prisms; *a*:*b*:*c* = ·810:1:·614, insol. water, v. sol. NH_3Aq. Lævorotatory.—NaA': m. sol. ether.—PbA'_2: needles, insol. alcohol and ether. Haller (*B.* 18, 2165) obtained an inactive pimaric acid [c. 149°], which was perhaps a mixture of the dextro- and lævo- varieties.

PIMELIC ACID $C_7H_{12}O_4$ *i.e.* $CO_2H.CHPr.CH_2.CO_2H$. *Isopropyl-succinic acid.* Mol. w. 160. [114°]. *Electrical conductivity*: Walden, *B.* 24, 2037. Formed by fusing camphoric acid with potash (Hlasiwitz a. Grabowski, *A.* 145, 205; Kachler, *A.* 169, 168). Formed also by heating either of the following isopentane tricarboxylic acids: $(CO_2H)_2CPr.CH_2.CO_2H$ or $CO_2H.CHPr.CH(CO_2H)_2$ (Waltz, *B.* 15, 609; *A.* 214, 60; Hjelt, *B.* 16, 2622; Schleicher, *A.* 267, 123). *Obtained also by the action of KOHAq* on isopropyl-acetyl-succinic ether (Roser, *A.* 220, 276). According to Arppe (*J.* 1864, 377) it is not formed, as stated by Laurent (*A. Ch.* [2] 66, 163), by oxidation of oleïc acid. Nodules (from water) or triclinic crystals; *a*:*b*:*c* = ·497:1: ·599; $\alpha = 81° 50'$; $\beta = 100° 2'$; $\gamma = 85° 6'$ (Wreden, *A.* 163, 323; Von Zepharovitch, *Sitz. W.* [1] 73, 7). V. sol. water, alcohol, and ether. Yields butyric acid when fused with potash.

Salts.—$(NH_4)_2A''$. Hygroscopic leaflets.—Na_2A'' (dried at 130°).—CaA″aq: sandy crystalline powder. S. ·47 at 9°; ·25 at 100° (Bauer a. Schuler, *J.* 1878, 734; *B.* 10, 2031; *M.* 4, 345); ·30 at 13° (Roser).—SrA″: nearly insol. hot water, v. e. sol. cold water.—Ag_2A'': pp.

Ethyl ether Et_2A''. (236°–240°).

Chloride $C_7H_{10}O_2Cl_2$. (210°).

Anhydride $C_7H_{10}O_3$. (245°–250°). Got by distilling the acid. Reconverted into the acid by alkalis.

Imide $C_7H_{11}NO_2$. [60°]. Got by heating the ammonium salt. Tables (from water) or small needles (from alcohol-ligroïn). Insol. ligroïn, v. sol. alcohol and ether.

***n*-Pimelic acid** $CH_2(CH_2.CH_2.CO_2H)_2$. [103°]. (272° at 100 mm.) (Krafft a. Noerdlinger, *B.* 22, 818). S. 4·2 at 20°. H.C.p. 828,900. H.F. 243,100 (Stohmann, *J. pr.* [2] 45, 480).

Formation.—1. By heating suberone with HNO_3 (Dale a. Schorlemmer, *C. J.* 35, 686; *A.* 199, 147).—2. By heating furonic acid with HIAq and P at 200° (Baeyer, *B.* 10, 1358).—3. By heating pentane ω-tetra-carboxylic acid (Perkin, jun., *C. J.* 51, 242; 59, 825; *B.* 18, 3249).—4. By oxidation of myristic acid with HNO_3 (Noerdlinger, *B.* 19, 1898).—5. By reducing $CO(CH_2.CH_2.CH_2H)_2$ (*cf.* FURFURYL-ACRYLIC ACID) (Marckwald, *B.* 21, 1398).

Properties.—Rectangular trimetric plates (from water), v. sol. alcohol, ether, and hot benzene. May be sublimed. NaOEt forms $C_{17}H_{28}Na_2O_8$, a white powder, insol. ether, sol. water. Not converted into anhydride by AcCl or by PCl_5 (Volhard, *A.* 267, 82).

Salts.—BaA″aq.—CaA″. Deposited as granular powder when a cold saturated solution is heated.—Ag_2A'': white pp.

Ethyl ether Et_2A''. S.G. $\frac{4}{4}$ 1·0080; $\frac{15}{15}$ ·9988; $\frac{25}{25}$ ·9920. M.M. 11·424. Oil with penetrating odour (Perkin, *C. J.* 59, 826).

Pimelic acid $C_7H_{12}O_4$. [103° cor.]. Got by heating chelidonic acid with HIAq at 205° (Haitinger a. Lieben, *M.* 5, 358). Monoclinic tables, v. sol. hot benzene. Perhaps identical with *n*-pimelic acid.

(β)-Pimelic acid $C_5H_{10}(CO_2H)_2$. [106°]. Occurs among the products of oxidation of castor oil and earth-nut oil with nitric acid (Gantter a. Hell, *B.* 17, 2212). Large tables (from water). Readily forms supersaturated solutions.—BaA″aq: plates.—PbA″.—CuA″.—Ag_2A'': pp.

Iso-pimelic acid $C_5H_{10}(CO_2H)_2$. [104°]. Formed from amylene bromide by successive treatment with alcoholic KCy and HClAq at 170° (Bauer, *M.* 4, 345; Hell, *B.* 24, 1389). Prisms, v. sol. water and alcohol. Begins to form an anhydride at 135°.—$(NH_4)_2A''$.—BaA″1½aq: sandy powder.—CaA″. S. ·2 at 22°; ·14 at 100°.—SrA″4aq.—NiA″2½aq.—ZnA″.—PbA″. S. ·01 at 100°.—CuA″aq. S. ·04 at 16°; ·07 at 100°. Bluish-green plates.—CdA″2aq: needles. S. ·12 at 15°; ·13 at 100°.—Ag_2A''.

An amorphous pimelic acid was got by Bauer, as well as the preceding acid, from amylene bromide. Its Ca salt was more soluble (S. 4·7).

Pimelic acid $C_7H_{12}O_4$. [87°]. Got by oxidising menthol with $KMnO_4$ in acid solution (Arth, *A. Ch.* [6] 7, 455; *C. R.* 107, 107). Needles, v. sol. water. Can be extracted by ether from its aqueous solution.—Ag_2A''.

Isomerides—*v.* DI-METHYL-GLUTARIC ACID, METHYL-ETHYL-SUCCINIC ACID, TRI-METHYL-SUCCINIC ACID, and PROPYL-SUCCINIC ACID.

PIMENTO. The volatile oil obtained from the pods and seeds of *Myrtus Pimenta* contains eugenol and a terpene (255°) S.G. ^{15} ·98 (Bonastre, *J. Ph.* 11, 187; Oeser, *A.* 131, 277).

PINACOLIC ALCOHOL *v.* *Sec*-HEXYL ALCOHOL.

PINACOLIN *v.* METHYL *tert*-BUTYL KETONE.

Benzpinacolin *v.* vol. i. p. 488.

PINACONE $C_6H_{14}O_2$ *i.e.* $CMe_2(OH).CMe_2(OH)$. *Hexylene glycol.* [38°]. (170° cor.). S.G. $\frac{15}{15}$ ·9672; $\frac{25}{25}$ ·9609. M.M. 7·245 (Perkin, *C. J.* 45, 506). H.C. 897,697 (Louguinine, *A. Ch.* [5] 25, 143). Formed by the action of Na or sodium-amalgam on aqueous acetone (Fittig, *A.* 110, 25; 114, 54; Städeler, *A.* 111, 277; Friedel, *A.* 124, 324; *Bl.* [2] 19, 289; Linnemann, *A. Suppl.* 3, 374). Formed also from $CMe_2Br.CMe_2Br$ by successive treatment with AgOAc and baryta (Pawloff, *A.* 196, 122). Small needles (from CS_2), v. sol. cold alcohol and ether, sl. sol. cold CS_2. Sl. sol. cold water, but v. sol. hot water, separating on cooling as a hydrate $C_6H_{14}O_2 6aq$ [46·5°], crystallising in four-sided tables, decomposed by distillation into water and pinacone.

Reactions.—1. *Chromic acid mixture* reconverts it into acetone.—2. Gaseous HI yields PrI and some hexane (Linnemann, *Sitz. W.* [2] 63, 255). HIAq at 100° forms $C_6H_{11}I$ (Bouchardat, *Z.* 1871, 699).—3. Boiling dilute H_2SO_4 converts it into pinacolin. Heating with HOAc has the same effect.—4. $POCl_3$ forms di-chloro-hexane [160°] (Friedel a. Silva, *B.* 6, 35).—5. Does not form an acetal when heated with aldehyde (Lochert, *A. Ch.* [6] 16, 60).—6. When passed through a red-hot tube it yields acetone and isopropyl alcohol (Thörner a. Zincke, *B.* 13, 645).

PINACONES. Compounds of the form HO.CRR′.CRR′.OH, where R and R′ are alkyls. They are obtained by reduction of ketones. On treatment with dehydrating agents they yield (β)-pinacolins $CRR'_2.CO.R$ or isomeric (α)-pinacolins  $O\langle\begin{array}{l}CRR'\\CRR'\end{array}$ or $\begin{array}{l}CRR'.O.CRR'\\CRR'.O.CRR'\end{array}$. If in these formulæ R = H, the (β)-pinacolin will be an aldehyde; while if at the same time R′ = H, we find that glycol is the simplest pinacone, aldehyde the simplest (β)-pinacolin, and ethylene oxide the simplest (α)-pinacolin (Zincke, *A.* 216, 296). Some (β)-pinacolins are decomposed by heating with soda-lime or alcoholic potash, thus: $PhCX_2.COPh + H_2O = PhCX_2H + HOBz$ (Zincke

a. Thörner, *B.* 11, 65; Zagumenny, *J. R.* 12, 429); but phenyl (α)-naphthyl (β)-pinacolin reacts with alcoholic potash, thus:

$PhC(C_{10}H_7)_2COPh + H_2O = PhC(C_{10}H_7)_2OH + Ph.CO.H$

(Elbs, *J. pr.* [2] 35, 506).

PINE-APPLE OIL. Artificial pine-apple oil may be made by dissolving butyric ether in alcohol (Hofmann, *A.* 81, 87).

PINENE *v.* TERPENES.

PINEY TALLOW. A fat obtained by boiling the fruits of *Valeria indica* (of Malabar). Melts at 30° to 38°. Its fatty acids consist of palmitic acid (75 p.c.) and oleïc acid (25 p.c.) (Dal-Sie, *G.* 8, 107).

PINIPICRIN $C_{22}H_{36}O_{11}$. Occurs in the needles and bark of the Scotch fir (*Pinus sylvestris*) and in the green parts of *Thuja occidentale* (Kawalier, *Sitz. W.* 11, 350; 13, 515). Bright-yellow amorphous powder, beginning to soften at 55°, and quite liquid at 100°. Hygroscopic. Tastes bitter. V. sol. water, sol. alcohol, insol. ether. Boiling dilute H_2SO_4 yields glucose (2 mols.) and ericinol $C_{10}H_{16}O$ (1 mol.), *v.* vol. ii. p. 458.

PINITANNIC ACID $C_{14}H_{16}O_8$? Occurs in the needles of the Scotch fir and in the green parts of the *Arbor vitæ* (*Thuja occidentale*) (Kawalier, *Sitz. W.* 11, 357; 29, 19). Reddish-yellow powder, v. sol. water, alcohol, and ether. $FeCl_3$ colours its aqueous solution brown. Gives yellow pps. with lead acetate and subacetate. Not ppd. by gelatin.

PINITE $C_7H_{14}O_6$. *Methyl ether of dextrorotatory inosite.* [186°]. $[\alpha]_D = 65° 51'$. Supposed to be extracted by water from the hardened sap of *Pinus lambertiana* of California (Berthelot, *A. Ch.* [3] 46, 76; Johnson, *Am. S.* [2] 22, 6; Combes, *C. R.* 110, 46; Maquenne, *A. Ch.* [6] 22, 264). Crystalline crusts, v. e. sol. water, almost insol. alcohol. Tastes sweet. Dextrorotatory. Non-fermentable. Does not reduce Fehling's solution. HIAq splits it up into MeI and dextrorotatory inosite [248°]. Pinite is identical with matezite and sennite.

PINOL $C_{10}H_{16}O$ *i.e.* C_6H_6OMePr. (184°). S.G. $\frac{20}{}$ ·953; $\mu_D = 1{\cdot}469$. Formed, together with pinene nitroso-chloride when oil of turpentine is treated with HOAc, nitrous ether, and HClAq (Wallach, *A.* 253, 251; 259, 322; 268, 222; *B.* 24, 1552). Purified by conversion into the dibromide $C_{10}H_{16}Br_2O$ [94°], which is dissolved in dry benzene and treated with sodium-wire. Liquid, smelling like cineol.

Reactions.—1. Oxidised by $KMnO_4$ to CO_2, oxalic acid, and terebic acid [176°].—2. Br forms $C_{10}H_{16}Br_2O$ and $C_{10}H_{15}Br_3O$ [160°]. — 3. HBr forms an addition product converted by water into the hydrate $C_{10}N_{16}OH_2O$ [131°] which is not attacked by Ac_2O, but is reconverted into pinol by warming with dilute H_2SO_4, and yields terpenylic acid [57°] on oxidation by $KMnO_4$.

Dibromide $C_{10}H_{16}Br_2O$. [94°]. (144° at 11 mm.). Trimetric crystals; $a:b:c = {\cdot}570:1:1{\cdot}555$. Insol. water, volatile with steam. Converted by alcoholic potash into 'pinol glycollic ether' $C_{10}H_{16}(OEt)_2O$ [53°] (c. 115° at 14 mm.). AgOAc forms $C_{10}H_{16}(OAc)_2O$ [98°] (127° at 13 mm.), which on saponification by hot dilute H_2SO_4 yields 'pinol-glycol' $C_{10}H_{16}(OH)_2O$ [125°], crystallising in matted needles, v. e. sol. chloroform. Boiling with water and $Pb(OH)_2$ also converts the dibromide into the glycol. Silver propionate yields $C_{10}H_{16}(O.COEt)_2$ [106°]. Formic acid at 100° reduces the dibromide to cymene.

Nitroso-chloride $C_{10}H_{16}ONOCl$. [103°]. Formed by the action of amyl nitrite and HCl on pinol in HOAc (Wallach, *A.* 253, 261). Converted by alcoholic NH_3 into the nitrolamine $C_{10}H_{16}ONONH_2$ (130° at 14 mm.), a viscid mass which yields a crystalline hydrochloride, B'HCl. Aniline, piperidine, and benzylamine form the three analogous bodies $C_{10}H_{16}O.NO.NHPh$ [175°], $C_{10}H_{16}O.NO.NC_5H_{10}$ [154°], and the compound $C_{10}H_{16}O.NO.NHC_7H_7$ [136°], each of which forms a crystalline hydrochloride. (β)-Naphthylamine forms, in like manner, pinol-nitrol-naphthylamine $C_{10}H_{16}O.NO.NHC_{10}H_7$ [195°].

PINYLAMINE $C_{10}H_{15}NH_2$. (208°). S.G. $\frac{17}{}$ ·943. Formed by reducing with zinc-dust and HOAc nitroso-pinene $C_{10}H_{15}NO$ [132°], which is got from $C_{10}H_{16}NOCl$ and alcoholic NaOH (Wallach a. Lorenz, *A.* 268, 197; *B.* 24, 1550). Oil, turning yellow in air, and giving off NH_3. Absorbs CO_2 from air, forming a solid carbonate Benzoic aldehyde forms $C_{10}H_{15}N{:}CHPh$ [58°] furfuraldehyde gives $C_{10}H_{15}N{:}CH.C_4H_3O$ [81°] whilst salicylic aldehyde forms the compound $C_{10}H_{15}N{:}CH.C_6H_4.OH$ [109°].—B'HCl. [230°]. Needles (from water). Yields cymene on distillation.—$B'_2H_2PtCl_6$. Yellow plates or needles.—$B'HNO_3$. Crystals, sl. sol. cold water.—$B'_2H_2SO_4$.—B'HCyS. [136°]. Prisms (from water).—$B'_2H_2C_2O_4$. [248°]. Scales.

Acetyl derivative $C_{10}H_{15}NHAc$. [109°]

Benzoyl derivative. [125°]. Needles.

PINYL-UREA $NH_2.CO.NHC_{10}H_{15}$. [150°]. Formed from pinylamine hydrochloride and potassium cyanate (Wallach, *A.* 268, 204). Needles, v. sol. alcohol.

PIPECOLINE *v.* METHYL-PYRIDINE HEXAHYDRIDE.

PIPERAZINE *v.* PYRAZINE HEXAHYDRIDE.

PIPERHYDRONIC ACID *v.* *Methylene derivative* of DI-OXY-PHENYL-VALERIC ACID.

PIPERIC ACID $C_{12}H_{10}O_4$ *i.e.*

$CH_2{<}^{O}_{O}{>}C_6H_3.CH{:}CH.CH{:}CH.CO_2H$. Mol. w. 218. [217°]. S. (alcohol) ·37 in the cold; 2 at 78°. Formed, together with piperidine, by boiling piperine with alcoholic potash (Von Babo; Strecker, *A.* 105, 317; 118, 280; G. C. Foster, *C. J.* 15, 17; Fittig a. Mielk, *A.* 152, 25; 172, 134). Yellowish needles (from alcohol). After fusion it melts at 213°. Nearly insol. water, m. sol. hot alcohol and ether.

Reactions.—1. Reduced by sodium-amalgam to two hydropiperic acids, which are the methylene derivatives of di-oxy-phenyl-angelic acids $CH_2O_2{:}C_6H_3.CH_2.CH{:}CH.CH_2.CO_2H$ [78°] and $CH_2O_2{:}C_6H_3.CH_2.CH_2.CH{:}CH.CO_2H$ [131°] (Regel, *B.* 20, 414).—2. Dilute alkaline potassium permanganate at 4° oxidises piperic acid to piperonal $CH_2O_2{:}C_6H_3.CHO$ and racemic acid (Doebner, *B.* 23, 2375).—3. *Potash-fusion* yields protocatechuic, oxalic, and acetic acids.—4. *Bromine* in CC_2 forms a tetrabromide which decomposes at 160°–165°.

Salts.—NH_4A'. Satiny scales.—KA'.—BaA'_2. S. ·02 in the cold.—AgA': powder.

Ethyl ether EtA'. [78°]. Plates.

Reference.—BROMO-PIPERIC ACID.

PIPERIDEÏNE. A name for PYRIDINE TETRAHYDRIDE.

Dipiperideïne $C_{10}H_{18}N_2$ *i.e.*  $\begin{array}{l}CH_2.CH_2.CH.CH.CH_2.CH_2\\ CH_2.NH.CH.CH.NH.CH_2\end{array}$ [61°]. Formed by slowly adding *ν*-chloro-piperidine to a boiling 10 p.c. solution of potash in alcohol (Lellmann a. Schwaderer, *B.* 22, 1000, 1318). Monoclinic crystals, sl. sol. water, v. sol. alcohol and ether. Between 200° and 230° it begins to dissociate into (2 mols. of) pyridine tetrahydride; hence it has no constant boiling-point. Slightly volatile with steam. Ac_2O forms an acetyl derivative (220°). S.G. $\frac{16\cdot5}{4}$ 1·0531. Tin and conc. HClAq reduce it to piperidine. Phenyl thiocarbimide gives $C_{10}H_{17}N_2.CS.NHPh$ [144°]. CS_2 forms $C_{10}H_{18}N_2CS_2$, crystallising in needles, and melting at 150° with evolution of gas.

Salt.—$B''H_2Cl_2$ 2aq. [150°]. Plates, liquefies c. 80° when quickly heated.

Isodipiperideïne $C_{10}H_{18}N_2$. Formed by heating diazobenzene piperidide at 250° (Heusler, *A.* 260, 239). Thickish liquid, miscible with water, but can be extracted therefrom by ether. Reduces Fehling's solution and ammoniacal $AgNO_3$. Its salts are hygroscopic.

PIPERIDIC ACID $C_4H_9NO_2$ [184°], which is got by oxidising piperidine *ν*-carboxylic ether with fuming HNO_3 and heating the product with HClAq at 140°, is *γ*-amido-butyric acid (Schotten, *B.* 16, 643; Gabriel, *B.* 23, 1770).

PIPERIDINE $C_5H_{11}N$ *i.e.*

 $CH_2<\begin{array}{l}CH_2.CH_2\\ CH_2.CH_2\end{array}>NH$. *Pyridine hexahydride.* Mol. w. 85. (106°). S.G. $\frac{15}{15}$ ·8664; $\frac{25}{25}$ ·8591. M.M. 5·810 (Perkin, *C. J.* 55, 700). S.V. 108·76. S.H. ·533 (Colson, *Bl.* [3] 3, 8). H.F.v. 24,090. H.F.p. 26,990 (Thomsen, *Th.* 4, 145). Appears to occur in the husks of pepper (Johnstone, *C. N.* 58, 235; *An.* 14, 41).

Formation.—1. By distilling piperine with potash-lime or soda-lime, or by boiling it with alcoholic potash (Wertheim, *A.* 127, 75; Anderson, *A.* 75, 82; 84, 345; Cahours, *A. Ch.* [3] 38, 76; Von Babo a. Keller, *J. pr.* 72, 53).—2. By reduction of pyridine in alcoholic solution by sodium-amalgam; the yield being 75 p.c. of the theoretical (Ladenburg a. Roth, *A.* 247, 51). 3. By heating pentamethylene-diamine hydrochloride (Ladenburg, *B.* 18, 3100).—4. By heating hygric acid $C_6H_{11}NO_2$ with H_2SO_4 for a few minutes at 300° (Liebermann a. Kühling, *B.* 24, 413).

Properties.—Liquid, with ammoniacal and peppery smell, miscible with water. Alkaline in reaction. Caustic taste. Ppts. salts of zinc and copper, but does not redissolve the ppd. hydrates. Not attacked by fuming HClAq at 300° or by boiling HNO_3 (S.G. 1·5). Piperidine acts as an anæsthetic (*B.* 14, 713). Oxidised by H_2O_2 to glutaric acid and its imide and *δ*-amido-valeric aldehyde (Wolffenstein, *B.* 25, 2777).

Reactions.—1. *Bromine* and water at 200° yield di-bromo-oxy-pyridine and some $CHBr_3$ (Hofmann, *B.* 12, 984). Piperidine hydrochloride, heated with dry Br at 180, yields di-bromo-pyridine (Schotten, *B.* 15, 427). Bromine and NaOHAq give crystalline $C_5H_7Br_2NO$ (Hofmann, *B.* 16, 560). Bromine and lime-water yield bromo-piperidine $C_5H_{10}BrN$ [234°] (Lellmann, *B.* 22, 1327).—2. *Chlorine* acts with explosive violence on dry piperidine. In presence of water or chloroform it yields *ν*-chloro-piperidine, which may also be got by using bleaching-powder. It is an unstable, heavy oil (52° at 25 mm.), with pungent odour, and deposits piperidine hydrochloride when kept for some time (Bally, *B.* 21, 1772).—3. Conc. H_2SO_4 at 300° forms pyridine (Kœnigs, *B.* 12, 2341). Nitrobenzene at 260° also oxidises it to pyridine (L.). 4. *Chloroform*, on boiling for some days, yields $CH(C_5H_{10}N)_3$ aq (98° at 15 mm.) (Busz a. Kekulé, *B.* 20, 3246).—5. CH_3CCl_3 forms, on boiling, ethenyl tripiperidine $CH_3.C(C_5H_{10}N)_3$, a liquid (262°) yielding $B'''H_3Cl_3$ and $B'''_2 3H_2PtCl_6$ (B. a. K.).—6. Boiling *oxalic ether* (1 mol.) yields piperidyl-oxamic ether $C_5H_{10}N.CO.CO_2Et$ (289°) (Wallach, *A.* 214, 278; 237, 247). The corresponding acid [129°] splits up on fusion into CO_2 and the formyl derivative of piperidine. PCl_5 yields CO_2 and $C_5H_{10}N.COCl$ (238°), which acts upon piperidine forming $(C_5H_{10}N)_2CO$ [43°] (298°). NH_3Aq converts the ether into piperidyl-oxamide $C_5H_{10}N.CO.CO.NH_2$ [127°], crystallising in monoclinic prisms, converted by P_2O_5 into $C_5H_{10}N.CO.CN$, a heavy oil (264°). When piperidine (2 mols.) is distilled with oxalic ether (1 mol.) there is formed oxalyl-piperidine $C_5H_{10}N.CO.CO.C_5H_{10}N$ [89°] (above 350°).—7. By heating with *phthalic acid* (2 mols.) as long as phthalic anhydride sublimes there is formed 'piperilene-amine-phthaleïn' $C_{18}H_{24}N_2O_2$ or  $C_6H_4<\begin{array}{l}C(NC_5H_{10})_2\\ CO ——— O\end{array}>$, an oil which yields crystalline $C_{18}H_{24}Br_2N_2O_2$ (Piutti, *G.* 13, 535; *A.* 227, 197).—8. *Phthalic anhydride* unites in the cold with piperidine, forming a mixture of 'piperilene-phthalamic acid' $C_5H_{10}N.CO.C_6H_4.CO_2H$ and its piperidine salt (P.). On shaking with ether and water the acid goes into ethereal solution, and the salt into aqueous solution. Piperilene-phthalamic acid is a heavy oil, v. sol. alcohol. It yields AgA', $C_5H_{11}NHA'$ [c. 150°], and $C_{18}H_{26}Br_4N_2O_3$, crystallising in long needles. 9. *Alloxan* and aqueous sulphurous acid give $(C_4H_2N_2O_4)C_5H_{11}NH_2SO_3$, crystallising in plates (Pellizzari, *A.* 248, 150).—10. On heating with *isatin* and alcohol on the water-bath there is formed the compound $C_8H_5NO(C_5H_{10}N)_2$ or  $C_6H_4<\begin{array}{l}C(NC_5H_{10})_2\\ NH ——— CO\end{array}>$, crystallising in flat colourless prisms, m. sol. hot alcohol, turned red by HCl, and yielding a blue dye (indigo?) when treated with Ac_2O, or when rapidly heated to 125°–160°. Bromo-isatin forms, in like manner, $C_8H_4BrNO(C_5H_{10}N)_2$, crystallising in needles, while di-bromo-isatin reacts with production of $C_6H_2Br_2(NH_2).CO.CO.NC_5H_{10}$ [152°] (Schotten, *B.* 24, 1367, 2605).—11. A solution of *diazobenzene chloride* and sodium acetate forms $Ph.N{:}N.NC_5H_{10}$, which yields phenol and piperidine when treated with dilute H_2SO_4, and phenyl-hydrazine and piperidine when reduced by $SnCl_2$ and HCl (Nölting a. Binder, *B.* 20, 3016). Other diazo- compounds act in like manner. Diazobenzene piperidide is decomposed on heating to 250°, yielding benzene, N, and isopiperideïn (Heusler, *A.* 260, 239).—12. *Potassium cyanate* converts piperidine sulphate into $NH_2.CO.NC_5H_{10}$, crystallising from alcohol in needles (Cahours). *Methyl* and *ethyl cyanates* yield corresponding ureas. *Phenyl cyanate* forms $NHPh.CO.NC_5H_{10}$, crystallising from alcohol in prisms [172°]. $C_7H_7NH.COCl$ gives rise to $C_7H_7NH.CO.NC_5H_{10}$ [102°], crystallising from dilute alcohol in needles (Kühn a. Riesenfeld, *B.* 24, 3818).—13. *Methyl thio-carbimide* forms $NHMe.CS.NC_5H_{10}$ [129°] (Hecht, *B.* 23, 287; 25, 815), while *ethyl-*, *propyl-*, and *phenyl- thiocarbimides* form corresponding thio-ureas [46°], [75°], and [99°] respectively. *Phenyl-*, *o-*, and *p-tolyl-thiocarbimides* form $C_5H_{10}N.CS.NHPh$ [98°] (G.); [104°] (Skinner a. Ruhemann, *C. J.* 53, 558) and $C_5H_{10}N.CS.NHC_7H_7$ [98°] and [132°] respectively. *Potassium sulphocyanide* reacts with piperidine sulphate, forming $C_5H_{10}N.CS.NH_2$ [92°] Gebhardt, *B.* 17, 3039). *Allyl-thiocarbimide* forms oily $C_5H_{10}N.CS.NHC_3H_5$, which is converted by conc. HClAq at 100° into $C_5H_{10}N.C\left\langle\begin{array}{l}S.CHMe\\ N.CH_2\end{array}\right.$, a liquid (277°) yielding $B'C_6H_3N_3O_7$ [112°] and B'MeI [67°] (Avenarius, *B.* 24, 262).—14. *Benzoyl-thiocarbimide* added to a solution of piperidine in dry benzene forms $C_5H_{10}N.CS.NHBz$ [123°], crystallising in needles, sol. alcohol and ether (Dixon, *C. J.* 55, 624). *Benzyl-thiocarbimide* gives $C_5H_{10}N.CS.NHCH_2Ph$ [88°] (Dixon, *C. J.* 59, 568).—15. *Tri-methyl-trithiocyanurate* at 200° forms $C_{11}H_{24}N_3S$ [107°], which gives $B'_2H_2PtCl_6$ (Hofmann, *B.* 18, 2779).—16. *Quinone* forms red needles [178°], which are probably $C_6H_2O_2(NC_5H_{10})_2$ (Lachovitch, *M.* 9, 506).—17. *Benzoic aldehyde* in presence of K_2CO_3 forms $CHPh(NC_5H_{10})_2$ [80°] crystallising from alcohol in flat needles (Ehrenberg, *J. pr.* [2] 36, 130; Lachovitch, *M.* 9, 695).—18. *Tri-oxy-methylene* forms $CH_2(NC_5H_{10})_2$ (230°), which unites with CS_2 giving $C_{11}H_{20}N_2CS_2$ [58°].—19. *Pinene nitroso-chloride* in alcoholic or aqueous solution yields crystalline $C_{10}H_{16}NONC_5H_{10}$ [119°] which forms B'HCl. The corresponding terpine and dipentinene derivatives melt at 154° (Wallach, *A.* 241, 320; 245, 253).—20. *Amylene nitroso-nitrate* in boiling alcoholic solution forms $CMe_2(NC_5H_{10}).CMe{:}NOH$, which crystallises from ether in prisms [96°], and is converted by boiling dilute H_2SO_4 into $CMe_2(NC_5H_{10}).CO.CH_3$, an oil (220°), $\mu_D = 1{\cdot}934$, volatile with steam, yielding a very hygroscopic hydrochloride (Wallach, *A.* 248, 172).—21. *Fluorescein chloride* at 220° forms $C_6H_4{:}C_2O_2\left\langle\begin{array}{l}C_6H_3(NC_5H_{10})\\ C_6H_3(NC_5H_{10})\end{array}\right\rangle O$ which yields $B''H_2PtCl_6$ and $B''H_2Cl_2$ which is purple in dilute solution and yellow in conc. HClAq (Lellmann a. Büttner, *B.* 23, 1387).—22. *Bromo-phenanthrene* at 260° forms crystalline $C_{11}H_9NC_5H_{10}$ [113°] which yields $B'_2H_2PtCl_6$ 6aq (L. a. B.).—23. *Bromo-anthracene* at 260° reacts forming $C_{14}H_9NC_5H_{10}$ crystallising from ether in yellow prisms and giving $B'_2H_2PtCl_6$ 2aq (L. a. B.).—24. *Chloro-acetic acid* forms $C_5H_{10}N.CH_2.CO_2H$, which forms hemihedral prisms (containing aq) and yields CuA'_2 4aq, HA'HCl, $HA'HBiI_4$, $(HA')_4 3HAuCl_4$, and $HA'BaCl_2$ (Kraut, *A.* 157, 66).—25. *a-Chloro-propionic ether* produces $C_5H_{10}N.CHMe.CO_2H$ crystallising from water and alcohol in prisms and yielding $HA'HAuCl_4$ (Brühl, *B.* 9, 34).—26. *Benzene sulphochloride* and NaOHAq form $C_6H_5.SO_2.NC_5H_{10}$ [93°] (Hinsberg, *A.* 265, 182; Schotten a. Schlömann, *B.* 24, 3689). This body is oxidised by $KMnO_4$ to $C_6H_5.SO_2.NH.CH_2.CH_2.CH_2.CH_2.CO_2H$.—27. *Picryl chloride* forms $C_5H_{10}N.C_6H_2(NO_2)_3$ [106°] (S. a. S.).—28. *Glycerin dichlorhydrin* forms liquid $C_{10}H_{22}N_2O$ (280°-290°) which yields $B''H_2PtCl_6$ (Ladenburg, *B.* 14, 1879).—29. CS_2 forms $(C_5H_{11}N)_2CS_2$ or $C_5H_{10}N.CS.SNC_5H_{12}$ crystallising in slender monoclinic needles [174°], converted by an alcoholic solution of iodine to $(C_5H_{10}N.CS)_2S_2$ [130°].—30. *Dicyandiamide* reacts on 'piperyl-biguanide' with formation of $C_7H_{15}N_5$, *i.e.* $C_5H_{10}N.C(NH).NH.C(NH).NH_2$ [163°?] crystallising in silky needles, and yielding the salts $B'H_2Cl_2$ [217°], $B'H_2SO_4$ [173°], $B'_2H_2SO_4$ [219°], $B'H_2PtCl_6$ [252°], $B'H_2AuCl_5$, and the copper compound $Cu(C_7H_{11}N_5)_2H_2SO_4$ crystallising in rose-red needles (Bamberger, *B.* 24, 605, 904). Piperyl-biguanide is converted by $CHCl_3$ and caustic potash into 'piperyl-formoguanamine' $C_5H_{10}N.C\left\langle\begin{array}{l}N.C(NH_2)\\ N{=}CH\end{array}\right\rangle N$ [194·5°] which yields the salts B'HCl [201°], $B'_2H_2SO_4$aq [222°], $B'2C_6H_3N_3O_7$ [188°], $B'_2H_2PtCl_6$ [219°], $B'HAuCl_4$ [90°] and [158°], and B'_2AgNO_3 [229°-238°] (Hjelt, *B.* 25, 529). Piperyl-biguanide sulphate heated with NaOAc at 200° yields piperyl-acetoguanamine $C_5H_{10}N.C\left\langle\begin{array}{l}N.C(NH_2)\\ N{:}CMe\end{array}\right\rangle N$ [179°] (Hjelt, *B.* 25, 533). The acetyl derivative of piperyl-biguanide $C_5H_{10}N.C(NAc).NH.C(NH).NH_2$ [193°] is got by heating the copper salt with HOAc.

Salts.—B'HCl. [237°]. M.M. 10·034 in a 53 p.c. solution (Perkin, *C. J.* 55, 716). Needles, v. sol. water and alcohol.—$B'HAuCl_4$ [206°]. Not decomposed by boiling water (De Coninck, *Bl.* [2] 45, 131).—$B'_2H_2PtCl_6$. [196°] (Ladenburg, *B.* 18, 3100); [200°] (Wallach a. Lehmann, *A.* 237, 241). Red needles. Not decomposed by boiling water (De Coninck, *Bl.* [2] 45, 131). Crystallises also with EtOH in orange needles [191°].—B'_2PtCl_2.—$B'Zn_2OCl_2$: amorphous pp. got by adding piperidine to a solution of $ZnCl_2$ (Lachovitch, *M.* 9, 517).—B'HBr. Plates (Lellmann, *B.* 20, 680).—B'HI. Long needles.—$(B'HI)_3 2BiI_3$. Scarlet plates (from alcohol) (Kraut, *A.* 210, 319).—B'ICl. [143°]. White needles.—B'IClHCl. [90°]. Yellow crystals (from water) (Pictet a. Krafft, *Bl.* [3] 7, 72).—$B'HNO_3$. Small needles.—$B'_2H_2C_2O_4$: needles.—$B'_2H_4FeCy_6$ 3aq. Yellow triclinic crystals.—**Piperate** $B'C_{12}H_{10}O_4$. Silky laminæ [100°] (Babo a. Keller).—$B'_2H_2SO_4$.

Nitrosamine $C_5H_{10}N.NO$. (218°). S.G. $^{16.5}$ 1·066. Formed from piperidine and nitrous acid (Wertheim, *A.* 127, 75; Schotten, *B.* 15, 425; Knorr, *A.* 221, 298). Pale-yellow liquid, sl. sol. water, v. sol. conc. HClAq, but reppd. on dilution. Zinc and HClAq reduce it to piperidine and NH_3. Heated in a current of HCl at 100° it gives piperidine and NOCl. Sodium-amalgam forms $C_5H_{10}N.NH_2$ and piperidine.—$B''H_2Cl_2$: syrupy.—$B''HCl$: crystalline mass.

Hydrazine $C_5H_{10}N.NH_2$. '*Piperyl-hydrazine.*' (146°) at 728 mm. S.G. $\underline{14.6}$ ·928. Got by reducing the nitrosamine with zinc-dust and HOAc (Knorr, *B.* 15, 859; *A.* 221, 299). Liquid, with ammoniacal odour, miscible with water, alcohol, and ether. Volatile with steam. Oxidised by HgO in the cold to the tetrazone $C_{10}H_{20}N_4$ [45°], which yields $B'_2H_2PtCl_6$. Reduces cold ammoniacal $AgNO_3$ and hot Fehling's solution. Nitrous acid converts it into piperidine. CS_2 gives rise to $(C_5H_{10}N.NH)_2CS$ [181°]. The compound

$C_5H_{10}N.NH.CS.NC_5H_{10}$ [86°] may also be obtained. BzCl in ether forms $C_5H_{10}N.NHBz$ [196°]. Benzoic aldehyde forms $C_5H_{10}N.N{:}CHPh$ [63°]. **Salt.**—B'HCl. [162°]. Tables (from alcohol). Reacts with potassium cyanate forming $C_5H_{10}N.NH.CO.NH_2$ [136°] and with potassium sulphocyanide forming $C_5H_{10}N.NH.CS.NH_2$ [167°].—*Methylo-iodide* B'MeI. [215°]. Begins to decompose at 150°.

Formyl derivative $C_5H_{10}N.CHO$. (222°). S.G. $^{23}_{4}$ 1·0193. Formed by the distillation of $C_5H_{10}N.CO.CO_2H$ (*v. Reaction* 6) (Wallach a. Lehmann, *A.* 228, 251; 237, 252). Got also by heating piperidine with formamide (Lachovitch, *M.* 9, 699). Liquid, miscible with water, alcohol, and ether. PCl_5 yields a base $C_{11}H_{20}N_2$.—B'HCl: deliquescent needles. — $B'_4H_2PtCl_6$. [172°]. Plates.—$B'HgCl_2$. [149°]. Needles.

Acetyl derivative $C_5H_{10}NAc$. (227°). S.G. ^{0} 1·011 (Wallach a. Kamensky, *A.* 214, 238; *cf.* Schotten, *B.* 15, 426). Liquid, miscible with water. When heated with BzCl it gives AcCl and benzoyl-piperidine (Pictet, *B.* 23, 3014). On heating with bromine it gives pyridine, bromo-pyridine, and di-bromo-pyridine (Hofmann, *B.* 16, 587). When Cl is passed into cooled acetyl-piperidine and the product is warmed with water, there is formed $C_7H_{11}Cl_2NO_2$ [122°] (Bally, *B.* 21, 1772).

Benzoyl derivative $C_5H_{10}NBz$. [48°]. (above 360°). Formed from piperidine, BzCl, and NaOHAq (Cahours; Schotten, *B.* 17, 2544; 21, 2238). Triclinic prisms (from alcohol). Oxidised by $KMnO_4$ to benzoyl-δ-amido-valeric acid [94°]. Benzoic aldehyde forms the compound $NH{<}\begin{matrix}C(CHPh).CH_2\\C(CHPh).CH_2\end{matrix}{>}CH_2$ [89°], which yields B'HCl [166°] and $B'HNO_3$ [98°], both being crystalline (Rügheimer, *B.* 24, 2186).

Bromo-benzoyl derivative $C_5H_{10}N.CO.C_6H_4Br$. The *o-* compound is an oil, while the *p-* compound crystallises from alcohol in rectangular monoclinic tables [95°] (Schotten, *B.* 21, 2248).

m-Nitro-benzoyl derivative $C_5H_{10}N.CO.C_6H_4NO_2$. [34°]. (184° at 54 mm.). S. (alcohol) 33 in the cold, 50 at 78°. Dark-yellow monoclinic crystals. Crystallises from water with about 5aq, and then melts at 84°. Yields, on reduction, the *m*-amido-benzoyl derivative [125°].

Oxy-benzoyl derivative v. Piperidide of OXY-BENZOIC ACID.

Cuminyl derivative $C_{15}H_{21}NO$. Tables.

Cinnamyl derivative $C_8H_7CO.NC_5H_{10}$. [122°]. Formed from the anhydride and piperidine (Herstein, *B.* 22, 2265). Stellate needles.

Alkyl-piperidines. On heating the alkylo-iodides of pyridine, a pair of alkyl-pyridines is produced, that of lower boiling-point being (α)-alkyl-pyridine, and the other (γ)-alkyl-pyridine. On reduction these give the corresponding alkyl-piperidines. The same isopropyl-pyridines are obtained both from pyridine isopropylo-iodide, and pyridine *n*-propylo-iodide, an intramolecular change taking place in the propyl group in the latter case. Conyrine is (α)-propyl-pyridine, coniine is (α)-propyl-piperidine (Ladenburg, *B.* 18, 1587). By adding potash to piperidine alkylo-iodides, ν-alkyl-piperidines can be obtained.

Methyl-, Ethyl-, Propyl-, Phenyl-, and Tolyl-Piperidines v. METHYL, ETHYL, PROPYL, PHENYL, and TOLYL PYRIDINE HEXAHYDRIDES.

PIPERIDINE ν-CARBOXYLIC ACID

$CH_2{<}\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}{>}N.CO_2H$. *Methyl ether* MeA'. (201°). Formed from piperidine, $ClCO_2Me$, and KOHAq (Schotten, *B.* 15, 425; 16, 647). Heavy oil. Converted by HNO_3, containing urea, into $C_5H_7(NO_2)N.CO_2Me$ [103°], whence Br forms a compound [130°].

Ethyl ether EtA'. *Piperyl-urethane.* (211°). Formed from piperidine and $ClCO_2Et$. Oil. Br in HOAc forms $C_5H_7BrN.CO_2Et$ [140°], while HNO_3 free from NO_2 forms 'nitrodehydro-piperyl urethane' $C_5H_7(NO_2)N.CO_2Et$ [52°], whence Br in HOAc forms $C_8H_{13}BrN_2O_5$ [157°].

Chloride $C_5H_{10}N.COCl$. (238°). Formed from $C_5H_{10}N.CO.CO_2H$ and PCl_5 (*v.* PIPERIDINE, *Reaction* 6). Liquid, slowly decomposed by cold water into piperidine, CO_2, and HCl.

Amide $C_5H_{10}N.CO.NH_2$. [106°]. Got from piperidine sulphate and potassium cyanate. Needles. Yields $B'HNO_3$. [67°] (Franchimont a. Klobbie, *R. T. C.* 8, 302).

Anilide. [172°]. Formed from piperidine and phenyl cyanate, or from the chloride and aniline (Gebhardt, *B.* 17, 3040; Wallach, *A.* 228, 250; 237, 250).

Piperidide $(C_5H_{10}N)_2CO$. [43°].

Isomeride *v. Hexahydride of* PYRIDINE CARBOXYLIC ACID.

DI-PIPERIDYL *v.* DIPYRIDYL *dodecahydride.*

PIPERIDYL-CYANURAMIDE *v. Cyanuramide* in article CYANIC ACIDS.

PIPERIDYL-MELAMINE *v.* CYANIC ACIDS.

PIPERILENE *v.* vol. iii. p. 807.

PIPERINE $C_{17}H_{19}NO_3$ *i.e.* $C_5H_{10}N.CO.CH{:}CH.CH{:}CH.C_6H_3{:}O_2CH_2$. *Piperyl-piperidine.* Mol. w. 285. [128°]. Occurs in black pepper (*Piper nigrum*), long pepper (*P. longum*), and in the black pepper of Western Africa (*Cubeba Clusii*) (Oersted, *S.* 29, 80; Pelletier, *A. Ch.* [2] 16, 344; 51, 199; Merck, *N. J. T.* 20, 1, 34; Wackenroder, *Br. Arch.* 37, 347; Duflos, *S.* 61, 22; Warrentrapp a. Will, *A.* 39, 283; Wertheim, *A.* 70, 58; Gerhardt, *Compt. Chim.* 1849, 375; *A. Ch.* [3] 7, 253; Anderson, *A.* 75, 82; 84, 345; Cahours, *A. Ch.* [3] 38, 76; Stenhouse, *A.* 95, 106; Von Babo a. Keller, *J. pr.* 72, 53; Strecker, *A.* 105, 317).

Formation.—By heating piperidine with the chloride of piperic acid (Rügheimer, *B.* 15, 1390).

Preparation.—Ground pepper (1 pt.) is boiled with slaked lime (2 pts.) and water, the filtrate evaporated to dryness at 100°, and the piperine extracted with ether and recrystallised from alcohol (Cazeneuve a. Caillot, *Bl.* [2] 27, 290).

Properties.—Monoclinic prisms, v. sl. sol. hot water, m. sol. alcohol and ether. Inactive to light. Insol. dilute acids and alkalis. Decomposed by alcoholic potash into piperic acid and piperidine. Conc. H_2SO_4 forms a blood-red solution. HNO_3 gives a greenish-yellow colour changing to red. Phosphomolybdic acid gives a flocculent pp.

Salts.—The hydrochloride is crystalline, but decomposed by water.—$B'_4H_2PtCl_6$: roseate monoclinic crystals. Not decomposed by hot water (De Coninck, *Bl.* [2] 45, 131).—B'_2HHgCl_3:

triclinic crystals.—B'_2HI_3. [145°]. Steel-blue needles (Jörgensen, *J. pr.* [2] 3, 328).

PIPEROKETONIC ACID *v.* Di-oxy-benzyl ethyl ketone carboxylic acid.

PIPERONAL *v.* *Methylene derivative* of Protocatechuic aldehyde.

PIPERONYL-ACRYLIC ACID *v.* *Methylene ether* of Caffeic acid.

PIPERONYL ALCOHOL *v.* *Methylene derivative* of Di-oxy-benzyl alcohol.

PIPERONYLIC ACID *v.* *Methylene derivative* of Protocatechuic acid.

PIPEROPROPIONIC ACID *v.* Di-oxy-phenyl-propionic acid.

PIPER-PROPYL-ALKINE *v.* Oxy-propyl-piperidine.

PIPERYL. This name is given to radicle $CH_2O_2:C_6H_3.CH:CH.CH:CH.CO$. *Piperyl* has also been used to denote C_5H_{10}, the divalent radicle which is united to NH in piperidine; many of the derivatives of this divalent 'piperyl' are described under Piperidine.

PIPERYLENE *v.* Pentinene.

PIPERYLENE TETRABROMIDE *v.* Tetra-bromo-pentane.

PIPITZAHOÏC ACID $C_{15}H_{20}O_3$. *Perezone.* [104°] (A. a. L.); [107°] (Mylius, *B.* 18, 480). May be extracted by alcohol from Pipitzahuac root or *Radix Perezia* (De la Sagra, *C. R.* 42, 873, 1072; Weldt, *A.* 95, 188; Anschütz a. Leather, *C. J.* 49, 715; *B.* 18, 709, 715). Flat golden plates (from alcohol), nearly insol. water, v. sol. alcohol and ether. May be sublimed. Volatile with steam. Aqueous alkalis form a violet solution. Aqueous methylamine forms methyl-amido-pipitzahoïc acid $C_{15}H_{19}(NHMe)O_3$ [114°], crystallising in blue needles, while aniline forms $C_{15}H_{19}(NHPh)O_3$ [139°], *o*-toluidine gives $C_{15}H_{19}(NHC_7H_7)O_3$ [110°], *p*-toluidine yields *p*-tolyl-amido-pipitzahoïc acid [134°]. Bromine forms $C_{15}H_{20}Br_2O_3$ [109°].

S a l t s.—$PbC_{15}H_{18}O_3$.—CuA'_2.—AgA': purple pp.

Ethyl ether EtA'. [141°].

Acetyl derivative $C_{15}H_{19}AcO_3$. [115°]. Trimetric plates; $a:b:c = \cdot629:1:\cdot845$.

Oxim? $C_{15}H_{21}NO_3$. *Amidopipitzahoïc acid.* [154°]. Flat violet-brown needles. Formed from the acid and alcoholic hydroxylamine (Mylius, *B.* 18, 936). The same body is got by boiling phenyl-amido-pipitzahoïc acid (*v. supra*) with NH_3Aq (A. a. L.).

Oxypipitzahoïc acid $C_{15}H_{18}(OH)_2O_2$. [129°] (A. a. L.); [134°] (M.). Formed by warming phenyl-amido-pipitzahoïc acid (*v. supra*) with alcoholic H_2SO_4. Orange plates, nearly insol. water. Its alkaline solutions are violet. Bromine forms an unstable dibromide [140°–146°]. On warming with H_2SO_4 it is converted into perezinone $C_{15}H_{18}O_3$ [144°], which crystallises in yellow needles or prisms, and yields $C_{15}H_{17}NaO_3$, crystallising in easily soluble yellow tables.

PIRYLENE C_5H_6 *i.e.* $CH\Big\langle{CH.CH_2 \atop CH:CH}$. (60°). **Formed by distilling with solid NaOH the methylo-iodide of the base obtained by the action of Ag_2O on the iodide formed from di-methyl-pyridine hexahydride and iodine (Ladenburg, *A.* 247, 60). Oil. Does not ppt. ammoniacal Cu_2Cl_2.**

PISCIDIN $C_{29}H_{24}O_8$. [192°]. The poisonous principle of Jamaica dogwood (*Piscidia Erythrina*), from which it can be extracted by lime-water (Hart, *Am.* 5, 39). Six-sided prisms (from alcohol), insol. water, sl. sol. cold alcohol, sol. benzene, $CHCl_3$, and conc. HClAq. Sedative and narcotic.

PITTAKAL *v.* Eupittonic acid.

PITURINE is Nicotine.

PLASMINE *v.* Proteïds.

PLATINAMMINES *v.* Platinum-ammonium compounds, p. 292.

PLATINATES. PtO_4H_4 acts as an acidic hydroxide towards strong bases, forming compounds of the type $xPtO_2.yMO$. These *platinates* are generally obtained by reacting on $PtCl_4Aq$ with caustic or carbonated alkalis, and sometimes by fusing $PtCl_4$ with bases and then washing with water.

Barium platinates. The compound $2PtO_2.3BaO$ was obtained, in hexagonal crystals, by Rousseau (*C. R.* 109, 144) by heating $PtCl_4$ with BaO for some time, then adding $BaCl_2$ equal to the quantity of BaO used, and heating to c. 1100° (m.p. of Cu) in a Pt dish for some hours, and washing with water. The crystals are insol. acetic acid, but sol. HClAq. The salt decomposes at an orange-red heat, in presence of $BaCl_2$, with separation of Pt. Topsöe (*B.* 3, 462) obtained $PtBaO_3.4H_2O$ by decomposing H_2PtCl_6Aq by excess of BaO_2H_2 in sunlight; to the pp. thus obtained Johannsen (*A.* 155, 204) gave the composition

$$3PtBaO_3.BaCl_2.PtOCl_2.11H_2O.$$

Calcium platinates. According to Herschel (*A.* 3, 317), CaOAq added to $PtCl_4Aq$ in sunlight produces a white pp. of

$$PtCaO_3.CaO.PtOCl_2.7H_2O.$$

Sodium platinates. When a mixture of Na_2CO_3Aq and H_2PtCl_6Aq stands for some days in a warm place, a pp. of $3PtO_2.Na_2O.6H_2O$ separates (Döbereiner a. Weiss, *A.* 14, 21). Rousseau (*C. R.* 109, 144) obtained crystals of Na platinate by heating a mixture of equal weights of NaOH and NaCl with some Pt black, in a Pt crucible, to c. 1100 for two or three hours.

For descriptions of the *bromoplatinates, chloroplatinates, iodoplatinates,* &c., *v.* Platini-bromides, Platini-chlorides, Platini-iodides, &c.

THIOPLATINATES. PtS_2 combines with some more basic sulphides to form salts which may be called *thioplatinates*; some salts are also known containing Pt and Sn combined with alkali metal and S, these may be called *thiostannoplatinates*. The alkali thioplatinates are obtained by fusing together spongy Pt, S, and alkali carbonate, and washing with water, wherein the thioplatinates are insoluble. Other thioplatinates—of Cd, Cu, Fe, Pb, Mn, Hg, Ag, Tl, Sr, and Zn—are obtained by double decomposition from the alkali salts. The thioplatinates belong to the forms $M^I_2Pt_4S_6$ and $M^I_4Pt_3S_6$; the corresponding *thioplatinic acids* $H_2Pt_4S_6$ and $H_4Pt_3S_6$ are obtained by decomposing $K_2Pt_4S_6$ and $Na_4Pt_3S_6$ respectively by dilute HClAq.

Potassium thioplatinate

$K_2Pt_4S_6 = K_2S.3PtS.PtS_2$ (*Potassium platin-thioplatinate*). Blue-grey, metal-like crystals; S.G. 6·44 at 15°. Glows like tinder when heated in air, forming K_2SO_4 and Pt; reduced in H with

evolution of H_2S and formation of Pt. Obtained by fusing an intimate mixture of 1–2 parts Pt black with 12 parts of a mixture of equal parts of S and K_2CO_3 in a porcelain crucible, keeping the molten mass over the blowpipe for a few minutes and extracting with water when cold.

Sodium thioplatinate $Na_4Pt_3S_6 = 2Na_2S.2PtS.PtS_2$ (*Disodium platinthioplatinate*). Copper-red, rhombic needles; decomposed in air. Obtained similarly to the K compound mentioned above.

For details regarding thioplatinates, and also thiostannoplatinates, *v.* Schneider, *P.* 136, 105; 138, 604; 139, 661; 141, 519; 148, 633; 149, 881 (*cf.* E. von Meyer, *J. pr.* [2] 15, 1).

M. M. P. M.

PLATINITES, *derivatives of*; *v.* Platino-bromides, Platino-chlorides, Platino-nitrites, &c.

PLATINI- and PLATINO- COMPOUNDS. Such compounds as *platini-bromides*, called also *bromoplatinates*, and *platino-nitrites* will be described here.

PLATINI- COMPOUNDS. These compounds are derived from platinic compounds, especially from $PtCl_4$, $PtBr_4$, and PtI_4; they generally react as salts of acids containing tetravalent atoms of Pt in their acidic radicles.

Platini-bromhydric acid $H_2PtBr_6.9H_2O$ (*Bromoplatinic acid*). Formed by heating spongy Pt with Br, and HBrAq (b.p. 126°), in a sealed tube, to 180° (Meyer a. Züblin, *B.* 13, 404; Halberstadt, *B.* 17, 2962). Also by dissolving Pt black in HNO_3Aq mixed with HBrAq, heating with repeated additions of HBrAq, evaporating over CaO, and washing the crystals, on an asbestos filter, with CS_2 (H., *l.c.*). Large, clear, carmine-red, monoclinic crystals; v. sol. water, alcohol, ether, acetic acid, and $CHCl_3$. Melts at 100° with partial decomposition (Topsöe, *Ar. Sc.* 35, 58; 45, 223).

Platini-bromides $M^I_2PtBr_6$ (*Bromoplatinates*). Thomsen (*Th.* 3, 430) gives $[Pt,Br^4,2RBrAq] = 57,160$ and $[Pt,O^2,6RBrAq] = 80,360$, where $R = H$, Na, K, Am, $\frac{1}{2}Ca$, $\frac{1}{2}Ba$, $\frac{1}{2}Sr$, $\frac{1}{2}Mg$. These salts are generally formed by evaporating H_2PtBr_6Aq, or a solution of Pt in Br and HBrAq, with metallic bromides. They are red crystalline solids, isomorphous with the corresponding Cl salts. As solutions of these salts give a pp. of Ag_2PtBr_6, and not AgBr, with a limited quantity of cold $AgNO_3Aq$, and on electrolysis of their solutions the Pt goes with the Br to the positive electrode, they are better regarded as ordinary salts than as double salts $2MBr.PtBr_4$.

Ammonium platini-bromide Am_2PtBr_6. Red octahedra; S.G. 4·2; sl. sol. cold water. S. at 20° = ·59 (Halberstadt, *B.* 17, 2962). Formed by evaporating $H_2PtBr_6Aq + NH_4Br$.

Potassium platini-bromide K_2PtBr_6. Red octahedra; S.G. 4·54 (Topsöe, *Ar. Sc.* 35, 58; 45, 228). S. 2·07 at 20°, 10 at 100° (H., *l.c.*). Obtained by ppg. H_2PtBr_6Aq by KBr, or by evaporating H_2PtCl_6Aq with KBr. Thomsen (*Th.* 3, 430) gives
$[Pt,Br^4,2KBr] = 59,260$; $[K^2PtBr^6,Aq] = -12,260$.

Double compounds with K_2PtCl_6 are described by Pitkin (*C. N.* 41, 118).

Sodium platini-bromide $Na_2PtBr_6.6H_2O$. Dark-red, triclinic prisms; S.G. 3·323; very sol. water and alcohol. Obtained by evaporating $PtCl_4Aq$ with HBr till the Cl is turned out, adding NaBrAq, evaporating to dryness, dissolving in a little water, and crystallising (Thomsen, *J. pr.* [2] 15, 294). Thomsen (*Th.* 3, 430) gives $[Pt,Br^4,2NaBr,6H^2O] = 65,330$; $[Na^2PtBr^6,6H^2O] = 18,540$; $[Na^2PtBr^6.6H^2O,Aq] = -8,550$. Platini-bromides of Ba with 10aq, Ca with 12aq, Co with 12aq, Cu with 8aq, Pb, Mg with 12aq, Mn with 12aq, Ni with 6aq, Sr with 10aq, and Zn with 12aq, are described by Topsöe (*Ar. Sc.* 35, 58; 45, 223); von Bonsdorff (*P.* 19, 343) describes a Mn salt with 6aq.

Platini-bromonitrites (*Nitro-bromoplatinates. Platini-nitrobromides*). Salts derived from the platini-bromides by replacing Br by NO_2. By gently heating $K_2Pt(NO_2)_4$ (*v.* Platino-nitrites, p. 284) with Br, *potassium platini-dibromonitrite*, $K_2PtBr_2(NO_2)_4$, is obtained as a yellow powder, sl. sol. cold, more sol. hot, water (Vèzes, *C. R.* 112, 616). When an aqueous solution of this salt is concentrated at a gentle heat, it yields crystals of *potassium platini-tribromonitrite*, $K_2PtBr_3(NO_2)_3$ (V., *C. R.* 115, 44). *Potassium platini-tetrabromonitrite*, $K_2PtBr_4(NO_2)_2$, is obtained by the regulated action of Br on $K_2Pt(NO_2)_4$; it forms red prisms, sol. water with partial decomposition (V., *C. R.* 115, 44).

Platini-chlorhydric acid $H_2PtCl_6.6H_2O$ (*Chloroplatinic acid*). A solution of this compound is the starting-point for the preparation of very many Pt compounds. Formed by dissolving Pt in *aqua regia*, repeatedly evaporating with conc. HClAq till every trace of HNO_3 is expelled, and allowing to crystallise (Weber, *P.* 131, 441; Jörgensen, *J. pr.* [2] 16, 345; Topsöe, *Ar. Sc.* 35, 58). Red-brown, very deliquescent crystals; S.G. 2·431. Easily sol. alcohol, forming $H_2PtCl_4(OEt)_2$ (Schützenberger, *A. Ch.* [4] 21, 362). Heated to 230°, gives $PtCl_2$ (*v.* Platinum dichloride, *Preparation*, p. 289). Heated in Cl to above 350° gives $PtCl_4$ (*v.* Platinum tetrachloride, *Formation*, p. 289). By adding much H_2SO_4 to $H_2PtCl_6.6H_2O$ in a little water, Pigeon (*C. R.* 112, 1218) obtained the hydrate with $4H_2O$; and by heating *in vacuo* at 100°, over fused KOH, he obtained $HPtCl_5.2H_2O$. Thomsen (*Th.* 3, 430) gives $[2HClAq,Pt,Cl^4] = 84,620$; $[6HClAq,Pt,O^2] = 64,060$. Pigeon (*C. R.* 110, 77) gives $[H^2PtCl^6.6H^2O,Aq] = 4,340$. H_2PtCl_6Aq reacts as a dibasic acid; the *platini-chlorides* are numerous and important; the Am and K salts are only sl. sol. water and insol. alcohol, and are much used as forms for estimating K and ammonia. Very many organic bases replace H and form salts analogous with the metallic platini-chlorides.

Platini-chlorides $M^I_2PtCl_6$ (*Chloroplatinates*). Thomsen (*Th.* 3, 430) gives $[Pt,Cl^4,2RClAq] = 84,620$; and $[Pt,O^2,6RClAq] = 64,060$; where $R = H$, Am, K, Na, $\frac{1}{2}Ba$, $\frac{1}{2}Ca$, $\frac{1}{2}Sr$, $\frac{1}{2}Mg$. Pigeon (*C. R.* 110, 77) gives $[PtCl^4,2HClAq] = 24,800$. These salts are generally obtained by evaporating H_2PtCl_6Aq with metallic chlorides. Most of them are yellow-red, crystalline solids; usually e. sol. water and alcohol. They are better regarded as ordinary salts than as double chlorides (*cf.* Platini-bromides, *supra*). The platini-chlorides were investigated by von Bonsdorff (*P.* 17, 250); later by Cleve (*Bl.* [2] 21, 118, 197, 247, 345); also by Topsöe (*Ar. Sc.* 35, 58); and by Nilson (*B.* 9, 1056, 1142). Crystallographically considered, these salts fall into four groups:—(1) M_2PtCl_6, where M = Am, Cs, K, Rb, Tl (and Pt may be replaced by Pd, Ir, or Sn); regular, isomorphous with Am_2(or K_2)$PtBr_6$, Am_2(or K_2)PtI_6, fluosilicates, fluostannates, and fluozirconates of similar composition. (2) $MPtCl_6.6aq$, where M = Cd, Co, Cu, Fe, Mg, Mn, Ni, Zn (and Pt may be replaced by Pd or Sn); hexagonal. (3) $MPtCl_6.12aq$, where M = Mg or Mn; hexagonal; isomorphous with corresponding platini-bromides. (4) $M(PtCl_6)_2.24aq$, where M = Ce_2 or La_2; hexagonal.

AMMONIUM PLATINI-CHLORIDE Am_2PtCl_6 (*Ammonium chloroplatinate. Platinsalammoniac*). Ppd. on adding NH_4Cl to H_2PtCl_6Aq, $PtCl_4Aq$, or a solution of Pt in conc. HClAq with a little HNO_3. Yellow, regular, octahedral crystals. S.G. 3·065 (Topsöe, *l.c.*). S. ·665 at 20°, 1·25 at 100° (Michaelis, *G.-O.* 1, 1187). Scarcely sol. alcohol or ether. Decomposed at red heat, leaving Pt black. For reactions with NH_3 *v.* PLATINUM-AMMONIUM COMPOUNDS, p. 292.

POTASSIUM PLATINI-CHLORIDE K_2PtCl_6 (*Potassium chloroplatinate*). Ppd. by adding KCl, or other K salt, to conc. H_2PtCl_6Aq, or to a solution containing Pt which has been evaporated with excess of HClAq. Reddish-yellow regular octahedra. S.G. 3·586 (Bödeker). S. ·74 at 0°, 1·12 at 20°, 2·17 at 50°, 3·79 at 80°, 5·13 at 100° (Michaelis, *l.c.*). Almost insol. alcohol, or alcohol and ether. Slightly sol. dilute acids; sol. KOHAq. Reduced to Pt and KCl by heating to redness; more quickly by heating with reducing agents such as oxalic acid or sulphurous acid, or by heating in a stream of hydrogen. Vèzes (*C. R.* 110, 757) describes a *nitroso- derivative*, $K_2Pt(NO)Cl_5$. Pigeon (*C. R.* 110, 77; 112, 791) gives $[Pt,Cl^4,2KClAq] = 83,330$; $[PtCl^4,2KClAq] = 25,330$; $[PtCl^4,2KCl] = 29,700$. Thomsen (*Th.* 3, 430) gives $[Pt,Cl^4,2KCl] = 89,500$.

Potassium platini-bromochloride $K_2PtBr_2Cl_4$; by ppg. H_2PtCl_6Aq by KBr (Pitkin, *C. N.* 41, 118).

The following platini-chlorides have also been isolated: $AlCl_3.PtCl_4.15aq$ (Welkow, *B.* 7, 804; Salm-Horstmar, *P.* 99, 638); Ba, with 4aq (Topsöe; Bornsdorff, Precht, *Fr.* 1879. 509); Be, with 8aq (Welkow, *B.* 6, 1288; Thomsen, *B.* 3, 827); Cd, with 6aq (Topsöe); Cs (Crookes, *C. N.* 9, 37; Bunsen, *P.* 119, 371); Ca, with 9aq (Topsöe; Precht); Ce, various salts (Cleve, Marignac, Holzmann, *J. pr.* 84, 80); $CrCl_3.PtCl_4.10aq$ (Nilson, *B.* 9, 1056, 1142); Co, with 6aq (Topsöe); Cu, with 6aq (T.); Di, various salts (Frerichs a. Smith, *A.* 191, 331); $2InCl_3.5PtCl_4.36aq$ (Crookes, *J.* 1864. 256); Fe, various salts (T.; Bonsdorff; Nilson); La, various salts (Cleve, Marignac, Jolin, *B.* 11, 910); Pb, with 3 or 4aq (Birnbaum, *J.* 1867. 319; Topsöe); Li, with 6aq (Scheibler, *J. pr.* 67, 485; Jörgensen a. Topsöe, *Gm.-K.* 3, 1174); Mg, with 6aq (T.); Mn, with 6aq (T.); Ni, with 6aq (T.); Rb (Crookes; Bunsen); Ag (Birnbaum); Na, with 6aq (Marignac, Topsöe, Precht; for thermal data *v.* Thomsen, and Pigeon, *l.c.*); Sr, with 8aq (Bonsdorff); Tl (Crookes); Th, with 12aq (Cleve); Sn, with 12aq (Nilson). Compounds of $PtCl_4$ with chlorides of Er (Nilson), Hg (Birnbaum), VO (Brauner, *M.* 3, 89), and ZrO (Nilson) probably exist. No compounds are formed with $PtCl_4$ and chloride of Sb, As, or Bi.

Platini-chloronitrites (*Platini-nitrochlorides. Nitrochloroplatinates*). Salts derived from the platini-chlorides by replacing Cl by NO_2. A few of these salts are described by Vèzes (*C. R.* 115, 44); the principal are *dichloronitrite* $K_2PtCl_2(NO_2)_4$, *trichloronitrite* $K_2PtCl_3(NO_2)_3$, and *pentachloronitrite* $K_2PtCl_5(NO_2).H_2O$ (*v.* also Blomstrand, *J. pr.* [2] 3, 214).

Platini-iodhydric acid $H_2PtI_6.9H_2O$ (*Iodoplatinic acid*). Brown deliquescent crystals; probably monoclinic; by dissolving PtI_4 in HIAq, and evaporating. Easily decomposed, even in solution, rapidly at 100°, with separation of PtI_4 (Topsöe, *Ar. Sc.* 38, 297; Clementi, *J.* 1855. 420; Lassaigne, *A. Ch.* [2] 51, 113).

Platini-iodides $M^I_2PtI_6$ (*Iodoplatinates*). Reddish-brown, metal-like salts; generally formed by evaporating H_2PtCl_6Aq with excess of metallic iodides, or by adding iodides to PtI_4Aq. The following have been described (*v.* Topsöe, Clementi, Lassaigne, *l.c.*): Am; Ca, with 12aq; Co; Fe; Mg, with 9aq; Mn; Ni, with 6aq; K; Na, with 6aq; Zn, with 9aq.

Platini-iodonitrites (*Platini-nitro-iodides. Nitro-iodoplatinates*). $M^I_2PtI_{6-x}(NO_2)_x$. A few of these salts are described by Vèzes (*C. R.* 113, 696). A *nitroso-platini-iodide*, $K_2Pt(NO)I_5$, is also described.

Platini-molybdates. By boiling $Pt(OH_4)$ with an acidified solution of Na molybdate, Gibbs (*Am. S.* [3] 14, 61) obtained a complex compound which may provisionally be classed as a platini-molybdate, $4Na_2O.10MoO_3.PtO_2.29H_2O$.

Platini-nitrobromides; *v.* PLATINI-BROMONITRITES, p. 282.

Platini-nitrochlorides; *v.* PLATINI-CHLORONITRITES, *supra*.

Platini-nitro-iodides; *v.* PLATINI-IODONITRITES, *supra*.

Platini-tungstates. Complex compounds of PtO_2, WO_3, and strong bases (*v.* Gibbs, *Am. S.* [3] 14, 61; Rosenheim, *B.* 24, 2397).

PLATINO- COMPOUNDS. These compounds are derived from platinous compounds, especially from $PtCl_2$, $PtBr_2$, and PtI_2; they generally react as salts of acids of the form H_2PtX_4, where X is a monovalent negative radicle, generally Cl, Br, or I.

Platino-bromhydric acid H_2PtBr_4 (*Bromoplatinous acid*). This compound is probably contained in a solution of $PtBr_2$ in HBrAq.

Platino-bromides $M^I_2PtBr_4$ (*Bromoplatinites*). Only one of these salts, K_2PtBr_4, has been isolated. *Potassium platino-bromide* is obtained by adding a very little water to a mixture of the corresponding Cl salt and NaBr, in the ratio $K_2PtCl_4 : 4NaBr$, boiling, sucking up the clear liquid from ppd. NaCl, and allowing to cool, when the salt crystallises in dark-brown octahedra, or brown-red needles, which are very sol. water (Thomsen, *J. pr.* [2] 15, 294). Thomsen (*Th.* 3, 430) gives $[2KBr,Pt,Br^2] = 82,310$.

Platino-bromonitrites *v.* PLATINO-NITRITES, p. 284.

Platino-chlorhydric acid H_2PtCl_4 (*Chloroplatinous acid*). This acid has not been isolated; but it almost certainly exists in a solution of

$PtCl_2$ in HClAq, in the liquid obtained by decomposing $BaPtCl_4$ by the equivalent quantity of H_2SO_4Aq (Nilson, *J. pr.* [2] 15, 260), and in the solution formed when conc. H_2PtCl_6Aq is added to hot conc.K_2PtCl_4Aq (Thomsen, *J. pr.* [2] 15, 294). When these liquids are evaporated *in vacuo*, a residue is obtained agreeing in composition with the formula $HPtCl_3.2H_2O$ ($= HCl.PtCl_2.2H_2O = H_2PtCl_3(OH).H_2O$) ; at 100° this loses H_2O and HCl and leaves $PtCl_2$ (Nilson, *l.c.*).

Platino-chlorides $M^I{}_2PtCl_4$ (*Chloroplatinites*). These salts are obtained by evaporating metallic chlorides with $PtCl_2Aq$, or in many cases by reducing platini-chlorides. Most of the platino-chlorides are very soluble in water, and crystallise only from very conc. solutions, generally forming dark-red crystals. Many of them are described by Nilson (*J. pr.* [2] 15, 260). Thomsen (*Th.* 3, 430) gives $[Pt,Cl^2,2MClAq] = 41,830$; and $[Pt,O,4MClAq] = 31,550$; where $M^I =$ H, K, Na, Am, $\frac{1}{2}$Ba, $\frac{1}{2}$Ca, $\frac{1}{2}$Sr, or $\frac{1}{2}$Mg.

AMMONIUM PLATINO-CHLORIDE Am_2PtCl_4 (*Ammonium chloroplatinite*). Obtained, in four-sided prisms, by adding AmCl to $PtCl_2$ in HClAq, and evaporating; also by reducing hot Am_2PtCl_6Aq by SO_2, or hot H_2PtCl_6Aq by SO_2 and then adding AmCl (Peyrone, *A.* 55, 205; Thomsen, *B.* 2, 668; Grimm, *A.* 99, 95). $[Pt,Cl^2,2AmCl] = 43,550$ (*Th.* 3, 430).

POTASSIUM PLATINO-CHLORIDE K_2PtCl_4 (*Potassium chloroplatinite*). Large, ruby-red, four-sided prisms; S.G. 3·2909 at 21°; easily sol. water, insol. alcohol (Nilson). An aqueous solution is not ppd. by soda or potash when cold; on boiling, all the Pt is thrown down as $Pt(OH)_2$ (Thomsen, *J. pr.* [2] 15, 295). $[Pt,Cl^2,2KCl] = 45,170$ (*Th.* 3, 430). Obtained by adding KCl to $PtCl_2$ in HClAq, and evaporating (Magnus, *P.* 14, 241); also by reducing K_2PtCl_6Aq by H_2S (Böttger, *J. pr.* 91, 251), or better by Cu_2Cl_2 (Thomsen, *J. pr.* [2] 15, 294). K_2PtCl_6 is made into a paste with water, warmed, and moist Cu_2Cl_2 is added, little by little, until a small excess is present; the liquid, which is nearly black, is filtered, the red crystals which separate on cooling are washed with alcohol and re-crystallised.

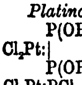
The following platino-chlorides have been isolated and described: Ba, with 3aq; Be, with 5aq; Ca, with 8aq; Cs (Böttger, *J. pr.* 91, 251); Co, with 6aq; Cu, with 6aq (Thomsen, *l.c.*; Millon a. Commaille, *C. R.* 57, 822); Fe^{ous}, with 6aq; Pb; Li, with 6aq; Mg, with 6aq; Mn, with 6aq; Ni, with 6aq; Rb; Ag; Na, with 4aq; Sr, with 6aq; Tl; Zn, with 6aq (Hünefeld, *S.* 60, 197). Compounds of $PtCl_2$ with the chlorides of the following metals are also described by Nilson (*l.c.*); Al, Ce, Cr, Di, Er, La, Th, and Y.

Platino-chloronitrites; *v.* PLATINO-NITRITES, *infra.*

Platino-chlorophosphates (*Phospho-platino-chlorides*). Several salts, and a few acids, containing Pt, Cl, and P have been isolated by Schützenberger (*Bl.* [2] 17, 482; 18, 101, 148). The classification of these compounds is very incomplete. The following scheme is accepted as provisional (*cf.* Seubert, *Ladenburg's Handwörterbuch der Chemie*, 9, 314):

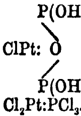
Platino-chlorophosphoric acid $Cl_2Pt:P(OH)_3$; by dissolving $Cl_2Pt.PCl_3$ in water and crystallising; $(Cl_2Pt:PO_3)_2Pb_3.8aq$, and various esters, isolated.

Platino-chlorodiphosphoric acid



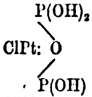
$Cl_2Pt:\begin{matrix}P(OH)_2\\|\\P(OH)_2\end{matrix}$; by the action of moist air on $Cl_2Pt:PCl_3.PCl_3$; ethyl ester also isolated.

Platino-chloropyrophosphoric acid



; by warming a solution of $Cl_2Pt:PCl_3.PCl_3$.

Platino-chloro-anhydropyrophosphoric acid



; by heating the foregoing acid to 150°.

Ethyl diplatino-chloro-phosphate $\begin{matrix}Cl_2Pt\\Cl_2Pt\end{matrix}\!>\!P(OEt)_3$; by dissolving $\begin{matrix}Cl_2Pt\\Cl_2Pt\end{matrix}\!>\!PCl_3$ in alcohol; corresponding acid not isolated (Cochin, *C. R.* 86, 1402).

Platino-cyanides and derivatives; *v.* vol. ii. p. 344.

Platino-iodhydric acid H_2PtI_4 (*Iodoplatinous acid*). This acid probably exists in a solution of PtI_2 in HIAq.

Platino-iodonitrites; *v.* PLATINO-NITRITES.

Platino-nitrites, *and derivatives.* Platinous nitrite $[Pt(NO_2)_2]$ has not been isolated; but several compounds are known in which the group $Pt(NO_2)_2$ forms part of the acidic radicle. These platino-nitrites belong to the form $M_2Pt(NO_2)_4$; they are not to be regarded as double salts, but as derivatives of the acid $H_2Pt(NO_2)_4$; the ordinary reagents for Pt do not show the presence of this metal in solutions of these salts, nor do these solutions give the reactions of nitrites; their solutions doubtless contain the ions M and $Pt(NO_2)_4$. Most of the platino-nitrites are obtained from the potassium salt $K_2Pt(NO_2)_4$, which is formed by the reaction of equivalent weights of K_2PtCl_4 and KNO_2.

PLATINO-NITROUS ACID $H_2Pt(NO_2)_4$ has not been obtained pure, but it doubtless exists in the solution obtained by decomposing $BaPt(NO_2)_4$ by H_2SO_4Aq; on evaporation, this solution gives red crystals (Lang, *J. pr.* 83, 415), but the process causes partial decomposition to *triplatino-octonitrous acid* $H_4Pt_3O(NO_2)_8.2H_2O$ (Nilson, *B.* 10, 934).

POTASSIUM PLATINO-NITRITE $K_2Pt(NO_2)_4$ (*Potassium nitroplatinite*). Small, lustrous, colourless, monoclinic prisms; by mixing solutions of equivalent weights of K_2PtCl_4 and KNO_2, and evaporating (Topsöe, *J.* 1879. 307). S. 3·8 at 15°; more sol. hot water. Combines with Br and Cl to form *potassium platini-dibromo-[dichloro-] nitrites*, $K_2PtBr_2[Cl_2](NO_2)_4$. Most of the other platino-nitrites are obtained from this salt, by adding $AgNO_3Aq$, separating $Ag_2Pt(NO_2)_4$, and decomposing this by metallic chlorides; or making $BaPt(NO_2)_4$, by the action of $BaCl_2Aq$ on the silver salt, and decomposing this by sulphates (Nilson, *B.* 9, 1722; 10, 930; 11, 879; *v.* also Blomstrand, *J. pr.* [2] 3, 186).

The other platino-nitrites which have been

isolated are: Al, Am, Cd, Ce, Cr, Co, Di, Sr, Fe, La, Pb, Li, Mg, Mn, Hg, Ni, Ag, Na, Tl, Y, and Zn.

PLATINO-BROMONITRITES $M^I_2Pt(NO_2)_{4-x}Br_x$. A few of these salts have been obtained by Vèzes (*C. R.* 113, 696; 115, 44). *Potassium platino-bromonitrite* $K_2PtBr(NO_2)_3$ and *dibromo-nitrite* $K_2PtBr_2(NO_2)_2$ are described.

PLATINO-CHLORONITRITES $M^I_2Pt(NO_2)_{4-x}Cl_x$. Vèzes (*l.c.*) has described the *potassium monochloro-salt* $K_2PtCl(NO_2)_3$, and the *dichloro-salt* $K_2PtCl_2(NO_2)_2$.

PLATINO-IODO-NITRITES $M_2Pt(NO_2)_{4-x}I_x$ (Nilson, *B.* 10, 930; 11, 879; Groth, *Z. K.* 4, 469; Vèzes, *C. R.* 115, 44). *Potassium platino-di-iodo-nitrite* $K_2PtI_2(NO_2)_2.2H_2O$ is obtained, in small, black crystals, by the action of an alcoholic solution of I on $K_2Pt(NO_2)_4$. The other salts isolated are those of Al, Am, Ba, Be, Cd, Cs, Ca, Ce, Co, Cu, Di, Fe, La, Pb, Li, Mg, Mn, Ni, Rb, Ag, Na, Sr, Tl, Y, and Zn.

Platino-nitrobromides; *v.* PLATINO-BROMONITRITES, *supra.*

Platino-nitrochlorides; *v.* PLATINO-CHLORONITRITES, *supra.*

Platino-nitro-iodides; *v.* PLATINO-IODONITRITES, *supra.*

Platino-oxalic acid and **platino-oxalates** $H_2Pt(C_2O_4)_2$ and $M^I_2Pt(C_2O_4)_2$ (Söderbaum, *Bl.* [2] 45, 188). The *sodium salt* $Na_2Pt(C_2O_4)_2.4H_2O$ is obtained, in copper-coloured crystals, by heating $Na_2O.3PtO_2.6H_2O$, with 1½ parts crystallised oxalic acid, cooling the blue-coloured liquid, treating the brown needles which separate with hot water, and crystallising; sometimes the salt separates with $5H_2O$ as golden-coloured crystals. The other salts are obtained by double decomposition from the Na salt; they seem to exist in two forms corresponding with the two sodium salts. *Platino-oxalic acid* $H_2Pt(C_2O_4)_2.2H_2O$ is obtained as red, lustrous, metal-like crystals by decomposing the silver salt with the equivalent weight of HClAq, filtering, and concentrating the blue solution *in vacuo.* Salts of the following metals are described by Söderbaum (*l.c.*): Am, Ba, Ca, Mg, Mn, Ni, K, Ag, Na, Sr, and Zn.

Platino-phosphochlorides *v.* PLATINO-CHLOROPHOSPHATES, p. 284.

Platino-seleno-stannates. Schneider (*J. pr.* [2] 44, 507) has described two salts, $K_2Pt_3SnSe_6$ and $Na_2Pt_3SnSe_6$, which may be called platino-seleno-stannates. They are formed by heating together Pt black, $SnSe_2$, K_2CO_3 or Na_2CO_3, and Se.

Platino-stannates. This name may be given to some compounds derived from the acids $H_4Pt_2Sn_2O_8$ and $H_2Pt_2Sn_2O_4$, described by Schneider (*P.* 136, 105) and Schützenberger (*C. R.* 98, 985); *cf.* also Lévy a. Bourgeois (*C. R.* 94, 1365).

Platino-sulphocyanhydric acid, and salts *v.* vol. ii. p. 357.

Platino-sulphonates, ***and derivatives*** (Liebig, *A.* 23, 23; Litton a. Schnedermann, *A.* 42, 316; Birnbaum, *A.* 139, 164; 152, 137; 159, 116; Döbereiner, *J. pr.* 15, 315; Lang, *J. pr.* 83, 415). (*Platino-sulphites. Sulpho-platinites.*) When K_2PtCl_4 is heated with $KHSO_3Aq$, or SO_2 is passed into K_2SO_3Aq holding $Pt(OH)_4$ in suspension, the liquid is neutralised by K_2CO_3 and evaporated, yellow, microscopic crystals are obtained of $K_2Pt(KSO_3)_4.2H_2O$. From this *potassium platino-sulphonate* other similar salts are obtained. These salts are better regarded as derived from *platino-sulphonic acid* $H_2Pt(HSO_3)_4$ than as double compounds of $PtSO_3$ and $K_2SO_3[K_2Pt(KSO_3)_4 = PtSO_3.3K_2SO_3]$; they are analogous to the platino-chlorides M_2PtCl_4 and the platino-nitrites $M_2Pt(NO_2)_4$. The *ammonium*, *sodium*, and *silver* salts have been isolated. *Sodium-platino-oxy-sulphonic acid* $Na_2Pt(HSO_3)_2O$ and *ammonium-platino-oxy-sulphonic acid* $Am_2Pt(HSO_3)_2O$ have also been isolated.

PLATINO-CHLOROSULPHONATES (*Platino-chlorosulphites. Sulpho-chloroplatinites*). $M^I_2Pt.Cl_3.M^ISO_3$. The *potassium salt* $K_2Pt.Cl_3.KSO_3$ is obtained by warming K_2PtCl_4 with SO_2Aq, evaporating, and adding KCl. *Ammonium platino-chlorosulphonic acid* $Am_2Pt.Cl_3.HSO_3$ crystallises from a solution of Am_2PtCl_6, or Am_2PtCl_4, in warm conc. SO_2Aq; the *potassium* and *sodium salts* of this acid are known. A complex acid, $AmH.Pt.Cl.SO_3.HSO_3$, and the salts $AmK.Pt.Cl.SO_3.KSO_3$ and $Am_2.Pt.Cl.SO_3.SO_3Am$ have been isolated.

Platino-thiosulphates. A few salts have been obtained which may be regarded as compounds of hypothetical platinous thiosulphate and sodium thiosulphate $PtS_2O_3.xNa_2S_2O_3.yH_2O$, where x is 3, 4, 6, and 7. They may also be looked on as derivatives of the hypothetical acid $H_2Pt(S_2O_3H)_x$, where H is replaced by Na (Schottländer, *A.* 140, 200; Jochum, *C. C.* 1885. 642).
M. M. P. M.

PLATINUM. Pt. At. w. 194·3. Mol. w. unknown. Melts at c. 1775° (Violle, *C. R.* 89, 702); older determinations generally gave m.p. c. 2000° (for references *v.* Carnelley's *Melting and Boiling Point Tables*, p. 10), although Becquerel (*C. R.* 57, 855) gave 1460°–1480°. S.G. 21·48 to 21·5 at 17·6°, after melting in H (Deville a. Debray, *C. R.* 81, 839; for other values *v.* Clarke's *Specific Gravity Tables*, 2nd edit. p. 15). S.H. ·03243 (Regnault); ·0314 (Dulong a. Petit); ·0317 + ·000012t at t° (Violle, *P. M.* [5] 4, 318). C.E. (linear at 40°) ·00000899 (Fizeau, *C. R.* 68, 1125, for Pt that had been melted); from 0° to 100°, ·00000881 (Calvert a. Johnson, *B. A.* 1858. for hammered Pt). T.C. (Ag = 1000) 379 (C. a. J., *l.c.*); c. 84 (Wiedemann a. Franz, *J.* 1855. 91). Heat of fusion c. 5276 (for 194 g.) (Violle, *l.c.*). E.C. (Ag = 100) 8·042 at 12°–13° (Becquerel, *A. Ch.* [3] 17, 242); 10·53 at 20·7° (Matthiessen, *P.* 103, 428). For electrical resistance of Pt wire *v.* Arndtsen (*P.* 104, 1). Crystallises in the regular system (*v. infra, Properties*). For chief lines in emission-spectrum *v. B. A.* 1884. 436.

Occurrence.—Alloyed with Ir, Pd, Rh, Au, Cu, and Fe in the sands of many rivers, often associated with titaniferous iron and chrome-iron, and in the older rocks in different parts of the world. The quantity of Pt in 'platinum ores,' varies from c. 50 to c. 90 p.c. A Canadian Ni ore was found by Clarke a. Catlett to contain from ·008 to ·02 p.c. Pt (*Am. S.* 37, 372). In 1741 Watson received some particles of a metal-like substance from the gold-bearing sand of the river Pinto in New Granada; the shining silvery particles were called in the district where they occurred *platina del Pinto* (*platina* = diminutive of Spanish *plata* = silver). Watson extracted a new metal from the substance sent him, and called it platinum (*T.* 1750. 585). For a short account of the history of the Pt metals, *v.* Noble metals, iv. 628.

Formation.—1. By decomposition of $PtCl_4$ or $(NH_4)_2PtCl_6$ by heat.—2. By heating an alloy of Pt and Pb in a current of air, whereby the Pb is oxidised and the Pt remains.—3. By reducing many Pt salts by Zn, Fe, NaOHAq and $FeSO_4$Aq, Na_2CO_3Aq and sugar, alcohol added to an alkaline solution, &c.

Preparation.—1. The Pt ore is obtained as a fine powder by fusing with 2 or 3 times its weight of Zn, powdering the brittle alloy so formed, and removing the Zn by dilute H_2SO_4Aq (Descotils, *G. A.* 27, 231; Hess, *J. pr.* 40, 498). The residue is heated to redness, then warmed with HClAq (to remove portions of the baser metals), and then treated with cold *aqua regia* which dissolves Au. The residue is heated, in retorts, with *aqua regia*; the solution contains most of the Pt, along with Rh, Pd, and a little Ir; in the residue are found osm-iridium (*v.* vol. iii. p. 47), Ru, and a little Pt. The acid is distilled off, carrying with it most of the Os as OsO_4; the concentrated solution is neutralised by Na_2CO_3, and the Pd is ppd. as $PdCy_2$ by $HgCy_2$; NH_4Cl is added to the filtrate, and $(NH_4)_2PtCl_6$ is thus ppd. mixed with some $(NH_4)_2IrCl_6$. The Ir salt may be removed by digesting with slightly warm KCNAq until the undissolved portion is light yellow; the salt $IrCl_3.3NH_4Cl$ is thus formed and dissolved, while $(NH_4)_2PtCl_6$ remains (Wöhler a. Mucklé, *A.* 104, 368). Or the NH_4.Pt and NH_4.Ir chlorides may be dissolved in hot water, and the Ir salt reduced to $IrCl_3.3NH_4Cl$, which dissolves, by SO_2 (*cf.* Iridium, vol. iii. p. 46). The residual ammonium platinichloride is then heated until all NH_3 and Cl are volatilised.—2. Finely-divided Pt ore is dissolved in *aqua regia* diluted with 2 pts. water, under increased pressure (which aids the solution); the solution is evaporated, and the residue is heated to 125°, whereby the chlorides of Pd and Ir are reduced to the lower chlorides; treatment with HClAq dissolves $PtCl_4$, which is ppd. as $(NH_4)_2PtCl_6$ by addition of NH_4Cl (Heræus, *v.* Hofmann's *Chem. Industrie auf der Wiener Weltausstellung*, 2, 999; *v.* also Dullo, *J. pr.* 78, 869).—3. Commercial Pt is melted with 6 times its weight of Pb, the granulated alloy is treated with dilute HNO_3Aq (1:8 by volume), which dissolves most of the Pb, Cu, Pd, and Rh; the black residue is dissolved in diluted *aqua regia*—Ir remains undissolved—the solution is evaporated with H_2SO_4Aq, whereby Pb is removed as $PbSO_4$, the filtrate and washings are mixed with excess of NH_4Cl and some NaCl, heated to 80°, and allowed to stand for some days; the pp. is washed repeatedly with saturated NH_4ClAq, and then with very dilute HClAq; it is then dried, heated to dull redness in a Pt vessel with $KHSO_4$ and a little NH_4HSO_4, and washed with boiling water—Rh goes into solution as Rh-K disulphate, and finely-divided Pt remains (Matthey, *Pr.* 28, 463). For other methods *v.* Deville a. Debray, *A. Ch.* [3] 56, 385; 61, 5.—4. Pure Pt is obtained by evaporating a solution of the ore in *aqua regia* with HClAq till HNO_3 is nearly removed, adding NaOHAq till strongly alkaline, boiling for a long time (the alkalinity gradually disappears, owing to formation of NaClOAq), adding alcohol, and then making the turbid liquid acid by HClAq, filtering from olive-green $IrCl_3$, and ppg. by conc. NH_4ClAq (W. von Schneider, *A. Suppl.* 5, 261). The Pt obtained by strongly heating the ppd. $(NH_4)_2PtCl_6$ should be dissolved in diluted *aqua regia*, and re-ppd. by addition of NH_4Cl; on heating this pp. pure Pt remains (Seubert, *A.* 207, 8). For another method of obtaining pure Pt, *v.* Mylius a. Förster, *B.* 25, 665.

The finely-divided Pt obtained by the above methods may be fused into a lump by the use of the O-H flame. The metal is placed in a cavity made in a block of lime (made by strongly heating marble), which is covered by another block, through the top of which a hole is pierced to admit the flame (*v.* Deville a. Debray, *A. Ch.* [3] 56, 385; *cf.* Platinum in Dictionary of Applied Chemistry).

Platinum black, which is extremely finely-divided Pt, is obtained by reducing solutions of some Pt salts by certain organic reducing compounds, or by Zn or Mg, &c. $PtCl_4$Aq may be reduced by Mg (Böttger, *J. pr.* [2] 2, 137), zinc-dust or Fe in powder (Brunner, *A.* 109, 253), $FeSO_4$Aq and NaOHAq (Hempel, *A.* 107, 97), sugar and Na_2CO_3Aq, or by alcohol. Pt black is also formed by fusing Pt with twice its weight of Zn, powdering the alloy, dissolving out Zn by H_2SO_4Aq, and washing with very dilute HNO_3Aq (Döbereiner, *A.* 17, 67). Loew (*B.* 23, 289) recommends to dissolve 50 g. $PtCl_4$ in 50-60 c.c. water, to add c. 70 c.c. formic aldehyde solution of 40 to 45 p.c., to cool, and then to add gradually 50 g. NaOH in 50 c.c. water, to set aside for 12 hours, and then to filter and wash until the washings pass through black, when the washing should be stopped for some hours, and continued when the washings again pass through colourless (O is absorbed and temperature rises); the residue is washed until quite free from NaCl, and dried over H_2SO_4. Liebig (*P.* 17, 101) dissolved $PtCl_2$ in warm conc. KOHAq, added alcohol to the hot liquid till CO_2 came off freely, decanted, washed the ppd. Pt, successively, with alcohol, HClAq, KOHAq, and finally, several times, with boiling water.

Crystals of platinum are obtained by heating Pt to redness, in a glass or porcelain tube, in a stream of dry Cl, for twenty-four hours (Hodgkinson a. Lowndes, *C. N.* 58, 158, 223; Seelheim, *B.* 12, 2066; Joly, *N.* 43, 541; *cf.* Troost a. Hautefeuille, *C. R.* 84, 94). Joly (*N.* 43, 541) obtained cubical crystals of Pt, about ·1 mm. in length, by sprinkling some finely-powdered topaz on a ribbon of Pt, and heating to bright redness by an electric current for c. two hours. Moissan (*C. R.* 109, 807) obtained crystalline Pt by heating dry PtF_4, in a Pt tube, to bright redness. Pt that has been melted shows a crystalline structure when touched with *aqua regia* (*cf.* Koettig, *J. pr.* 71, 190; Noguès, *C. R.* 47, 832; Kalischer, *B.* 15, 706; Mallet, *Am. S.* [2] 20, 340; Phipson, *C. N.* 5, 144).

Treatment of platinum residues.—Pt residues accumulated in the laboratory generally contain Pt as $(NH_4)_2PtCl_6$; the liquid portion usually contains alcohol. The solid part is warmed, in a water-bath, with K_2CO_3Aq, KOHAq, or NaOHAq, and the alcoholic liquid is added little by little, or HCO_2Na is added (Duvillier, *C. R.* 84, 444), till the salt is reduced to Pt. The black residue is washed, dried, boiled with HClAq, and again washed and dried (Knösel, *B.* 6, 1159).

Properties.—Compact platinum is a white metal with a greyish tinge; it is easily polished, thereby acquiring a very high lustre. Much softer than Ag, rather softer than Cu; thin plates or wire can be cut easily with scissors. Without taste or smell. Very malleable and ductile; a wire 2 mm. diameter breaks with a weight of 124 kilos; tenacity is, therefore, c. same as Fe. Pure Pt can be drawn into very thin wire; by fusing into Ag wire, drawing out, and dissolving away the Ag, a wire of Pt ·0009 mm. diameter is said to have been obtained (Gaiffe, *C. R.* 1877. 625). Most easily fused of Pt metals except Pd; very thin wire melts in the outer blow-pipe flame; larger masses require the O-H flame. Becomes soft and workable much below its m.p. Melts in an ordinary fire, owing to combination with C or Si (Heraeus, *D. P. J.* 167, 132; Deville, *A. Ch.* [3] 46, 182; Boussingault, *C. R.* 82, 591; Schützenberger a. Colson, *C. R.* 94, 1710). Crystallises in the regular system, chiefly in octahedral and dodecahedral forms (*v.* Seelheim, *B.* 12, 2066). Said to volatilise to some considerable extent when kept molten (Deville a. Debray, *C. R.* 44, 1101). By heating in certain gases, especially in Cl, volatile compounds are formed and again decomposed. Molten Pt absorbs O, and 'spits' when cooled rapidly.

Pt occludes H. According to Graham (*P. M.* [4] 36, 63), Pt foil absorbs five to six times its own volume of H at a dull-red heat; Berthelot (*C. R.* 94, 1383) says that Pt absorbs from 80 to 120 times its volume of H, probably with formation of definite compounds. Berliner (*W.* 35, 791; *cf.* Neumann, *M.* 13, 40) found that ordinary Pt foil absorbed 127 volumes of H; foil that had been quite freed from gases and cleaned absorbed 200 vols. of H and 80 vols. of O or CO. The whole of the occluded gas is removed, with difficulty, by strongly heating *in vacuo*; under ordinary conditions about 80 vols. of H are retained. O is also occluded by Pt foil, and the condensed O brings about oxidations, *e.g.* electrolytic gas (H_2+O) explodes when exposed to Pt foil at c. 180° (Berliner, *l.c.*). Pt is pervious to H at a bright-red heat; Graham (*P. M.* [4] 32, 401, 503) found that 489·2 c.c. H passed, per minute, through Pt foil 1·1 mm. thick and having a surface of 1 square metre. Gases other than H scarcely diffused through at all.

Pt is not acted on by pure HClAq, HNO_3Aq, or H_2SO_4Aq, nor is it attacked by O; various mixtures of acids dissolve it. Pt is acted on by Cl and by substances which evolve Cl; also, at high temperatures, by molten alkalis, nitrates, KCN, a mixture of alkali carbonates with S, by P and Si, and by most of the metals.

Platinum black is a porous, heavy, very finely-divided black powder, which becomes metal-like, grey, and lustrous when rubbed; S.G. 15·8 to 17·6. Pt black absorbs large quantities of certain gases, especially O; according to Döbereiner (*A.* 17, 67), from 173 to 253 vols. O are occluded by 1 vol. Pt black. The O condensed in Pt black is able to bring about many processes of rapid oxidation: H, CO, C_2H_4, C_2H_6O gas, Et_2O vapour, &c., are rapidly oxidised, generally with ignition (*v.* von Mulder, *R. T. C.* 2, 44; Schönbein, *J. pr.* 98, 76; *P.* 105, 258; von Mulder a. van der Meulen, *R. T. C.* 1, 167); alcohol is oxidised to acetic acid, formic and oxalic acids to CO_2 and H_2O, As_2O_3 to As_2O_5 (von Mulder, *R. T. C.* 2, 44). Pt black charged with H acts as a reducer; water is formed when the hydrogenised Pt black is brought into O (Wilm, *B.* 14, 878; Berthelot, *C. R.* 94, 1377); aqueous solutions of $KClO_3$, KNO_3, K_4FeCy_6, also $C_6H_5NO_2$, &c., are reduced (Gladstone a. Tribe, *C. N.* 37, 245); ozone is reduced to O (von M. a. van der M., *l.c.*). One cause of these actions is probably the heat produced during the condensation of the gases in the porous Pt (*cf.* Berthelot, *A. Ch.* [5] 30, 519); it is not probable that an oxide of Pt is formed and then reduced (*v.* V. Meyer, *J. pr.* [2] 14, 124; *cf.* Tommasi, *B.* 11, 811).

The at. w. of Pt has been determined (1) by strongly heating $PtCl_2$ (Berzelius, *P.* 8, 179 [1813]); (2) by determining Pt in K_2PtCl_6, and by finding the ratio of Pt:KCl in the same salt (B., *P.* 13, 469 [1826]; Andrews, *Chem. Gazette*, 1852. 379); (3) by analyses of K_2PtCl_6 and $(NH_4)_2PtCl_6$ (Seubert, *A.* 207, 29 [1800]; Halberstadt, *B.* 17, 2962 [1884]; *cf.* Dittmar a. McArthur, *E. Tr.* 33, 561 [1888], and criticism thereon by Seubert, *B.* 21, 2179); (4) by determining S.H. of solid Pt (Violle, *P. M.* [5] 4, 318). As no V.D. of a Pt compound has yet been determined, the at. w. cannot be found by the direct application of the law of Avogadro. The older determinations gave 196 to 197; Seubert proved that the true value is c. 194·5, which is between the values for Ir (192·5) and Au (196·8). No compound of Pt has been gasified from which the valency of the atom of Pt in gaseous molecules can be determined. Pt is closely allied to Ir, and less closely to Os, in its chemical properties. It is distinctly metallic physically, and, on the whole, chemically also. PtO_2 is both basic and acidic; Pt forms numerous acids by combining with H and negative radicles such as Cl_6, $(NO_2)_4Cl_2$, $(CN)_4$, $(SCN)_6$, &c. For a fuller account of the chemical relations of Pt *v.* NOBLE METALS, vol. iii. p. 628, and *cf.* IRON GROUP OF ELEMENTS, vol. iii. p. 67.

Pt is used for making crucibles &c. for laboratory use, and vessels for evaporating conc. oil of vitriol, &c. Apparatus is sometimes platinised by placing in hot $PtCl_4Aq$ containing KOH and some organic reducing compound.

Reactions and Combinations.—1. Is *not* acted on by *oxygen*; concerning absorption of O by Pt *v. Properties.*—2. Heated to redness with *sulphur*, in presence of borax, PtS is formed (Deville a. Debray, *C. R.* 89, 587).—3. Said to form a compound by heating Pt black with *selenion.*—4. With *chlorine*, *bromine*, and *iodine* Pt reacts at temperatures above c. 300° (Langer a. Meyer, *Pyrochemische Untersuchungen* [Braunschweig, 1885] 44, 57). Cl and Br attack Pt in presence of water.—5. Scarcely acted on by *fluorine* below 100° (Moissan, *A. Ch.* 1892. 125). 6. *Hydrogen* is occluded by Pt; a considerable quantity of heat is produced, and perhaps compounds are formed (*v.* PLATINUM HYDRIDE, p.

290).—7. Heated with *arsenic*, a compound $PtAs_2$ is said to be formed (*v. Gm.-K.* 3, 1192–1193).—8. *Phosphorus* combines when heated with finely-divided Pt (Schrötter, *J.* 1849. 246). 9. A boride is formed by heating Pt black with amorphous *boron* (Descotils, *A. Ch.* [3] 67, 88; Deville a. Wöhler, *J.* 1856. 279).—10. Heated to whiteness with *silicon*, Pt forms several compounds; also combines with Si when heated with *silica and carbon* (*v.* PLATINUM SILICIDES, p. 291).—11. Softens when heated with *carbon* (*v.* PLATINUM CARBIDE, p. 289).—12. Alloys with many of the more easily fusible *metals* (*v.* PLATINUM ALLOYS, *infra*).—13. Pt is not acted on by pure *hydrochloric*, *nitric*, or *sulphuric acid* (Scheurer-Kestner, *C. R.* 86, 1082; 91, 59). It dissolves in warm *aqua regia*, forming $PtCl_4$ (*v.* Dullo, *J. pr.* 78, 369). Alloying modifies the solubility in acids; alloys of Pt with small quantities of Ir or Rh are scarcely sol. in *aqua regia*, while an alloy with much Ag dissolves in conc. HNO_3Aq; Pt ppd. by zinc dissolves in conc. HNO_3Aq (*v.* Winkler, *Fr.* 13, 369; van Riemsdyk, *B.* 16, 387; Wilm, *B.* 13, 1198).—14. *Conc. sulphuric acid containing a little nitrous acid* dissolves small quantities of Pt (Scheurer-Kestner, *C. R.* 86, 1082; 91, 59). *Nitric acid, containing bromine or bromhydric acid*, and also *hydrochloric acid, into which chlorine is passed*, dissolve Pt, forming $PtBr_4$ and $PtCl_4$ respectively (Wagner, *W. J.* 1876. 149; Seubert, *A.* 207, 16).—15. Pt is acted on, at red heat, by *molten alkalis*, *baryta*, *nitrates*, *potassium cyanide*, and by a mixture of *alkali carbonate and sulphur*.—16. $PtCl_2$ or $PtBr_2$ and PtI_2 are formed when Pt wire is heated in *iodine mono-* or *tri-chloride*, or in *chlorine mixed with iodine or iodine bromide*; with *phosphorus pentachloride* Pt phosphide is formed; with *carbon tetrachloride* C, C_2Cl_6, and Cl are produced; *hydrogen chloride* forms $PtCl_2$; *hydrogen fluoride* produces a soluble Pt salt; and with *mercurous chloride* Hg and $PtCl_2$ are obtained (Hodgkinson a. Lowndes, *C. N.* 58, 223).

Platinum, acids of. The hydroxide $Pt(OH)_4$ reacts with strong bases as an acid. Several acids have been isolated containing Pt in combination with more or less complex negative radicles; these are H_2PtCl_4, H_2PtCl_6, H_2PtBr_6, H_2PtI_6; $H_2Pt(NO_2)_4$, $H_4Pt_3O(NO_2)_8$; H_2PtCy_4, $H_2PtCy_4Cl_2$, $H_2Pt(SCN)_6$; $H_2Pt_4S_6$; $Pt(NH_3)_2.Cl.SO_3H$; $PtCl_2.P(OH)_3$. These acids are described as *platino-* and *platini-chlorhydric acid*, &c. (pp. 283 and 282); *platino-nitrous acid*, &c. (p. 284); *platino-cyanhydric acid*, &c. (vol. ii. pp. 344–5); *thioplatinic acid* (p. 281); *platosammine-chloro-sulphonic acid* (p. 293); *platino-chloro-phosphoric acid* (p. 284).

Platinum, alloys of. Pt alloys with many metals by fusing it with them; with Sb, As, Pb, Sn, and Zn heat and light are produced. Alloys which seem to be definite compounds have been obtained with *arsenic* ($PtAs_2$, Gehlen, *Gm.-K.* 3, 1192); *antimony* ($PtSb_2$, Christofle); *cadmium* ($PtCd_2$, Deville a. Debray, *A. Ch.* [3] 56, 385); *lead* (PtPb, Bauer, *B.* 3, 836; 4, 449; D. a. D., *C. R.* 90, 1195); *tin* (Pt_2Sn_3, $PtSn_4$, and Pt_4Sn_3, D. a. D., *A. Ch.* [3] 56, 385; Debray, *C. R.* 104, 1470); and *zinc* (Pt_2Zn_3, D. a. D., *l.c.*). Alloys have also been formed with *bismuth* (Gehlen, *Gm.-K.* 3, 1192); *copper* (D. a. D., *A. Ch.* 1859. 611; Hélonis, *B.* 6, 42); *gold* (Dodé, *B.* 6, 1278); *iridium* (D. a. D., *A. Ch.* [3] 56, 385; Pelouze, *C. R.* 49, 896; Matthey, *Pr.* 28, 463; D. a. D., *C. R.* 81, 839; Morin, *C. R.* 78, 1502); *iron* (D. a. D., *C. R.* 89, 587; Daubrée, *C. R.* 80, 526); *nickel* (Hélonis, *B.* 6, 42); *potassium* (V. Meyer, *B.* 13, 392); *silver* (D. a. D., *A. Ch.* 1859. 611; H., *l.c.*); *sodium* (V. M., *l.c.*).

Amalgams of platinum. According to Crafts (*Bl.* [2] 49, 856), Hg has no action on Pt at the ordinary temperature, but Pt dissolves to a very small extent in boiling Hg, air being excluded. When acid is present Hg alloys with Pt (Casamajor, *Am.* 6, 540; Skey, *C. N.* 22, 282; Krouchkoll, *J. de Ph.* [3] 3, 139). The amalgams are most easily formed by adding sodium-amalgam to $PtCl_4Aq$; with 13·5 p.c. Pt the amalgam is a thick liquid; with 25·8 p.c. Pt it is solid; an amalgam with c. 30 p.c. Pt has also been obtained (Joule, *C. J.* [2] 1, 378).

Platinum, antimonide of. An alloy of Pt and Sb, approximating to the composition $PtSb_2$, is obtained by melting the elements together in the ratio Pt : 2Sb; also by passing SbH_3 into H_2PtCl_6Aq, and removing ppd. Sb and $PtCl_2$ by washing with K_2SAq and KCNAq mixed (Christofle, *Recherches sur les Combin. de l'Antimoine*, Göttingen, 1863).

Platinum, arsenides of. An alloy $PtAs_2$ is said to be formed by heating Pt black with As (Gehlen, *Gm.-K.* 3, 1192). By passing AsH_3 into $PtCl_4Aq$, and heating the pp. in dry CO_2, Pt_3As_2 is said to be formed (Tivoli, *G.* 1885. 487).

Platinum-arsenic hydroxide. According to Tivoli (*G.* 1885. 487) a compound PtAsOH is produced by passing AsH_3, containing H but no other impurity, into $PtCl_4Aq$ (corresponding with 2 g. Pt in 60 c.c. water), and drying the black flocculent pp. at 120°–130°. The compound is decomposed by washing with alcohol or water; hot conc. H_2SO_4 at once separates Pt; heating in dry CO_2 produces As_2O_3, Pt_3As_2, and H_2O. Gibbs (*Am.* 8, 289) described some compounds of Pt and As_2O_3.

Platinum, boride of. Pt and B combine when melted together (Descotils, *A. Ch.* [3] 67, 88). It is best to heat Pt black and amorphous B under borax (Wöhler a. Debray, *A.* 101, 113). When excess of B is used, a crystalline compound containing 91·8 p.c. Pt., S.G. 17·3, is formed (Martius, *A.* 109, 79).

Platinum, bromides of. Pt and Br combine when heated together to above 300° (Langer a. Meyer, *Pyrochemische Untersuchungen* [Braunschweig, 1885], pp. 44, 57). Two bromides are known, $PtBr_2$ and $PtBr_4$; the V.D. of neither has been determined.

PLATINUM DIBROMIDE $PtBr_2$ (*Platinous bromide.*) Formed by heating HBrAq, b.p. 126°, with Br and spongy Pt to 180° in a sealed tube—$H_2PtBr_6.xH_2O$ is thus formed—evaporating to dryness, heating to c. 200°, and washing the residue with boiling water (Topsoë, *J.* 1868. 273). Pullinger (*C. J.* 59, 602) heats spongy Pt with Br and HBrAq in a flask with a reflux-condenser, evaporates to dryness, and heats the residue to c. 280°. $PtBr_2$ is a brown powder; decomposes slowly at c. 300° in an air-current (P., *l.c.*); insol. water, sol. HBrAq and KBrAq. With KBr forms K_2PtBr_4 (*v.* PLATINO-BROMIDES,

p. 282). **Combines with CO at c. 180° to form $PtBr_2.CO$, a bright red, crystalline solid; melts at 177·7°; not very hygroscopic; sol. alcohol; decomposed by water (Pullinger, *l.c.*). This compound is called by P. *carbonyl-bromoplatinite*.**

PLATINUM TETRABROMIDE $PtBr_4$ (*Platinic bromide*). Formed by heating spongy Pt with Br and HBrAq in a sealed tube to 180°—or by boiling Br, Pt, and HBrAq in flask with reflux-condenser (Pullinger, *C. J.* 59, 602)—filtering, evaporating, heating residue at 180° till HBr ceases to come off; treating with boiling water, filtering from traces of $PtBr_2$, evaporating, and drying at 180° (H. Meyer a. Züblin, *B.* 13, 404; Halberstadt, *B.* 17, 2963). A dark-brown, non-hygroscopic powder; sol. aqueous alcohol, more sol. absolute alcohol or ether, v. sl. sol. water (S. at 20° = ·41) (H. *l.c.*); somewhat sol. glycerin. Pt black separates when solution in alcohol, ether, or glycerin is heated. With HBr forms H_2PtBr_6 (*v.* PLATINI-BROMHYDRIC ACID, p. 282). With many metallic bromides forms salts $M_2^IPtBr_6$ (*v.* PLATINI-BROMIDES, p. 282). When spongy Pt is heated with HBrAq and excess of HNO_3, small, dark-brown, very hygroscopic crystals of *platinum nitrosyl bromide*, $PtBr_4.2NOBr$, are obtained (Topsoë, *J.* 1868. 273).

Platinum, carbide of. Pt becomes brittle and more friable when heated to redness with charcoal. By heating the compound which $PtCl_4$ forms with acetone, Zeise (*J. pr.* 20, 209) obtained a black solid, to which he gave the composition PtC_2.

Platinum, chlorides of. Two chlorides of Pt are known, $PtCl_2$ and $PtCl_4$. When Pt black is heated in dry Cl at 240°–250°, $PtCl_2$ is formed, according to Schützenberger (*C. R.* 70, 1134, 1287). Pigeon (*C. R.* 108, 1009) says that at 360° $PtCl_2$ and $PtCl_4$ are formed, but the action is incomplete. Troost a. Hautefeuille (*C. R.* 84, 94) found that $PtCl_2$ was formed when Pt was heated in Cl to 1400°, and the tube was suddenly cooled.

PLATINUM DICHLORIDE $PtCl_2$ (*Platinous chloride. Platinochloride*). V.D. not determined.

Formation.—1. By heating H_2PtCl_6 to c. 230° (Berzelius, *Gm.-K.* 3, 1081).—2. By heating Pt black in Cl at 240°–250° till no more Cl is taken up (Schützenberger, *C. R.* 70, 1134, 1287).—3. By decomposing $Na_2Pt(NaSO_3)_4$ by HClAq (Liebig, *A.* 23, 23; for formation of $Na_2Pt(NaSO_3)_4$ *v.* PLATINOSULPHONATES, p. 285).—4. A solution of $PtCl_2$ is obtained by passing SO_2 into $PtCl_4Aq$ till the liquid becomes red.

Preparation.—1. H_2PtCl_6Aq is evaporated to dryness, and the residue is heated in a bath of molten tin, *i.e.* at c. 230°, with constant stirring as long as Cl is given off (Berzelius, *Gm.-K.* 3, 1081). Or the heating is stopped before much of the solid is decomposed, the residue is dissolved in water, the dark-brown opaque liquid is evaporated, and the $PtCl_2$ which separates is dried at c. 150° (*cf.* Magnus, *P.* 14, 239).—2. $H_2PtCl_6.6H_2O$ is heated *in vacuo*, in presence of molten KOH, at 100° for 2 or 3 days; the temperature is then raised to 360°, and maintained thereat so long as Cl is given off (Pigeon, *C. R.* 112, 1218). Shenstone a. Beck (*C. J.* 61, 445) say that $PtCl_2$, prepared as directed above, always contains small quantities of some basic compound; and that when the salt is strongly heated small quantities of HCl and O are obtained, as well as Cl. Shenstone (*C. J. Proc.* 1892 93. 38) finds that $PtCl_2$ almost free from basic compounds can be prepared by heating $PtCl_4$ in a stream of dry HCl; a sample prepared in this way gave only ·15 p.c. of HCl and O when decomposed by heat.

Properties and Reactions.—A brown powder; S.G. 5·87 at 11° (Bödeker). H.F. $[Pt,Cl^2] = 22,600$ (Berthelot, *C. R.* 87, 615). Insol. water, sol. HClAq in absence of air. Decomposed by heating to redness, giving off all Cl, and leaving Pt. According to Shenstone a. Beck (*v. Preparation*), the Cl thus obtained contains a little HCl and O, and H_2O is also given off. Not acted on by HNO_3Aq or dilute H_2SO_4Aq; decomposed by KOHAq, giving $Pt(OH)_2$; by heating with conc. H_2SO_4, and then with water, Kane obtained a black powder to which he gave the composition $PtCl_2.3PtO$ (*B. J.* 24, 238).

Combinations.—$PtCl_2$ combines with many metallic chlorides; the compounds are described as *platino-chlorides* (p. 284). With HCl an acid H_2PtCl_4 is formed (*v.* PLATINO-CHLORHYDRIC ACID, p. 283). With CO the compounds $PtCl_2.CO$, $PtCl_2.2CO$, and $2PtCl_2.3CO$ are formed. These compounds are produced by passing alternate currents of Cl and CO over spongy Pt at 250° (Schützenberger, *A. Ch.* [4] 21, 350). Pullinger (*C. J.* 59, 598) found that a fourth compound is also formed—$PtCl_2.2COCl_2$ (or $PtCl_4.2CO$). *Carbonyl chloroplatinite* ($PtCl_2.CO$) combines with HCl, and with various hydrochlorides of organic bases (*v.* Mylius a. Förster, *B.* 24, 2424). $PtCl_2$ combines with PCl_3 to form $PtCl_2.PCl_3$ and $PtCl_2.2PCl_3$; and from these is derived a number of complex bodies. By treating $PtCl_2.PCl_3$ with H_2O an acid $PtCl_2.P(OH)_3$ is obtained, from which various salt-like compounds are derived; similarly $PtCl_2.2PCl_3$ yields an acid $PtCl_2.P_2(OH)_6$, and this gives many salt-like derivatives (Schützenberger, *A. Ch.* [4] 15, 100; 21, 350; Baudrimont, *C. R.* 53, 637: *cf.* PLATINO-CHLOROPHOSPHATES, p. 284). By heating $PtCl_2.PCl_3$ with $PtCl_2$ Colchin (*C. R.* 86, 1402) obtained $2PtCl_2.PCl_3$. For ammoniacal derivatives of the platino-phosphorus chlorides *v.* Colchin (*l.c.*) and Quesneville (*M. S.* [3] 6, 659), also Schützenberger (*Bl.* [2] 14, 97; 17, 482; 18, 101, 148).

PLATINUM TETRACHLORIDE $PtCl_4$ (*Platinic chloride. Platinichloride*). V.D. not determined.

Formation.—1. By heating Pt in Cl to c. 1700° (Langer a. Meyer, *l.c.* 44, 57); if a thin wire of Pt is heated by an electric current nearly to melting, in a stream of Cl, $PtCl_4$ is formed (Hodgkinson a. Lowndes, *C. N.* 58, 158, 223).—2. By allowing $H_2PtCl_6.6H_2O$ to remain over KOH, when it loses $4H_2O$, and then heating in Cl to c. 350° (Pigeon, *C. R.* 110, 77).—3. By heating Pt and Se, mixed with $AsCl_3$, in Cl (*v. Preparation*).—4. $PtCl_4.5H_2O$ is obtained by adding $AgNO_3Aq$ to H_2PtCl_6Aq in the ratio of $H_2PtCl_6:2AgNO_3$, heating, filtering from AgCl, and evaporating finally over H_2SO_4 (Norton, *J. pr.* [2] 2, 469; 5, 365; Engel, *Bl.* [2] 50, 100; Quesneville, *M. S.* [3] 6, 659).

Preparation.—1. Spongy Pt is mixed with rather less than its own weight of Se, the mixture is placed in a tube of hard glass filled to one-third with $AsCl_3$, and heated in a stream of Cl till the mass liquefies and boils, when the tube is sealed and heated for some hours at 250°; on cooling, the colourless crystals are separated from the pale-yellow crystals and the yellow liquid, and are heated *in vacuo* at 110°, whereby $PtCl_4$ and $SeCl_4$ remain; this residue is then heated at 360° in a stream of Cl, when $SeCl_4$ sublimes and $PtCl_4$ remains (Pigeon, *C. R.* 108, 1009).—2. Dry H_2PtCl_6 is placed in a porcelain boat which is heated, in a tube of hard glass, to 165° for about 15 hours in a stream of dry HCl (Pullinger, *C. J.* 61, 422).

Properties and Reactions. — H.F. $[Pt,Cl^4] = 59,800$; $[Pt,Cl^4,Aq] = 79,400$ (Pigeon, *C. R.* 110, 77; 112, 791). A brown solid, said by Pigeon to be deliquescent; described by Pullinger as very soluble in water, but not deliquescent. The hydrate (*v. Formation*, No. 4) forms large, red, monoclinic crystals; according to Norton this compound has $5H_2O$, according to Engel $4H_2O$; all H_2O except one molecule is removed at 100°, but the last molecule is not removable without decomposition. Decomposed by heating to dull redness (Pigeon, *C. R.* 110, 77); in presence of Cl, may be heated to c. 360°; in dry HCl slight decomposition occurs at c. 200° (Pullinger, *l.c.*). HClAq produces H_2PtCl_6Aq; NH_4Cl ppts. $(NH_4)_2PtCl_6$. $AgNO_3Aq$ ppts. Ag_2PtCl_6 from cold $PtCl_4Aq$, but on heating AgCl is formed and $PtCl_4$ goes into solution (Jörgensen, *J. pr.* [2] 16, 345). Pigeon (*C. R.* 112, 791) gives $[Ag^2PtCl^6,Aq] = 12,160$, to form $PtCl_4Aq$ and 2AgCl; $PtCl_4Aq$ is decomposed by light, for some measurements *v.* Foussereau (*C. R.* 103, 248).

Combinations.—1. With *water* (*v. Formation*, No. 4, and *Properties*). — 2. With *hydrogen chloride* to form $H_2PtCl_6.6H_2O$; the compound $HPtCl_5.2H_2O$ was obtained by Pigeon by heating $H_2PtCl_6.6H_2O$ *in vacuo* at 100° (*v.* PLATINICHLORHYDRIC ACID, p. 282). Pigeon (*C. R.* 110, 77) gives $[PtCl^4,2HClAq] = 24,800$. — 3. With many *metallic chlorides* to form *platinichlorides* (*q. v.*, p. 282).—4. A compound with *phosphorous chloride* $PtCl_4.PCl_3$ is formed by treating $PtCl_2.PCl_3$ with Cl (Schützenberger, *Bl.* [2] 14, 97; 17, 482; 18, 101, 148; *cf.* Baudrimont, *C. R.* 53, 637).—5. A compound with *nitrosyl chloride*, $PtCl_4.2NOCl.H_2O$, is one of the products of the action of fuming HNO_3 on H_2PtCl_6Aq (Weber, *P.* 131, 441).—6. Combines with *alcohol*, and with *ethyl sulphide*, to form $PtCl_4.2C_2H_6O$ and $PtCl_4.2(Et)_2S$ respectively (Schützenberger, *C. R.* 70, 1134; Blomstrand, *J. pr.* [2] 17, 189).—7. Compounds with various *organic bases and metallic chlorides*, $EtNH_2$, &c., are described by Jörgensen (*J. pr.* [2] 33, 409).

Platinum, chloro-iodides of; *v.* PLATINUM IODOCHLORIDES, *infra*.

Platinum, cyanides of; *and derivatives*: *v.* vol. ii. p. 343.

Platinum, fluoride of. Only one fluoride of Pt has been isolated, PtF_4. Prepared by heating Pt wire in F, in a Pt or fluorspar tube, to c. 500°; if HF is mixed with the F combination occurs at the ordinary temperature (Moissan, *C. R.* 109, 807). Small buff-coloured crystals, or fused masses of a deep red colour. Dissolves in a little water, forming fawn-coloured solution, which almost at once decomposes, with rise of temperature and production of $PtO_2.xH_2O$ and HFAq. Heated to bright redness in Pt tube, PtF_4 is decomposed to F, and Pt which separates in crystals. A compound with PF_3, viz. $PtF_4.2PF_3$, is formed by passing PF_5 over spongy Pt heated to dull redness (M., *Bl.* [3] 5, 454). The decomposing action of H_2O on PtF_4 explains the failure of former attempts to prepare a fluoride of Pt in the wet way.

Platinum-iridium, or *platin-iridium*. An alloy of Pt and Ir which remains, mixed with osm-iridium, when many samples of Pt ore are heated with *aqua regia* (*cf.* IRIDIUM, vol. iii. p. 46).

Platinum, hydride of. Pt black absorbs considerable quantities of H. According to Berthelot (*A. Ch.* [5] 30, 519), the relative weights of Pt and H are approximately 15:1 and 10:1; a considerable quantity of heat is produced. No certain evidence of the formation of hydrides has been obtained; but Thoma's result (*Z. P. C.* 3, 69), that the excess of H, above a definite quantity, absorbed by Pt when Pt is the negative electrode during the electrolysis of dilute sulphuric acid, is not easily given up, indicates the probable existence of a compound or compounds (*cf.* PALLADIUM, vol. ii. p. 720).

Platinum, hydroxides of; *v.* PLATINUM, OXIDES AND HYDROXIDES OF, p. 291.

Platinum, iodides of. Pt and I combine directly to form PtI_4; the lower iodide PtI_2 has also been obtained, but not pure.

PLATINUM DI-IODIDE PtI_2 (*Platinous iodide. Platino-iodide*). This compound is described as a black, heavy powder, insol. water, alcohol, and acids; giving Pt and I at 300°-350°; decomposed by NaOHAq to PtO_2H_2. It is produced by boiling $PtCl_2$ with fairly conc. KIAq (Lassaigne, *A. Ch.* [2] 51, 113); but it has not been obtained pure (Clementi, *J.* 1858. 420; Topsoë, *Ar. Sc.* 38, 297). The compound $PtI_2.CO$, *carbonyl iodoplatinite*, is described by Mylius a. Förster (*B.* 24, 2424).

PLATINUM TETRA-IODIDE PtI_4 (*Platinic iodide. Platini-iodide*). V.D. not determined. Prepared by heating PtO_2 with HIAq (Clementi, *J.* 1855. 420); also by the action of cold HIAq on $H_2PtCl_6.6H_2O$ (Topsoë, *Ar. Sc.* 38, 297), and evaporating. Pullinger (*C. J.* 59, 602) obtained PtI_4 by dissolving spongy Pt in a hot solution of I in HIAq, evaporating to dryness, heating to 180°, and washing with water. A brown-black amorphous powder, insol. water; sol. HIAq and metallic iodide solutions (Topsoë, *l.c.*); not wholly decomposed by heating with Na_2CO_3 to the m.p. of the carbonate (Pullinger, *l.c.*). Combines with HI to form $H_2PtI_6.9H_2O$ (*v.* PLATINI-IODHYDRIC ACID, p. 283), and with metallic iodides to form salts (*v.* PLATINI-IODIDES, p. 283).

Platinum, iodochlorides of. A compound PtI_2Cl_2 is said to be formed, in large red plates, by dissolving Pt and I in *aqua regia* and evaporating at 100° (Kämmerer, *A.* 148, 329). Another compound PtI_3Cl was obtained by Mather, as a black powder, by evaporating H_2PtCl_6 with a small excess of HIAq, and heating the residue to 150° (*Am. S.* 27, 257).

Platinum-nitrosyl bromide and Platinum-nitrosyl chloride, *v.* PLATINUM TETRABROMIDE,

p. 289; and Platinum tetrachloride, *Combinations*, No. 5, p. 290.

Platinum, oxides and hydroxides of. Three oxides have been isolated; PtO, Pt_3O_4, and PtO_2; hydrates of all are known. PtO forms a few salts; it also dissolves in molten KOH and $NaOH$. PtO_2 forms corresponding salts, and also combines with alkaline oxides to form *platinates* (*q.v.* p. 281).

Platinum monoxide PtO (*Platinous oxide*). Obtained as a violet powder, by strongly heating the pp. formed by $CaOAq$ acting on H_2PtCl_6Aq in sunlight, and washing with water and then with HNO_3Aq (Döbereiner, *P.* 28, 181). Also by carefully heating PtO_2H_2. Reduced to Pt at red heat, also by action of reducers such as HCO_2HAq. Dissolves in molten KOH and $NaOH$, but the compounds thus formed have not been examined. A compound which is perhaps $PtO.CO$ is described by Mylius a. Förster (*B.* 24, 2440).

Platinous hydroxide PtO_2H_2 was obtained by Thomsen (*J. pr.* [2] 15, 294) by adding $NaOHAq$ to K_2PtCl_4Aq (1:12) in the ratio $2NaOH{:}K_2PtCl_4$, and heating to boiling. A black powder, sol. $HClAq$, $HBrAq$, and SO_2Aq, forming corresponding salts. Freshly ppd. PtO_2H_2 dissolves in excess of $NaOHAq$.

Tri-platinum tetroxide Pt_3O_4 (*Platino-platinic oxide*). A black powder, insol. acids; obtained by heating dehydrated Na_2PtCl_6 with 4 parts dry Na_2CO_3 till fusion begins, boiling with water, then with dilute HNO_3Aq, and finally with *aqua regia* (Jörgensen, *J. pr.* [2] 16, 344). Loses its O at red heat; easily reduced to Pt by H or coal-gas, even without heating. Prost (*Bl.* [2] 46, 156) describes a hydrate $Pt_3O_4.9H_2O$.

Platinum dioxide PtO_2 (*Platinic oxide*). A black powder, obtained by gently heating PtO_4H_4. PtO_2 is insol. acids, but salts of this oxide are formed from the hydroxide.

Platinic hydroxide PtO_4H_4. Formed by boiling $PtCl_4Aq$ for a considerable time with a large excess of $NaOHAq$, acidifying by acetic acid, drying the white flocculent pp. in the air, and heating the yellow hydrate, $PtO_4H_4.2H_2O$, to 100° (Topsoë, *B.* 3, 462; Fremy, *A. Ch.* [3] 31, 478). Also obtained by evaporating H_2PtCl_6Aq with excess of Na_2CO_3, rubbing up the residue in water, and treating with acetic acid (Döbereiner, *P.* 28, 181; Topsoë, *l.c.*; *cf.* Wittstein, *R. P.* 74, 43). A hydrate $PtO_4H_4.H_2O$ was obtained by Prost (*Bl.* [2] 46, 156) by adding water to a solution of PtO_4H_4 in conc. HNO_3Aq. A reddish-brown powder; dehydrated by heating gently; at a higher temperature gives Pt and O. Heated in H gives Pt. Sol. $NaOHAq$, $HClAq$, HNO_3Aq, and H_2SO_4Aq. With acids forms platinic salts, PtX_4, where $X = \frac{1}{2}SO_4$, $\frac{1}{2}CO_3$, NO_3, &c.; with strongly basic oxides forms platinates, $PtO_2.xMO$ (*v.* Platinates, p. 281). Compounds with SnO and SnO_2 are described by Delachanel a. Mermet (*C. R.* 81, 370), Schneider (*P.* 136, 105), Lévy a. Bourgeois (*C. R.* 94, 1365), and Schützenberger (*C. R.* 98, 985). PtO_4H_4 dissolves in solutions of certain molybdates and tungstates, forming *platini-molybdates* and *platini-tungstates* (*q.v.* p. 283).

Platinum, oxychlorides of. When $AgNO_3Aq$ is added to $PtCl_4Aq$ in the ratio $PtCl_4{:}2AgNO_3$, or when $AgNO_3Aq$ and H_2PtCl_6Aq are heated together in the ratio $H_2PtCl_6{:}4AgNO_3$, a pp. is obtained which has the empirical composition $PtCl_2(OH)_2.2AgCl$; this substance may be regarded as a compound of the hydrated oxychloride $PtOCl_2.H_2O$ (Jörgensen, *J. pr.* [2] 16, 345). The pps. formed by $CaOAq$ and $BaOAq$ in $PtCl_4Aq$ are supposed to contain oxychlorides of Pt (*v.* Johannsen, *A.* 155, 204).

Platinum, oxysulphide of, $2PtOS.H_2O$. PtS_2 slowly oxidises by exposure to air; by washing the product (to dissolve H_2SO_4 and SO_2) and drying in a stream of CO_2, a black powder is obtained having the composition $2PtOS.H_2O$ (perhaps $HO.PtS.O.SPt.OH$). This substance is an energetic oxidiser; H, CO, H_2S, SO_2 take fire when brought into contact with it; NH_3 is absorbed and oxidised to HNO_2 and HNO_3 (E. von Meyer, *J. pr.* [2] 15, 1).

Platinum, phosphides of. Pt and P combine when strongly heated together. Schrötter obtained a grey metal-like mass, S.G. 8·77, to which he gave the composition PtP_2, by heating Pt black in vapour of P (*J.* 1879. 246). By heating Pt and P to white heat, Clarke a. Joslin (*Am.* 5, 231) obtained Pt_3P_5; and by heating in a muffle they got Pt_2P, sol. *aqua regia* but changed to insoluble PtP.

Platinum, salts of. But few salts, excepting the halides, are known wherein Pt replaces the H of acids; Pt more frequently enters into the acid radicle, than the positive radicle, of salts.

Platinum, selenide of. By heating Pt and Se, Berzelius obtained a grey, infusible powder; perhaps $PtSe$ (*Gm.-K.* 3, 1081).

Platinum, selenocyanides of; for a double salt *v.* vol. ii. p. 348.

Platinum, silicides of. A white, crystalline, brittle solid, Pt_4Si_3, was obtained by Guyard (*Bl.* [2] 25, 510) by heating together equal parts of Pt black and powdered crystalline Si (*cf.* Winkler, *J. pr.* 91, 203). According to Miles (*Am.* 8, 428), the conditions favourable to the formation of compounds of Pt and Si are a high temperature, the presence of a reducer such as CO, a basic substance such as MgO, and SiF_4, in contact with Pt (*v.* also Brown, *Am.* 7, 173).

Platinum, sulphides of. Pt and S combine when heated together. Two sulphides have been isolated, PtS and PtS_2; there is also evidence of the existence of Pt_2S_3.

Platinum monosulphide PtS (*Platinous sulphide*). Obtained by heating Pt black and S, and volatilising excess of S, in absence of air; also by heating $(NH_4)_2PtCl_6$ with S, out of contact with air, till NH_4Cl and excess of S are volatilised; also by passing H_2S into $PtCl_2Aq$ (Berzelius). Prepared in crystals by heating to redness a mixture of 1 pt. Pt, 1 pt. borax, and 10 pts. pyrites (Deville a. Debray, *A. Ch.* [2] 55, 215). A grey, lustrous solid; S.G. 6·2. PtS prepared in the wet way is a black powder. Unchanged in air, even when moist; unacted on by boiling acids; loses S when heated in air, leaving Pt; reduction in H begins at 19°. A compound with CO—$PtS.CO$—was obtained by Mylius a. Förster (*B.* 24, 2438) by the action of H_2S on $PtCl_2.CO$.

Platinum disulphide PtS_2 (*Platinic sulphide*). Obtained by passing H_2S into Na_2PtCl_6Aq, or by dropping H_2PtCl_6Aq into solution of an alkali hydrosulphide. Also formed by digesting, in a strong closed flask, 1 pt. $PtCl_4$, 4 pts. alcohol, and 5 pts. CS_2 (Böttger, *J. pr.* 3, 274); and by decolourising H_2PtCl_6Aq by SO_2, and then heating in a sealed tube at 200° (Geitner, *A.* 129, 358). PtS_2 is also a product of the action of HClAq in air on $Na_4Pt_3S_6$ or $H_2Pt_4S_6$ (*v.* THIOPLATINATES, p. 281). Colloidal soluble PtS_2 was obtained by Winssinger (*Bl.* [2] 49, 452) by passing H_2S into very dilute $PtCl_4Aq$, and dialysing. A black solid; as obtained from $Na_4Pt_3S_6$ forms steel-grey needles, S.G. 5·27. PtS_2 prepared by one of the wet methods must be dried in absence of air, else it is partially decomposed. Heated out of air forms PtS, and Pt and S. Oxidised to sulphate by strong oxidisers, such as *aqua regia*, Cl, fuming HNO_3, molten $KClO_3$ or KNO_3. Freshly ppd. PtS_2 dissolves in alkali sulphide solutions forming *thioplatinates* (*q. v.*), from which solutions it is reppd. by acids. Clässon (*J. pr.* [2] 15, 193) describes a compound with EtSH.

PLATINUM SESQUISULPHIDE, Pt_2S_3. This compound is said to be formed, as a steel-grey, metal-like solid, S.G. 5·52, by the oxidation in air of $H_2Pt_4S_6$ (Schneider, *P.* 136, 105; 138, 604; 139, 661; 141, 519; 148, 633; 149, 381). Schneider also describes a compound $4PtS.PtS_2 = Pt_5S_6$.

Platinum, sulphocyanides of; *v.* vol. ii. p. 357; *v.* also Guareschi, *Giorn. della R. Accad. di Med.* 1891. No. 5; abstract in *B.* 25, *Ref.* 7.

Platinum, thiocarbide of. Pt_2CS_2. This compound is described by Schützenberger (*C. R.* 111, 391). It is a black powder; obtained by passing a stream of N, or H, charged with CS_2, over spongy Pt heated to 400°–450°.

M. M. P. M.

PLATINUM-AMMONIUM COMPOUNDS (*Ammonio-platinum compounds. Ammoniacal platinum bases. Platinammines*). When a solution of $PtCl_2$ in HClAq reacts with NH_3, more than one compound of the form $PtCl_2.2NH_3$ is obtained. These compounds react with acids, oxidisers, &c., to form many derivatives containing Pt, N, H, and negative radicles, in which the reactions of Pt and NH_3 are more or less modified.

The platin-ammonium compounds may be regarded as salts of bases derived from two or more NH_4 groups, in which part of the H is replaced by Pt; thus $PtCl_2.2NH_3$ may be called platoso-diammonium chloride, and formulated as $N_2H_6Pt.Cl_2$. Similarly $PtCl_2.4NH_3$ may be regarded as $Pt\left\langle\begin{array}{l}NH_2(NH_4)Cl\\NH_2(NH_4)Cl\end{array}\right.$, and called ammonium platoso-diammonium chloride. The compounds derived from $PtCl_4$ are regarded, in this scheme, as platini-ammonium compounds; thus, $PtCl_4.2NH_3$ is $Cl_2Pt.NH_2.NH_4.Cl_2$ (*v.* Hofmann, *T.* 1851. [2] 357; Weltzien, *A.* 97, 19; Kolbe, *J. pr.* [2] 2, 217; Grimm, *A.* 99, 67).

This view of the constitution of the compounds in question was opposed by Claus (*J. pr.* 63, 99), Blomstrand (*B.* 4, 40, 639, 673; 6, 1469), Jörgensen (*J. pr.* [2] 33, 489), and others. Jörgensen found that pyridine, $N.C_5H_5$, forms a compound with platinous chloride similar to $PtCl_2.4NH_3$; in this pyridine compound, which has the composition $PtCl_2.4NC_5H_5$, the atoms of hydrogen cannot be in direct union with N; for the constitution of pyridine is known to be 
. Now if the ammoniacal platinum bases are all to be derived from NH_4, by substituting H by NH_4 groups, it is evident that the substituted H atoms must always be directly bound to N atoms. But the existence of the pyridine compound shows that this is not necessary. Hence $PtCl_2.4NH_3$ may be regarded as $Pt\left\langle\begin{array}{l}NH_3.NH_3Cl\\NH_3.NH_3Cl\end{array}\right.$.

The classification and nomenclature of the platin-ammonium compounds proposed by Blomstrand (*Chemie der Jetztzeit*, Heidelberg, 1869; *B.* 2, 202; 4, 40, 639, 673; 6, 1469) is now usually adopted. In the following formulæ R stands for a monovalent negative radicle. Blomstrand uses the term *ammine* to distinguish these compounds from the *amines*, which contain the group NH_2.

Class I. PLATO- OR PLATOSO- COMPOUNDS.

Series 1. *Platosemiammines*, $RPtNH_3R$.
" 2. *Platosammines*, $Pt(NH_3R)_2$.
" 3. *Platodiammines*, $Pt(NH_3.NH_3R)_2$.
" 4. *Platosemidiammines*, $Pt(NH_3.NH_3R)R$.
" 5. *Platomonodiammines*, $Pt(NH_3.NH_3R)(NH_3R)$.

Series 2 and 4 are isomeric. Cleve has isolated two distinct aniline compounds, $Pt(NH_3)_2.(C_6H_5NH_2)_2.R_2$ (*cf.* Jörgensen, *J. pr.* [2] 33, 489).

Class II. PLATINI- OR PLATIN- COMPOUNDS.

Series 1. *Platinammines*, $R_2Pt(NH_3R)_2$.
" 2. *Platinidiammines*, $R_2Pt(NH_3.NH_3R)_2$.
" 3. *Platinisemidiammines*, $R_2Pt(NH_3.NH_3R)R$.
" 4. *Platinimonodiammines*, $R_2Pt(NH_3.NH_3)R(NH_3R)$.
" 5. *Platinitriammines*, $R_2Pt(NH_3.NH_3.NH_3R)_2$.

Series 1 and 3 are isomeric.

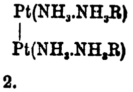
The prefixes *mono*, *di*, &c., are used to denote the number of NH_3 groups in direct union with one another, and not the number of NH_3 groups in union with the atom of Pt. As the compounds in Series 3 contain one diammine chain, $(NH_3.NH_3)$, they are called *semidiammines*; and as those in Series 4 contain a diammine and a monammine chain, they are called *monodiammines*.

Class III. DIPLATINUM COMPOUNDS.

These contain 2 Pt atoms; the group Pt_2 may be divalent, tetravalent, or hexavalent.

Series 1.

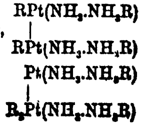
Diplatodiammines,



$$\begin{array}{l}Pt(NH_3.NH_3R)\\ \mid\\ Pt(NH_3.NH_3R)\end{array}$$

Series 2.

Diplatosindiammines,



$$\begin{array}{l}RPt(NH_3.NH_3R)\\ \mid\\ RPt(NH_3.NH_3R)\end{array}\quad\text{or}\quad\begin{array}{l}Pt(NH_3.NH_3R)\\ \mid\\ R_2Pt(NH_3.NH_3R)\end{array}$$

Series 3.

Diplatinammines,
$$\begin{array}{c} RPt(NH_3R)_2 \\ | \\ RPt(NH_3R)_2 \end{array}$$

Series 4.

Diplatinidiammines,
$$\begin{array}{c} RPt(NH_3.NH_3R)_2 \\ | \\ RPt(NH_3.NH_3R)_2 \end{array}$$

Iodides of platinum bases with 4 and 8 atoms Pt are also known; $I_2Pt_4.8NH_3.I_8$, and $I_2Pt_8.16NH_3.I_{16}$.

Many organic bases, such as aniline, pyridene, &c., can take the place of NH_3 in these compounds, and the N of NH_3 is often replaceable by P or As.

Class I. Plato- or Platoso- compounds.

Series 1. *Platosemiammines*, $RPtNH_3R$. None of these has been isolated, but Cossa (*B.* 23, 2503) has obtained a compound which probably contains platosemiammine chloride; the compound is $2PtNH_3Cl_2.Pt(NH_3)_4Cl_2$.

Series 2. *Platosammines*, $Pt(NH_3R)_2$. These compounds are generally obtained by heating the corresponding platodiammines, $Pt(NH_3.NH_3R)_2$, which thus lose $2NH_3$; by heating with NH_3Aq, platodiammines are re-formed; with oxidisers, platini- compounds are obtained.

PLATOSAMMINE CHLORIDE $Pt.NH_3Cl.NH_3Cl$ (Peyrone, *A.* 51, 1; 55, 205; 61, 178). Obtained by heating $Pt(NH_3)_4Cl_2$ (plato-diammine chloride) to 250°, or by evaporating that compound with HClAq at 100° and dissolving out AmCl in water; also by evaporating with HCl the solution of the corresponding nitrate or sulphate. Microscopic, sulphur-yellow crystals. S. ·022 at 0°, ·77 at 100°. Sol. NH_3Aq, forming $Pt(NH_3.NH_3Cl)_2$ (platodiammine chloride); in *aqua regia* forms $Cl_2Pt(NH_3Cl)_2$ (platinammine chloride). With $AgNO_3Aq$, in the ratio $2Pt(NH_3Cl)_2:AgNO_3$, one half of the chloride remains unchanged and one half gives $Pt(NH_3.NO_3)_2$. Heated to 270°, the chloride is decomposed thus:

$$3Pt(NH_3Cl)_2 = 3Pt + 4NH_4Cl + 2HCl + N_2.$$

Platosemidiammine chloride $Pt(NH_3.NH_3Cl)Cl$, and *platodiammine chloride platinous chloride* $Pt(NH_3.NH_3Cl)_2.PtCl_2$ (Magnus' green salt), are isomeric or polymeric with platosammine chloride. Other compounds, perhaps also isomeric, were obtained by Peyrone (*l.c.*) and by Cossa (*B.* 23, 2503).

Grimm (*A.* 99, 67) obtained a double compound with AmCl; $Pt(NH_3Cl)_2.2AmCl$. Jörgensen (*J. pr.* [2] 33, 489) obtained the pyridine compound $Pt(NC_5H_5Cl)_2$; and also the mixed compound $PtNC_5H_5Cl.NH_3Cl$ (*v.* also Hedin, *Dissertation*, Lund; *B.* 20, *Ref.* 108).

PLATOSAMMINE HYDROXIDE $Pt.NH_3OH.NH_3OH$. Said to be obtained, as a crystalline, very soluble solid, by decomposing the sulphate, $Pt(NH_3.NH_3)SO_4$, by BaOAq (Odling, *C. N.* 21, 269, 289). The compound thus formed may have been the isomeric *platosemidiammine hydroxide*, $OH.Pt(NH_3.NH_3OH)$. A solution of Odling's hydroxide reacts strongly alkaline, absorbs CO_2 from the air, neutralises acids, decomposes salts of NH_4 giving off NH_3, and ppts. many metallic hydroxides from salts of the metals.

PLATOSAMMINE OXIDE $Pt(NH_3.NH_3)O$. A grey solid, insol. water or NH_3Aq; heated in a retort to 195° gives N, NH_3, H_2O and Pt. Obtained by heating platodiammine hydroxide $(Pt[NH_3.NH_3.OH]_2)$ to 110° (Reiset, *A. Ch.* [3] 11, 417).

PLATOSAMMINE SULPHONATES and CHLOROSULPHONATES $Pt.NH_3SO_3M.NH_3SO_3M$ and $Pt.NH_3Cl.NH_3SO_3M$. *Ammonium platosammine sulphonate*, $Pt(NH_3.SO_3Am)_2$, is formed by the reaction of excess of Am_2SO_3Aq on $Pt(NH_3Cl)_2$ (Peyrone, *A.* 51, 1; 55, 205; 61, 178). The salts of Ba, Co, Cu, Pb, Mn, Ni, Ag, Na, UO_2, and Zn have been obtained. *Ammonium platosammine chlorosulphonate*, $Pt.NH_3Cl.NH_3SO_3Am.H_2O$, is obtained, in colourless rhombic tablets, by leading SO_2 into a boiling solution of $Pt(NH_3Cl)_2$, and neutralising with NH_3Aq. If the neutralisation is omitted, *platosammine chlorosulphonic acid*, $Pt.NH_3Cl.NH_3.SO_3H$, is obtained (Peyrone, *l.c.*).

The other salts of the platosammine series which have been isolated are the following; $M = Pt(NH_3)_2$:—*bromide*, MBr_2 (Jörgensen, *J. pr.* [2] 33, 521, 531, 535); *cyanide*, MCy_2 (Buckton, *A.* 92, 280); *iodide*, MI_2 (Cleve, *Bl.* [2] 7, 12; 17, 482; Reiset, *A. Ch.* [3] 11, 417); *nitrate* and *nitrite*, $M(NO_3)_2$ and $M(NO_2)_2$ (Cleve, *l.c.*); *sulphate* and *sulphite*, $MSO_4.H_2O$ and $MSO_3.H_2O$ (Cleve, *l.c.*); and *sulphocyanide*, $M(CyS)_2$ (Buckton, *l.c.*). Substituted derivatives of the bromide, of the form $Pt(NH_2RBr)_2$ and $Pt.NH_3Br.NH_2RBr$, where R = Et, Me, or Pr, have been obtained (Jörgensen, *l.c.*).

Series 3.—*Platodiammines* $Pt(NH_3.NH_3R)_2$. Formed by action of NH_3Aq on platinous salts, platosammine or platosemidiammine compounds. Easily lose NH_3 on heating, giving platosammine compounds. Give platinidiammine compounds by action of oxidisers.

PLATODIAMMINE CHLORIDE $Pt(NH_3.NH_3Cl)_2.H_2O$ (Reiset, *A. Ch.* [3] 11, 417). Sometimes called *Reiset's first chloride.* Obtained by the prolonged action of boiling NH_3Aq on $PtCl_2$, Magnus's green salt (*v. infra*), platosammine chloride $Pt(NH_3Cl)_2$, or platosemidiammine chloride $Pt(NH_3.NH_3Cl)Cl$, precipitation by alcohol, and crystallisation from water. Also formed by reduction of platinidiammine chloride $Cl_2Pt(NH_3.NH_3Cl)_2$, by H_2S (Thomsen, *J.* 1868. 278). Large, colourless, tetragonal crystals; S. 25 at 16·5°, more sol. hot water; insol. absolute alcohol and ether. Addition of H_2SO_4Aq, HNO_3Aq, or $H_2C_2O_4Aq$ ppts. the corresponding sulphate, nitrate, or oxalate. By gently warming with HNO_3Aq the salt $(NO_3)_2Pt(NH_3.NH_3Cl)_2$ is formed; Cl, Br, and $FeCl_3Aq$ react similarly. At 240°–270° NH_3 is given off, and $Pt(NH_3Cl)_2$ is formed (*v.* PLATOSAMMINE CHLORIDE, *supra*). Combines with $PtCl_2$, and $PtCl_4$, to form $M.PtCl_2$ and $M.PtCl_4$ respectively $[M = Pt(NH_3.NH_3Cl)_2]$. Compounds are known in which NH_3 is wholly or partly replaced by pyridine, also by alkyl radicles (Jörgensen, *J. pr.* [2] 33, 489), and also by PEt_3 (Cahours a. Gal, *C. R.* 70, 1381).

Double compounds. Combines with various metallic chlorides to form compounds of the form $M.XCl_2$, where $M = Pt(NH_3.NH_3Cl)_2$, and X = Pt, Cu, Pb, Hg, Sn, and Zn (*v.* Thomsen, *J.* 1868. 278; Buckton, *C. J.* 5, 213; Millon a. Commaille, *C. R.* 57, 822).

The most important of these compounds is PLATODIAMMINE CHLORIDE PLATINOUS CHLORIDE, known as *Magnus's green salt*, $\mathrm{Pt(NH_3.NH_3Cl)_2.PtCl_2}$. This salt is obtained by the action of $\mathrm{NH_3Aq}$ on $\mathrm{PtCl_2}$ in HClAq, or on $\mathrm{PtCl_4}$ in HClAq after passing in $\mathrm{SO_2}$ till AmCl ceases to give a pp. (Magnus, *P.* 14, 242; Gros, *A.* 27, 241). Also by adding $\mathrm{Pt(NH_3.NH_3Cl)_2}$ to $\mathrm{PtCl_2}$ in HClAq. It is best prepared by making $\mathrm{Am_2PtCl_4}$, from $\mathrm{PtCl_4}$ in HClAq treated with $\mathrm{SO_2}$ and crystallised from AmClAq, and heating this with HClAq and $\mathrm{NH_3Aq}$ (Claus, *A.* 107, 138). Green, microscopic prisms or needles; insol. water, alcohol, and dilute HClAq. Digestion with hot $\mathrm{NH_3Aq}$ forms $\mathrm{Pt(NH_3.NH_3Cl)_2}$; Cl, Br, or $\mathrm{HNO_3Aq}$ produces platinidiammines (Gros, *l.c.*; Raewsky, *A. Ch.* [3] 22, 278). Boiling with $\mathrm{AgNO_3Aq}$ produces $\mathrm{PtCl_2}$ and $\mathrm{Pt(NH_3.NH_3NO_3)_2}$. If the empirical formula $n\mathrm{Pt(NH_3)_2Cl_2}$ is given to Magnus's green salt, it is seen to be isomeric, or polymeric, with platosammine chloride $\mathrm{Pt(NH_3Cl)_2}$, platosemidiammine chloride $\mathrm{Cl_2Pt.NH_3.NH_3Cl}$, platomonodiammine chloride platinous chloride $\mathrm{2[Pt(NH_3.Cl)(NH_3.NH_3Cl)].PtCl_2}$, diplatosindiammine chloride $\mathrm{Cl_2Pt_2(NH_3.NH_3Cl)_2}$, and with a double salt obtained by Cossa (*B.* 23, 2503), $\mathrm{2[Pt.NH_3.Cl_2].Pt(NH_3)_4Cl_2}$.

PLATODIAMMINE HYDROXIDE $\mathrm{Pt(NH_3.NH_3OH)_2}$. Sometimes called *Reiset's first base* (Reiset, *A. Ch.* [3] 11, 417). White, crystalline, deliquescent needles; by decomposing the sulphate by the proper quantity of BaOAq, filtering, and evaporating *in vacuo*. Solution in water is strongly alkaline, absorbs $\mathrm{CO_2}$ from the air, and drives out $\mathrm{NH_3}$ from $\mathrm{NH_4}$ salts. $\mathrm{NH_3}$ is not given off when an aqueous solution is boiled alone or with potash. Melts at c. 110°; at a higher temperature gives off $\mathrm{NH_3}$ and $\mathrm{H_2O}$ and leaves platosammine oxide $\mathrm{Pt(NH_3)_2O}$ (*q. v.* p. 293).

The other chief compounds of the platodiammine series are the following; $\mathrm{M = Pt(NH_3)_4}$:— *carbonates*, $\mathrm{MCO_3.4aq}$ and $\mathrm{M(CO_3H)_2}$ (Peyrone, *A.* 51, 14; Reiset, *A. Ch.* [3] 11, 417); *chromates* $\mathrm{MCrO_4}$ and $\mathrm{MCr_2O_7}$; *bromide*, $\mathrm{MBr_2.3aq}$ (Cleve, *J.* 1867. 321); *iodide*, $\mathrm{MI_2}.x\mathrm{aq}$ (Cleve); *nitrate* and *nitrite*, $\mathrm{M(NO_3)_2}$ and $\mathrm{M(NO_2)_2.2aq}$ (Peyrone, *l.c.*); *phosphate*, $\mathrm{MHPO_4.aq}$ (Cleve, *Bl.* [2] 7, 12; 17, 482); *sulphate* and *sulphites*, $\mathrm{MSO_4}$, $\mathrm{MSO_3}$, $\mathrm{M(SO_3H)_2.2aq}$ (Cleve, *l.c.*).

Series 4. *Platosemidiammines*, $\mathrm{Pt(NH_3.NH_3R)R}$. Generally formed from the chloride by double decomposition; the chloride is a product of the action of $\mathrm{NH_3Aq}$ or $\mathrm{(NH_4)_2CO_3Aq}$ on $\mathrm{PtCl_2}$. Prolonged treatment of the platosemidiammines with $\mathrm{NH_3Aq}$ produces diammine compounds. Jörgensen (*J. pr.* [2] 33, 489) has replaced $\mathrm{NH_3}$ in these compounds by alkyl radicles and by pyridine.

PLATOSEMIDIAMMINE CHLORIDE $\mathrm{Pt}<\begin{matrix}\mathrm{NH_3.NH_3Cl}\\ \mathrm{Cl}\end{matrix}$. Sometimes called *Peyrone's chloride*. $\mathrm{PtCl_2}$ is formed by the action of $\mathrm{SO_2}$ on $\mathrm{PtCl_4}$ in HClAq, and the solution is heated to boiling with excess of $\mathrm{(NH_4)_2CO_3}$ until the red solution has become light-yellow and a greenish-brown pp. forms, when the liquid is rapidly filtered. The chloride separates as the liquid cools; it must be filtered off at once (else it may re-dissolve), and crystallised from boiling water (Peyrone, *A.* 51, 14; 55, 209; *v.* also Thomsen, *Gm.-K.* 8, 1115; Cleve, *Bl.* [2] 7, 12, 17, 482). Small yellow crystals. S. ·26 at 0°, 3·6 at 100°. Decomposes at 270°, giving off $\mathrm{NH_3}$ and HCl. Boiling $\mathrm{NH_3Aq}$ forms platodiammine chloride, $\mathrm{Pt(NH_3.NH_3Cl)_2}$; Cl, Br, I, and some other oxidisers produce platinisemidiammine compounds, $\mathrm{R_2Pt(NH_3.NH_3R)R}$. With $\mathrm{AgNO_3}$, and $\mathrm{Ag_2SO_4}$, the corresponding nitrate and sulphate are formed.

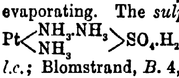
It is doubtful whether the *hydroxide* $\mathrm{Pt(NH_3.NH_3OH)OH}$ has been prepared; the compound obtained by Odling (*C. N.* 21, 269, 289) was this or the isomeric platosammine hydroxide, $\mathrm{Pt(NH_3OH)_2}$ (*v.* PLATOSAMMINE HYDROXIDE, p. 293). The other compounds of this series which have been obtained are the following; $\mathrm{M = Pt.NH_3.NH_3}$:—*bromide*. $\mathrm{MBr_2}$; *chloro-sulphonic acid*, $\mathrm{MCl.SO_3H}$ (Cleve. *l.c.*); *iodide*, $\mathrm{MI_2}$; *nitrate* and *nitrite*, $\mathrm{M(NO_3)_2}$ and $\mathrm{M(NO_2)_2}$; *sulphate*, $\mathrm{MSO_4}$; *double sulphites*, $\mathrm{MSO_3.2X_2SO_3}$, $\mathrm{X_2 = 2NH_4}$, Ba. Co, $\mathrm{Ag_2}$; these may be regarded as compounds of sulphites with salts of the *hypothetical platosemiammine sulphonic acid* $\mathrm{Pt(NH_3.NH_3.SO_3H)SO_3H}$.

Series 5. *Platomonodiammines* $\mathrm{Pt(NH_3.NH_3R)(NH_3R)}$. Most of the salts of this series are prepared from the double salt of the chloride with $\mathrm{PtCl_2}$.

PLATOMONODIAMMINE CHLORIDE PLATINOUS CHLORIDE $\mathrm{2Pt}<\begin{matrix}\mathrm{NH_3.NH_3Cl}\\ \mathrm{NH_3Cl}\end{matrix}\mathrm{.PtCl_2}$. This compound is one product of the action of $\mathrm{NH_3Aq}$ on $\mathrm{PtCl_2}$ in HClAq; it is prepared by neutralising $\mathrm{PtCl_2}$ in HClAq by $\mathrm{(NH_4)_2CO_3Aq}$, heating to boiling, and adding $\mathrm{(NH_4)_2CO_3Aq}$ drop by drop, when it separates in small red tablets (Peyrone, *A.* 55, 209). Fairly sol. cold water, more sol. hot water. Boiled with $\mathrm{NH_3Aq}$ forms Magnus's green salt, $\mathrm{Pt(NH_3.NH_3Cl)_2.PtCl_2}$. Isomeric, or polymeric, with Magnus's green salt, platosammine chloride, and platosemidiammine chloride.

PLATOMONODIAMMINE CHLORIDE $\mathrm{Pt}<\begin{matrix}\mathrm{NH_3.NH_3Cl}\\ \mathrm{NH_3Cl}\end{matrix}$. Obtained, in lustrous colourless crystals, by adding HClAq to an ice-cold solution of the nitrate.

PLATOMONODIAMMINE NITRATE $\mathrm{Pt}<\begin{matrix}\mathrm{NH_3.NH_3NO_3}\\ \mathrm{NH_3NO_3}\end{matrix}$. Formed by decomposing the chloride in solution by $\mathrm{AgNO_3Aq}$, filtering, and evaporating. The *sulphate*



$\mathrm{Pt}<\begin{matrix}\mathrm{NH_3.NH_3}\\ \mathrm{NH_3}\end{matrix}>\mathrm{SO_4.H_2O}$ is also known (*v.* Cleve, *l.c.*; Blomstrand, *B.* 4, 40, 639, 673; 6, 1469).

Class II. Platini- or Platin- compounds.

Series 1. *Platinammines*, $\mathrm{R_2Pt(NH_3R)_2}$. These compounds are formed by the addition of Cl, Br, or I to platosammines, or by the action of such oxidisers as $\mathrm{HNO_3Aq}$ on platosammines; they are generally changed to platinidiammines by heating with $\mathrm{NH_3Aq}$, and are reduced to platosammines by $\mathrm{SO_2Aq}$. The radicles in direct union with Pt are replaced with more difficulty than those in union with $\mathrm{NH_3}$. The nomenclature is arranged to indicate, first, the nature of the radicles in direct union with Pt, and then those in direct union with $\mathrm{NH_3}$.

I. *Chloro- compounds* $\mathrm{Cl_2Pt(NH_3R)_2}$.

CHLOROPLATINAMMINE CHLORIDE $\mathrm{Cl_2Pt(NH_3Cl)_2}$. Formed by suspending platosammine chloride,

$Pt(NH_3Cl)_2$ in boiling water, and passing in Cl until the original citron-yellow particles are changed to microscopic yellow octahedra (Gerhardt a. Laurent, *C. R.* 30, 273), or until the liquid, which is yellow at first, begins to turn reddish. *Aqua regia*, or $KMnO_4Aq$ and HClAq, may be used instead of Cl (Odling, *C. N.* 21, 269, 289). A heavy, yellow, crystalline powder. S. 1 at 0°; 3 at 100°. Unacted on by boiling conc. HNO_3 or H_2SO_4; sol. boiling KOHAq without evolution of NH_3; sol. NH_3Aq, with formation of chloroplatinidiammine chloride, $Cl_2Pt(NH_3.NH_3Cl)_2$. The Cl is ppd. as AgCl only after long boiling with $AgNO_3Aq$ (Grimm, *A.* 99, 67).

CHLOROPLATINAMMINE NITRITE

$Cl_2Pt(NH_3.NO_2)_2$. Ppd. in colourless rhombic plates by addition of excess of HClAq to solution of the nitrato-nitrite, $(NO_3)_2Pt(NH_3.NO_2)_2$, which is formed by boiling platosammine nitrite, $Pt(NH_3.NO_2)_2$, with HNO_3Aq.

CHLOROPLATINAMMINE CHLORONITRITE

$Cl_2Pt(NH_3Cl)(NH_3.NO_2)$, is produced by the reaction of K_2PtCl_4 and $(NO_3)_2Pt(NH_3NO_2)_2$.

II. *Hydroxyl compounds*

$(OH)_2Pt(NH_3R)_2$.

HYDROXYL PLATINAMMINE HYDROXIDE

$(OH)_2Pt(NH_3.OH)_2$. Yellow, lustrous crystals; by adding excess of NH_3Aq to a boiling solution of the nitrato-nitrate $(NO_3)_2Pt(NH_3.NO_3)_2$, and allowing to cool. Scarcely sol. water; easily sol. dilute acids. Boiling KOHAq does not evolve NH_3; decomposes above 130°, giving off NH_3 and H_2O, and leaving Pt (Gerhardt a. Laurent, *C. R.* 30, 273).

HYDROXYL PLATINAMMINE NITRATE

$(OH)_2Pt(NH_3.NO_3)_2.2aq$. Crystalline pp. by decomposing $Cl_2Pt(NH_3Cl)_2$ by $AgNO_3Aq$. Not acted on by cold HClAq; evaporation with HNO_3Aq produces $(NO_3)_2Pt(NH_3.NO_3)_2$ (G. a. L., *l.c.*; Cleve, *Bl.* [2] 7, 12; 17, 482).

HYDROXYL PLATINAMMINE SULPHATE

$(OH)_2Pt(NH_3)_2SO_4.aq$. Formed as a pale-yellow, hard crust of needle-shaped crystals, by decomposing $Cl_2Pt(NH_3.Cl)_2$ by Ag_2SO_4Aq. Evaporation with H_2SO_4Aq produces the sulphato-sulphate, $SO_4.Pt.(NH_3)_2SO_4.3aq$; when HClAq is used, $Cl_2Pt(NH_3)_2SO_4$ and $Cl_2Pt(NH_3Cl)_2$ are produced (Cleve, *l.c.*).

The following salts of this series have also been isolated: *Bromo-bromide*, $Br_2Pt(NH_3Br)_2$ (Cleve, *l.c.*); *bromo-nitrite*, $Br_2Pt(NH_3.NO_2)_2$ (Cleve, *l.c.*); *iodo-iodide*, $I_2Pt(NH_3I)_2$ (Cleve, *l.c.*); *nitrato-nitrate*, $(NO_3)_2Pt(NH_3.NO_3)_2$; *nitrato-nitrite*, $(NO_3)_2Pt(NH_3.NO_2)_2$; *nitrato-chloro-nitrite*, $NO_3.Cl.Pt(NH_3NO_2)_2$ (Cleve, *l.c.*); *sulphato-sulphate*, $SO_4.Pt(NH_3)_2SO_4.3aq$ (Cleve, *l.c.*).

Series 2. *Platinidiammines*,

$R_2Pt(NH_3NH_3R)_2$. Generally formed by action of Cl, Br, I, and other oxidisers on platodiammines. A large number of these compounds is known. R attached directly to Pt may be the same as, or different from, R united directly to NH_3. The nomenclature is similar to that of the platinammine series. The radicles in direct union with Pt are removed with more difficulty than those united with NH_3.

I. *Chloro-compounds*

$ClR.Pt(NH_3.NH_3R)(NH_3.NH_3R)$; the R's may be the same or different.

CHLOROPLATINIDIAMMINE CHLORIDE

$Cl_2Pt(NH_3.NH_3Cl)_2$. By passing Cl into a fairly conc. boiling solution of platodiammine chloride, $Pt(NH_3.NH_3Cl)_2$, till the liquid begins to turn red (Raewsky, *A. Ch.* [3] 22, 278); also by dissolving chloroplatinammine chloride, $Cl_2Pt(NH_3Cl)_2$, in NH_3Aq (Gerhardt a. Laurent, *C. R.* 30, 273). Pale-yellow, crystalline powder; scarcely sol. cold water, sl. sol. boiling water. HNO_3Aq produces the *chloro-nitrate* $Cl_2Pt(NH_3.NH_3.NO_3)_2$; a little $AgNO_3Aq$ produces the *chloro-hydroxyl-nitrate* $Cl(OH)Pt(NH_3.NH_3.NO_3)_2$; long boiling with $AgNO_3Aq$ is needed to remove all Cl as AgCl. Reduced by H_2S, or action of Ag, to $Pt(NH_3.NH_3Cl)_2$ (Thomsen, *J.* 1868. 278; Jörgensen, *J. pr.* [2] 33, 489). Forms double compounds with $PtCl_2$ and $PtCl_4$ (Reiset, *A. Ch.* [3] 11, 417; G. a. L., *l.c.*; Cleve, *Bl.* [2] 7, 12; 17, 482).

The other chloro- compounds which are known are the following: *Chloro-nitrate*, $Cl_2Pt(NH_3.NH_3.NO_3)_2$ (Gros, *A. Ch.* [2] 69, 204; Raewsky, *A. Ch.* [3] 22, 278; Hadow, *C. J.* [2] 4, 345); *chloro-chloro-nitrite*, $Cl_2Pt(NH_3.NH_3.NO_2)(NH_3.NH_3Cl)$; *chloro-hydroxyl-chloride*, $Cl(OH)Pt(NH_3.NH_3Cl)_2$ (Cleve, *l.c.*; Hadow, *l.c.*); *chloro-hydroxyl-carbonate*, $Cl(OH)Pt(NH_3.NH_3)_2CO_3.H_2O$ (Raewsky, *l.c.*; Gros, *l.c.*); *chloro-hydroxyl-chromate* and *dichromate*, $Cl(OH)Pt(NH_3.NH_3)_2CrO_4$ and $Cl(OH)Pt(NH_3.NH_3)_2Cr_2O_7$ (Cleve, *l.c.*); *chloro-hydroxyl-nitrate*, $Cl(OH)Pt(NH_3.NH_3.NO_3)_2$, (Raewsky, *l.c.*; G. a. L., *l.c.*; Cleve, *l.c.*); *chloro-chromate* and *dichromate*, and *chloro-sulphate*, $MCrO_4$, MCr_2O_7, and MSO_4, where $M = Cl_2Pt(NH_3.NH_3)_2$ (Cleve, *l.c.*).

II. *Bromo-compounds.* The following members of this class have been isolated (Cleve, *l.c.*); *bromo-bromide*, MBr_2; *bromo-chloride*, MCl_2; *bromo-dichromate*, MCr_2O_7; *bromo-nitrate*, $M(NO_3)_2$; *bromo-phosphate*, $M(PO_4H_2)_2.2aq$ (in these formulæ $M = Br_2Pt(NH_3.NH_3)_2$); *bromo-chloro-chloride*, $BrClPt(NH_3.NH_3Cl)_2$; *bromo-hydroxyl-chloride* and *nitrate*, MCl_2 and $M(NO_3)_2$, where $M = Br(OH)Pt(NH_3.NH_3)_2$.

III. *Hydroxyl compounds. Hydroxyl-nitrate* and *sulphate*, $M(NO_3)_2$ and MSO_4, where $M = (OH)_2Pt(NH_3.NH_3)_2$.

IV. *Iodo-compounds. Iodo-iodide*, MI_2; *iodo-nitrate*, $M(NO_3)_2$; *iodo-sulphate*, MSO_4; where $M = I_2Pt(NH_3.NH_3)_2$.

IV. *Carbonato-compounds. Carbonato-bromo-carbonate*, *carbonato-chloro-carbonate*, and *carbonato-nitrato-carbonate*, $Br_2(CO_3)R$, $Cl_2(CO_3)R$, and $(NO_3)_2CO_3R$, where

$$R = 2[Pt(NH_3.NH_3)_2].(CO_3)_2.$$

V. *Nitrato-compounds* (Cleve, *l.c.*; Gerhardt a. Laurent, *C. R.* 30, 273):

$(NO_3)_2Pt(NH_3.NH_3Cl)_2.2aq$;

$(NO_3)_2Pt(NH_3.NH_3NO_3)_2$;

$(NO_3)_2Pt(NH_3.NH_3)_2CrO_4$;

$(NO_3)_2Pt(NH_3.NH_3)_2Cr_2O_7$;

$OH(NO_3)Pt(NH_3.NH_3.NO_3)_2$;

$Cl(NO_3)Pt(NH_3.NH_3)_2SO_4.aq$;

$Cl(NO_3)Pt(NH_3.NH_3.NO_3)_2$.

VI. *Nitrito-compounds* (Cleve, *l.c.*; Hadow, *C. J.* [2] 4, 345):

$(NO_2)_2Pt(NH_3.NH_3.NO_3)_2$;

$I(NO_2)Pt(NH_3.NH_3.NO_3)_2$.

VII. ***Sulphato- compounds*** (Cleve, *l.c.*): $(SO_4)Pt(NH_3.NH_3)_2SO_4.aq$;

$$\begin{array}{c} OH.Pt(NH_3.NH_3)_2Cl.2aq; \\ \diagdown SO_4 \diagup \end{array}$$

$OH(SO_4)Pt(NH_3.NH_3)_2SO_4.3aq$; $Br_2(SO_4)Pt(NH_3.NH_3)_4(SO_4)_2.aq$.

Series 3. *Platinisemidiammines*, $R_2Pt(NH_3.NH_3R)R$. These compounds are isomeric with the platinammines, $R_2Pt(NH_3R)_2$. They are generally formed by oxidising the platosemidiammines, $Pt(NH_3.NH_2R)R$.

CHLOROPLATINISEMIDIAMMINE CHLORIDE $Cl_2Pt(NH_3.NH_3Cl)Cl$. By chlorinating platosemidiammine chloride, $Pt(NH_3.NH_3Cl)Cl$, by Cl or *aqua regia* (Cleve, *l.c.*). Orange, crystalline powder; S. ·33 at 0°, 1·52 at 100°. Not acted on by conc. H_2SO_4 or alkali solutions.

The following salts of this series are known (Cleve, *l.c.*):
bromo-bromide, $Br_2Pt(NH_3.NH_3Br)Br$;
bromo-nitrite, $Br_2Pt(NH_3.NH_3.NO_2)NO_2$;
chloro-nitrite, $Cl_2Pt(NH_3.NH_3.NO_2)NO_2$;
chloro-hydroxyl-nitro-nitrite, $Cl(OH)Pt(NH_3.NH_3.NO_2)NO_2$;
trihydroxyl-nitrate, $(OH)_2Pt(NH_3.NH_3.NO_3)OH$;
hydroxyl-sulphate, $\begin{array}{c} (OH)_2PtNH_3.NH_3 \\ \diagdown SO_4 \diagup \end{array}$.

Series 4. *Platinimonodiammines*, $R_2Pt(NH_3.NH_3R)(NH_3R)$. Of this series the following have been isolated (Cleve, *l.c.*): *bromo-nitrate*, $Br_2Pt(NH_3.NH_3.NO_3)(NH_3.NO_3)$; *bromo-sulphate*, $Br_2Pt(NH_3.NH_3.SO_4.NH_3).aq$; *chloro-chloride*, $Cl_2Pt(NH_3.NH_3Cl)(NH_3Cl)$; *hydroxyl-nitrate*, $(OH)_2Pt(NH_3.NH_3.NO_3)(NH_3.NO_3).aq$; *hydroxyl-bromo-nitrate*, $(OH)BrPt(NH_3.NH_3.NO_3)(NH_3.NO_3).aq$; *iodo-bromide*, $I_2Pt(NH_3.NH_3Br)(NH_3Br)$.

Series 5. *Platinitriammines*, $R_2Pt(NH_3.NH_3.NH_3R)_2$. This constitution is probably to be given to salts formed by electrolysing ammonium carbamate or carbonate solution, using electrodes of Pt (Drechsel, *J. pr.* [2] 20, 378; 26, 277; Gerdes, *J. pr.* [2] 26, 257). The salt formed as described is probably ***carbonato-platinitriammine carbonate***, $(CO_3).Pt\begin{array}{c}\diagup NH_3.NH_3.NH_3 \diagdown \\ \diagdown NH_3.NH_3.NH_3 \diagup\end{array}CO_3$. By the action of HNO_3, H_2SO_4, and HCl, respectively, on this compound are obtained the *nitrato-nitrate*, *sulphato-sulphate*, and *chloro-chloride*, $(NO_3)_2.M.(NO_3)_2$, $SO_4.M.SO_4.aq$, and $Cl_2.M.Cl_2$, where $M = Pt(NH_3.NH_3.NH_3)_2$.

Class III. Diplatinum compounds.

Series 1. *Diplatodiammines*, $\begin{array}{l} Pt(NH_3.NH_3R) \\ | \\ Pt(NH_3.NH_3R) \end{array}$ (Blomstrand, *J. pr.* [2] 3, 207). Cleve (*l.c.*) gives to these compounds the formula

$$Pt_2(NH_3)_2(NH_2)_2R_2.$$

The following members of this series are known: *chloride*, MCl_2; *hydroxide*, $M(OH)_2$; *nitrate*, $M(NO_3)_2$; and *sulphate*, MSO_4; where $M = Pt_2(NH_3)_4$.

Series 2. *Diplatosindiammines*, $\begin{array}{l} RPt(NH_3.NH_3R) \\ | \\ RPt(NH_3.NH_3R) \end{array}$. The only compound of this series is the *chloride* $Cl_2Pt_2(NH_3)_4Cl_2$.

Series 3. *Diplatinammines*, $\begin{array}{l} RPt(NH_3R)_2 \\ | \\ RPt(NH_3R)_2 \end{array}$. The only compound of this series is the *iodide* $I_2Pt_2(NH_3)_4I_4$ (Cleve, *l.c.*); by treatment with HIAq, the compound $Pt_4I_{10}(NH_3)_8$ and $Pt_8I_{13}(NH_3)_{16}$ are produced.

Series 4. *Diplatinidiammines*, $\begin{array}{l} RPt(NH_3.NH_3R)_2 \\ | \\ RPt(NH_3.NH_3R)_2 \end{array}$ (Cleve, *l.c.*). The iodo-nitrate, $I_2Pt_2(NH_3)_8(NO_3)_4$, is formed by reacting on $I_2Pt(NH_3)_4(NO_3)_2$ with NH_3Aq and treating the product with HNO_3Aq; most of the other compounds of the series are formed from the iodo-nitrate. Various classes of compounds of this series are formed by varying the composition of the radicles, R; the nomenclature is similar to that used for the platinidiammines. The compounds which have been isolated are *bromo-nitrate*, *bromo-anhydronitrate*, and *bromosulphate*, $M(NO_3)_4$, $M(NO_3)_2O$, and $M(SO_4)_2.2aq$, where $M = Br_2Pt_2(NH_3)_8$; *hydroxyl-chloride*, *dichromate*, *phosphate*, and *sulphate*, $MCl_4.aq$, $M(Cr_2O_7)_2$, $M(HPO_4)_2$, and $M(SO_4)_2.2aq$, where $M = (OH)_2Pt_2(NH_3)_8$; *iodo-iodide*, *anhydro-iodide*, *nitrate*, *anhydronitrate*, *phosphate*, and *sulphate*, MI_4, MI_2O, $M(NO_3)_4.4aq$, $M(NO_3)_2O$, $M(HPO_4)_2$, and $M(SO_4)_2$, where $M = I_2Pt_2(NH_3)_8$; *nitrato-nitrate*, $(NO_3)_2Pt_2(NH_3)_8(NO_3)_4.4aq$.

M. M. P. M.

PLATINUMS, FULMINATING. Various compounds of Pt, N, Cl, O, and H, all of which explode when heated, are formed by the action of KOHAq on $(NH_4)_2PtCl_6$, or by ppg. $Pt(SO_4)_2$ with NH_3Aq and boiling the pp. with KOHAq (Proust, *Gehlen's J.* 1, 348; Döbereiner, *G. A.* 72, 194; Fourcroy a. Vauquelin, *Gehlen's J.* 1, 348; Davy, *S.* 19, 91). These compounds are classed together as *fulminating platinums*. E. von Meyer (*J. pr.* [2] 18, 305) classifies according to the quantities of Cl they contain; all contain Pt and N in the ratio of equal numbers of atoms: *tetrachloro- compound* $Pt_4N_4Cl_4O_{12}H_{24}$, *trichloroxy-* $Pt_4N_4Cl_3(OH)O_{12}H_{24}$, *dichloro-* $Pt_4N_4Cl_2O_{12}H_{22}$, *chloroxy-* $Pt_4N_4Cl(OH)O_{12}H_{22}$. Tetrachloro-fulminating platinum is formed by adding KOHAq drop by drop to Am_2PtCl_6, in the ratio 4·6KOH : Am_2PtCl_6, and washing the pp. by repeatedly boiling with acetic acid solution and then with water. At 150° $4H_2O$ is given off; explosion occurs at a higher temperature. Dilute H_2SO_4Aq produces $H_2C_2O_4$ and evolves CO_2. By treatment with KOHAq, or NH_3Aq, Cl_2 is easily removed, a third Cl is removed with difficulty, but the fourth Cl remains unattacked.

M. M. P. M.

PLUMBAGO. A name sometimes given to graphite; *v.* CARBON, vol. i. p. 686.

PLUMBATES. Salts wherein PbO_2 acts as acidic radicle, *v.* vol. iii. p. 132.

PLUMBITES. Salts wherein PbO acts as acidic radicle, *v.* vol. iii. p. 129.

PLUMERIC ACID $C_{10}H_{10}O_5$. [139°]. Occurs as calcium salt in the milky juice of *Plumeria acutifolia* (Oudemans, *A.* 181, 154). Minute crystals (from water), v. sol. alcohol and ether, sl. sol. cold water. Yields salicylic acid on fusion with KOH. Reduced by sodium-amalgam to crystalline 'hydroplumeric' acid $C_{10}H_{12}O_5$.—K_4A^{iv} 8aq. — $Ca(H_3A^{iv})_2$ 4aq. S. ·5 at 20°. — CaH_2A^{iv} 5aq. S. ·25 at 20°.—$Ca_3(HA^{iv})_2$ 8aq.— $Ag_2H_2A^{iv}$ aq. — Ag_3HA^{iv} $1\frac{1}{2}$aq: needles (from water).

PODOCARPIC ACID $C_{17}H_{22}O_3$ *i.e.* $C_8H_{15}.C_6H_2Me(OH).CO_2H$. Mol. w. 274. [188°]. $[\alpha]_D = 136°$. Constitutes at least 90 p.c. of the resin found by de Vrij in the trunk of an old tree, *Podocarpus cupressina*, var. *imbricata* (Oudemans, *A.* 170, 213). Plates (from dilute alcohol), insol. water, v. sl. sol. benzene, v. e. sol. alcohol and ether. Dextrorotatory. Resolved at 300° into water and anhydride $C_{34}H_{42}O_5$. Yields methanthrene $C_{15}H_{12}$ on distillation with zinc-dust. The Ca salt on distillation yields *p*-cresol, hydrocarpol, carpene C_9H_{14}, and methanthrol $C_{15}H_{12}O$. Br added to its alcoholic solution forms $C_{17}H_{20}BrEtO_3(EtOH)$ [above 80°], which gives off alcohol when heated for some time, leaving $C_{17}H_{20}BrEtO_3$ [158°].

Salts.—NaA' 7aq. S. 33 at 21°. Needles.—KA' 3aq.—KA' 4aq.—$(NH_4)HA'_2$ aq.—BaA'_2 3aq.—BaA'_2 8aq. — BaA'_2 9aq. — BaA'_2 15aq. — $BaC_{17}H_{20}O_3$ 8aq. — CaA'_2 5aq. — PbA'_2 4aq.—$PbC_{17}H_{20}O_3$ aq. — $PbH_2A'_4$ 10aq. — CuA'_2 10aq.—AgA' $2\frac{1}{2}$aq.

Methyl ether MeA'. [174°]. Grains.

Ethyl ether EtA'. [146°]. Needles.

Acetyl derivative $C_{17}H_{21}AcO_3$. [152°]. Small needles (from dilute alcohol).

Nitropodocarpic acid $C_{17}H_{21}(NO_2)O_3$. [205°]. Formed, as well as the di-nitro- acids, by the action of HNO_3 (S.G. 1·34). Small crystals, insol. water, m. sol. hot alcohol. May be reduced to unstable amido-podocarpic acid, which forms $C_{17}H_{23}NO_3HCl$ $\frac{1}{2}$aq.

Salts.—$(NH_4)_2C_{17}H_{19}NO_5$ 4aq.—$K_2C_{17}H_{19}NO_5$ $5\frac{1}{2}$aq. Red needles with green lustre, v. sol. water.—$Na_2C_{17}H_{19}NO_5$ 9aq. Scarlet plates. — $BaC_{17}H_{19}NO_5$ 7aq. Red needles. — $BaC_{17}H_{19}NO_5$ 3aq.—BaA'_2 4aq: yellow needles, sl. sol. water.—$CaC_{17}H_{19}NO_5$ 4aq: orange needles.

Di-nitro-podocarpic acid $C_{17}H_{20}(NO_2)_2O_3$. [203°]. Pale-yellow crystals, insol. water, m. sol. alcohol.—Salts: $K_2C_{17}H_{18}N_2O_7$ 5aq. Crimson needles, with green reflex.—$BaC_{17}H_{18}N_2O_7$ 4aq.—$Ag_2C_{17}H_{18}N_2O_7$ 4aq: orange pp.

Sulpho-podocarpic acid $C_{17}H_{21}(SO_3H)O_3$ 8aq. Got by warming with H_2SO_4. Amorphous mass. Salts: Na_2A'' 7aq: easily soluble rosettes.—$Ba(HA'')_2$ 6aq. — BaA'' 8aq: white laminæ. — CaA'' 7aq: thin laminæ.

Hydrocarpol $C_{16}H_{20}O$. (220° *in vacuo*). A product of the distillation of calcium podocarpate. Viscid oil, v. sol. alcohol and ether. Yields *p*-cresol, carpene, and methanthrol $C_{15}H_{12}O$ [122°] when distilled. Methanthrol is crystalline, sol. KOHAq.

PODOPHYLLIN. The resin extracted from the root of *Podophyllum peltatum* (Guareschi, *B.* 12, 683; *G.* 10, 16; Busch, *Ph.* [3] 8, 443; Senier a. Lowe, *Ph.* [3] 8, 445). It contains bitter and physiologically active 'picropodophyllin' crystallising in needles [200°-210°], and several resins, *e.g.* 'podophyllo- quercetin' [247°-250°] and 'podophyllic acid' (Podwissotzky, *Ph.* [3] 12, 1011).

POLYCHROÏTE *v.* SAFFRON.

POLYMERISM; a term generally applied to the phenomena of the existence of more than one substance having the same composition, and related in properties, but with different molecular weights; *v.* ISOMERISM, vol. iii. pp. 79-81.

M. M. P. M.

POLYPORIC ACID $C_{18}H_{14}O_4$. [above 300°]. Occurs in a fungus belonging to the genus *Polyporus*, which grows on the bark of diseased or dead oaks. The fungus is yellow, but is turned violet by ammonia (Stahlschmidt, *A.* 187, 177; 195, 365). Bronzed tables (from alcohol), insol. water, ether, benzene, CS_2, and HOAc, sl. sol. chloroform and alcohol. Alkalis form purple solutions, decolourised by zinc-dust. Yields a tetrahydride when boiled with conc. KOHAq. Yields benzene on distillation with zinc-dust. Conc. HNO_3 forms $C_{18}H_{12}(NO_2)_2O_4$ [230°]. $KClO_3$ and HCl give $C_{18}H_{14}Cl_4O_4$ [108°] and $C_{18}H_{12}Cl_4O_2$ [110°].

Salts.—K_2A'' 2aq: purple monoclinic crystals.—Na_2A'' 2aq: violet needles.—$(NH_4)_2A''$ 2aq.—BaA'' 4aq.—BaA'' 2aq.—SrA'' 4aq.—SrA'' aq.—CaA'' 3aq: pale-violet needles. MgA'' 3aq.—Ag_2A'': insoluble pp.

Methyl ether Me_2A''. [187°].

Ethyl ether Et_2A''. [134°]. Needles.

Diacetyl derivative $C_{18}H_{12}Ac_2O_4$. [205°]. Yellow needles, sl. sol. alcohol.

Hydride $C_{18}H_{18}O_4$. [163°]. Formed, together with the acid $C_{20}H_{18}O_2$ [156°] which yields Ag_2A'', by boiling polyporic acid with conc. KOHAq. White crystalline powder (from hot water), sol. alcohol.—Na_2A'' 4aq.—BaA''.—MnA'' 6aq.—Ag_2A'': crystalline pp.

POPPY OIL. The oil expressed from the seeds of *Papaver somniferum* contains glycerides of linoleïc, stearic, and palmitic acids (Oudemans, *J.* 1858. 301; 1863. 333; *cf.* Mulder, *J.* 1865. 323).

POPULIN is the *Benzoyl derivative* of SALICIN.

PORPHYRINE $C_{21}H_{25}N_3O_2$. [97°]. Occurs, together with alstonine and alstonidine, in the bark of *Alstonia constricta* (Hesse, *A.* 205, 366). White amorphous substance, sol. alcohol, ether, and chloroform. Conc. H_2SO_4 gives a purple solution. Its acid solutions exhibit blue fluorescence.—$B'_2H_2PtCl_6$ 4aq.

POTASH. *Potassium hydroxide*, *q. v.*, p. 302.

POTASSIUM. K. At. w. 39·04. Mol. w. probably 39·04 (Ramsay, *C. J.* 55, 521; *v. infra*). M.P. 58° (Quincke, *P.* 135, 642); 62·5° (Bunsen, *A.* 125, 368). B.P. 719°-731° (Carnelley a. Williams, *C. J.* 35, 563); 667° (Perman, *C. J.* 55, 326). S.G. ·865 at 15° (Gay-Lussac a. Thénard); ·875 at 13° (Baumhauer, *B.* 6, 655). V.D. not known with certainty; *v. infra, molecular weight.* S.H. from −78° to +10° ·166 (Regnault, *A. Ch.* [3] 26, 286). C.E. (linear, 0°-50°) ·00008415 (Hagen, *Verhandl. d. physikal. Ges. zu Berlin*, 1882. No. 13). Volume at $t°$ = vol. at 0° $(1 + \cdot00023935t + \cdot0000002\!9925t^2)$ for interval 10° to 95° (Hagen, *l.c.*). E.C. at 0° (Hg at 0° = 1) 11·23; at 100° (liquid) 5·586 (Matthiessen, *P.* 100, 177). Refraction-equiv 7·51 (Kanonnikoff, *J. R.* 1884 (1), 119). The emission-spectrum is characterised by a line K_α in the extreme red, and a line K_β in the violet; for measurements of all the chief lines *v. B. A.* 1884. 436; for the absorption-spectrum *v.* Roscoe a. Schuster, *C. N.* 29, 268. H.C. $[K^2,O] = 66{,}050$ (Woods, *P. M.* [4] 2, 268).

Occurrence.—Compounds of K are widely distributed in large quantities. *Felspar, mica, &c.*, contain silicates of this metal; *carnallite, sylvine, &c.*, contain KCl; *alum-stone* and other minerals contain K_2SO_4; *saltpetre* is chiefly KNO_3. Sea-water contains c. ·5 to ·7 g. KCl per litre. Potassium salts, *e.g.* acid tartrate and oxalate, are found in plants. Animals contain salts of K, chiefly phosphate and chloride.

Historical.—Potash was decomposed by Davy (*T.* 1808. [1] 5) in 1807, by passing the electric current from a Volta-pile of 200 plates, through a piece of potash placed in a Pt basin. Gay-Lussac a. Thénard, in 1808, reduced potash and obtained the metal, by heating it to whiteness with iron filings (*A. Ch.* 65, 325). In the same year Curaudan (*A. Ch.* 66, 97) showed that charcoal could be used instead of iron. Brunner (*S.* 88, 517) made this process applicable on the large scale, and B.'s method was modified by several workers, especially by Donny a. Mareska (*A. Ch.* [3] 35, 147).

Formation.—1. By electrolysing KOH. The most effective method is to place a little conc. KOHAq, with pieces of solid KOH in it, in a Pt basin, to connect this with the negative pole of a powerful battery, to pour a little Hg into the basin, and place therein the wire from the positive pole. The K which is thus formed amalgamates with the Hg; the amalgam, after drying, is heated in a small retort, along with a little mineral oil, which drives out the air, and the K remains when the Hg has been distilled off.—2. By electrolysing a molten mixture of KCl and $CaCl_2$ in the ratio $2KCl:CaCl_2$. Temperature is arranged so that a solid crust remains on the surface of the molten mixture. Electrodes of gas-coke are used. After electrolysis the mixture is allowed to cool for twenty minutes, and the contents of the crucible are scraped out under petroleum (Matthiessen). Linnemann electrolyses molten KCN (*J. pr.* 73, 415).—3. By heating KOH to redness with iron filings or charcoal.—4. By heating an intimate mixture of K_2CO_3 and C, or a mixture of K_2CO_3 or KOH, C, and very finely-divided iron (Castner, *C. N.* 54, 218).—5. By heating sulphide of K with iron filings (Dolbear, *C. N.* 26, 33).—6. By heating potash with sodium under petroleum to c. 170° (Williams, *C. N.* 3, 21).—7. By the action of Na on dry molten K acetate (Wanklyn, *C. N.* 3, 66).

Preparation.—An intimate mixture of K_2CO_3 and C is formed by heating cream of tartar (K-H tartrate) in a closed crucible. The mixture is then strongly heated in an iron bottle, connected with a flat receiver about 30 centim. long, 12 centims. wide, and 6 centims. from the inner surface of one side to that of the other; this receiver is made of two pieces of sheet-iron (about 4 mm. thick) screwed together, and has an opening at the end farthest from the retort, to allow the escape of CO. The reaction may be represented thus: $K_2CO_3 + 2C = 2K + 3CO$. The K distils over and condenses in the receiver; when full the receiver is removed, plunged under mineral oil and there opened, and the K is removed by a chisel. K combines with CO at a red heat to form a black, very explosive substance; the more rapidly the distilled K is cooled the less of this explosive compound is formed. The distilled metal is purified by wrapping it, when under oil, in a piece of linen, heating the oil to c. 65°, and pressing the molten K through the linen; the metal is then redistilled, from an iron bottle, into a copper tube partly filled with mineral naphtha, and having an opening through which an iron rod may be passed to clear the tube which carries the K from the bottle into the receiver (Donny a. Mareska, *A. Ch.* [3] 35, 147). Castner (*C. N.* 54, 218) uses as reducer a mixture of C and a metallic carbide, or a mixture of very finely-divided metal and C (conveniently prepared by heating a mixture of Fe_2O_3 and tar in a covered vessel), and heats in an iron crucible with an exit-tube passing through the lid. The reaction, using KOH, Fe, and C, may be formulated as $3KOH + Fe + 2C = 3K + Fe + CO + CO_2 + 3H$.

Properties.—A silver-white, lustrous metal. As soft as wax at ordinary temperatures, brittle at 0°, melts at c. 60°. Boils when heated in a stream of H to c. 700°, and forms a bright-green vapour. A sublimate, in a very thin film on glass, shows a rich purple colour in transmitted light (Dudley, *C. N.* 66, 163; Newth, *N.* 47, 55). Crystallises in quadratic octahedra, which have a greenish-blue sheen. These crystals are obtained by melting K in a glass tube, narrowed at one place, and filled with coal-gas, and allowing the semi-solidified metal to flow slowly through the constricted part of the tube (Long, *C. J.* 13, 122). Sol. liquid NH_3, forming a blue liquid, from which the metal is obtained by allowing the NH_3 to evaporate (Seeley, *C. N.* 23, 169; *v.* POTASSAMMONIUM, p. 299). Combines very rapidly with O; on exposing a freshly-cut surface to air, oxidation occurs at once. Decomposes cold water rapidly. K must be kept under a liquid free from O, such as mineral naphtha or rock-oil.

The *atomic weight* of K was determined by Berzelius, Penny, Marignac, Pelouze, Millon, Faget, and Maumené, from 1813 to 1846, by reducing $KClO_3$, $KClO_4$, and KIO_3 to KCl and KI, and by converting KCl, KBr, and KI to AgCl, AgBr, and AgI. The researches of Stas, in 1860 and 1865, have determined the at. w. with great accuracy. Stas heated $KClO_3$, thus getting KCl, decomposed $KClO_3$ by HClAq, determined the ratio of KCl and KBr to Ag required for complete ppn., converted KCl into KNO_3 and KBr into AgBr, and determined the ratio of KBr to $AgNO_3$ required for ppn. (Stas, *Rech.* 69, 70, 91, 118; *Nouv. R.* 244, 303).

The *molecular weight* of K is not known with certainty. Dewar a. Dittmar (*C. N.* 27, 121) and Dewar a. Scott (*Pr.* 29, 206, 490) determined the V.D. of K at c. 1000°; the earlier results pointed to a mol. w. of c. 90, and the later numbers to a value c. 45. V. Meyer (*B.* 13, 391) showed that the results were untrustworthy, as vapour of K attacks glass vessels. It has also been shown that vessels of Cu, Ag, Pt, or Fe cannot be used (Rieth, *B.* 4, 807; Meyer, *l.c.*). Ramsay (*C. J.* 55, 521) attempted to find mol. w. of K by dissolving in Hg, and finding the decrease of the vapour-pressure of Hg thereby produced. Assuming the mol. w. of liquid Hg to be 200, and also assuming that equal vols. of dilute solutions contain equal numbers of molecules, the results gave mol. w. of K as 29·1 and 30·2; it seems probable that the mol. of K is monatomic.

The only compound of K whose V.D. has been determined is KI; in this molecule the atom of K is monovalent.

K is a very strongly positive element. In all

its compounds it reacts as a metal, and does not enter into the composition of any negative radicles. K forms very few basic salts, and no oxyhaloid compounds; its halide compounds are very stable towards heat. K is closely related to Cs, Li, Na, and Rb (*v.* ALKALIS, METALS OF THE, vol. i. p. 114).

Reactions.—1. Heated in dry *air* or *oxygen*, K_2O and K_2O_4 are formed (*v. Oxides*, p. 304).—2. At about 300° K absorbs *hydrogen* readily, probably forming K_2H (*v. Hydride*, p. 301).—3. Combines with *chlorine*, *bromine*, and *iodine* when heated (*v. Chlorides, bromides, iodides*, pp. 299, 300, 302).—4. Forms compounds with *sulphur*, *selenion*, and *tellurium* when heated (*v. Sulphides, selenides, tellurides*, pp. 305, 306).—5. Combines with *phosphorus* (*v. Phosphide*, p. 305).—6. Alloys with several *metals* (*v. Alloys*, *infra*).—7. Reacts rapidly with *water*, forming KOHAq and H.—8. Heated with *hydrogen sulphide* forms KHS (*v. Hydrosulphide*, p. 302).—9. Dissolves in *liquid ammonia* (Seeley, *C. N.* 23, 169; *v. infra*, POTASSAMMONIUM). Heated in dry *ammonia gas*, KNH_2 is formed (*v. Amide*, *infra*).—10. Combines with *carbon monoxide* to form KCO (*v. Carbonyl compound*, p. 300). At red heat decomposes CO with separation of C.—11. Decomposes *carbon dioxide*, and *nitrous* and *nitric oxide*, when strongly heated with these compounds.—12. Reacts with *moist carbon dioxide* to form K_2CO_3 and HCO_2K (Kolbe a. Schmitt, *A.* 119, 251).—13. Decomposes *silica* and *boric acid*, when heated with these compounds, probably forming silicide and boride (*q. v.*, pp. 299, 305).

Potassium, alloys of. Alloys of K with most metals are known; K alloys easily with the more fusible metals. The alloys generally oxidise in air, and decompose cold water. K forms amalgams with Hg; according to Joannis (*C. R.* 113, 795), $Hg_{18}K$ is formed by letting potassammonium (*q. v.*) in liquid NH_3 drop on to Hg. For polarisation of K amalgam in KClAq against Zn amalgam *v.* Le Blanc, *Z. P. C.* 5, 467. For supposed alloy with NH_4, *v. infra*, POTASSAMMONIUM.

Potassium, aluminate of; *v.* vol. i. p. 141.

Potassium amide, KNH_2. Gay-Lussac a. Thénard (*G. A.* 29, 135; 32, 23) obtained dark olive-green crystals by heating K in dry NH_3. Baumert a. Landolt (*A.* 111, 1) confirmed G. a. T.'s formula KNH_2. The compound is formed by passing dry NH_3 into a flask of c. 50 c.c. capacity, fitted with a cork carrying an inlet and exit tube, quickly throwing in pieces of K, continuing the passage of NH_3, and heating very gently till the metal just ceases to dissolve in the greenish-blue liquid that is formed; on cooling, a yellowish-brown solid is obtained. KNH_2 is a non-conductor of electricity. Melts at a little over 100°, at a higher temperature NH_3 is given off, along with H and N, and K_3N remains (*v.* POTASSIUM NITRIDE, p. 304). Burns when heated in O, or heated to redness in air, giving N and KOH; decomposes in moist air to KOH and NH_3; must, therefore, be kept under rock oil. Reacts energetically with water, giving NH_3 and KOHAq.

Potassium-ammonium or Potassammonium. By evolving dry NH_3, from $AgCl.xNH_3$, in a Faraday tube containing K in the other end, Weyl (*P.* 121, 697) obtained a substance which he regarded as an alloy, or compound, of K and NH_4. Seeley (*C. N.* 23, 169) regarded the blue liquid formed by dissolving K in liquid NH_3 as a solution, inasmuch as K was obtained again when the NH_3 was allowed to evaporate. Joannis (*C. R.* 109, 900, 965; 110, 238) examined the vapour-pressures of a solution of K in liquid NH_3, and also the thermal phenomena attending the formation of the solution. He found the vapour-pressure to decrease till a certain value was reached, when it became constant, provided temperature was not changed; on removal of more NH_3 a copper-red solid separated, and thereafter NH_3 was given off at constant pressure, till only K remained. This last part of the process was regarded by J. as a dissociation of NH_3K; analysis showed this ratio (NH_3:K) to be always attained when the final part of the change commenced. The heat of formation of NH_3K is given by J. as 6,300 when NH_3 is gas and K solid, and as 1,900 when NH_3 is liquid and K solid. Joannis (*C. R.* 113, 795) found that NH_3K in liquid NH_3 is decomposed by Sb, Pb, and Hg, but not by Al, Cu, Ag, or Zn; by dropping the liquid on to Hg, and washing the product with liquid NH_3, he obtained a crystalline amalgam $Hg_{18}K$.

By measuring the depression of the vapour-pressure of liquid NH_3 by solution of K therein, J. concludes that the mol. formula of potassammonium is $N_2H_6K_2$ (*C. R.* 115, 820).

Potassium, antimonide of. Probably SbK_3. A greyish-white, lustrous solid; decomposes water, giving KOH, Sb, and H. Formed by heating the elements together, or by fusing Sb_2O_3 with K_2CO_3 and C.

Potassium, antimonates of; *v.* vol. i. p. 286.

Potassium, arsenates of; *v.* vol. i. p. 309.

Potassium, arsenites of; *v.* vol. i. p. 306.

Potassium, auricyanide of; *v.* vol. ii. p. 332.

Potassium, borates of; *v.* vol. i. p. 529.

Potassium, boride of. The brown solid formed when boric acid is reduced by heating K may contain a compound of B and K.

Potassium, borofluoride of; *v.* vol. i. p. 526.

Potassium, boronitride of. By very strongly heating a mixture of 7 parts B_2O_3 with 20 parts KCN, Balmain (*J. pr.* 27, 422) obtained a white, infusible solid; insol. water or KOHAq; decomposed by boiling *aqua regia*, leaving BN (vol. i. p. 527); heated in steam gave off NH_3, and left KOH and boric acid.

Potassium, bromide of, KBr. Formula probably molecular, from analogy of KI. Melts at 699° (Carnelley, *C. J.* 33, 279). S.G. 2·695 to 2·72 at 4° (Schröder, *P.* 106, 226); 2·712 at 12·7° (Clarke's *Tables of Spec. Gravities*, 2nd ed., 31); 2·199 *fused* (Quincke, *P.* 138, 141): *v.* also Spring (*B.* 16, 2724). S.H. (16° to 98°) ·11322 (Regnault, *A. Ch.* [3] 1, 129). Vol. at 40° = vol. at 0° (1 + ·00012602) (Fizeau, *C. R.* 64, 314). S. 53·48 at 0°, 64·6 at 20°, 74·62 at 40°, 84·74 at 60°, 93·46 at 80°, 102·04 at 100° (Kremers, *P.* 25, 119); Coppet (*A. Ch.* [5] 30, 411) gives S. 54·43 + ·5128*t* where *t* varies from −13·4° to 110°. Gerlach (*Fr.* 8, 285) calculated the following from Kremer's data:

S.G. KBrAq

5 p.c.	1·037	30 p.c.	1·256
10 „	1·075	35 „	1·309
15 „	1·116	40 „	1·366
20 „	1·159	45 „	1·430
25 „	1·207		

H.F. [K,Br] = 95,310; [K,Br,Aq] = 90,230 (*Th.* 3, 235). [KBr,O³] = 84,060 (*Th., l.c.*).

Formation.—1. K and Br combine with production of much heat (*v.* Balard, Merz, a. Weith, *B.* 6, 1518).—2. By treating BrAq with iron filings and ppg. with K_2CO_3.—3. By neutralising HBrAq by KOHAq or K_2CO_3Aq, and evaporating.—4. By decomposing $CaBr_2$Aq by K_2SO_4, filtering after 12 hours, adding K_2CO_3 as long as turbidity is produced, filtering, and evaporating (Klein, *A.* 128, 237).

Preparation.—A moderately conc. solution of KOH, free from K_2CO_3, is prepared from pure K_2CO_3 and pure CaO (*v.* Potassium hydroxide, p. 302); to this solution Br is added, little by little, till the liquid is slightly yellow; very finely-powdered charcoal, equal to about one-tenth of the quantity of Br used, is added, and the liquid is evaporated to dryness ($6KOHAq + 3Br_2 = 5KBrAq + KBrO_3Aq + 3H_2O$); the dry residue is well powdered, and heated to dull redness in a closed crucible for some time ($2KBrO_3 + 3C = 2KBr + 3CO_2$); the residue is extracted with warm water, the solution is filtered, and evaporated to the crystallising point.

Properties and Reactions.—KBr crystallises in very lustrous, white cubes, sometimes elongated to prisms or flattened to plates; it has a strongly saline taste. Easily sol. water, with considerable lowering of temperature; [KBr,Aq] = −5,080 (*Th.* 3, 235). *Chlorine* reacts with KBrAq to give KClAq and Br; Br is not set free by H_2SO_4 containing N_2O_3, nor by KNO_2Aq + dil. H_2SO_4Aq. KBr heated with *potassium chromate and sulphuric acid* gives off Br; KCl under similar conditions gives CrO_2Cl_2. *Conc. sulphuric acid* produces HBr, Br, and SO_2; the amount of HBr (the primary product of the reaction) thus decomposed varies very nearly in proportion to the quantity of H_2SO_4 used; if the H_2SO_4 is in such large excess that the water formed in the reaction causes no sensible dilution, only SO_2 and Br are produced; by using dil. H_2SO_4Aq (c. 30 p.c.) a mere trace of Br is obtained, the products being almost wholly $KHSO_4Aq$ and HBrAq (*v.* Addyman, *C. J.* 61, 94). *Hypochlorous acid* solution produces KClAq and $KBrO_3Aq$, with evolution of Br and Cl. *Potassium permanganate* solution has no action even when boiled; but Br is set free if a little H_2SO_4 is added, even without warming, the decomposition being soon completed (Hempel, *A.* 107, 160). Fusion with *potassium chlorate* produces $KBrO_3$.

Combinations.—With many *bromides of less positive metals* to form double salts; some of these are best regarded as K salts of acids containing Br and a metal less positive than K, *e.g.* $AuBr_3.KBr$ is best looked on as $KAuBr_4$ (*v.* the various metallic bromides). Also with *iodine bromide*, to form KBr.IBr (Wells a. Wheeler, *Am. S.* [3] 43, 475). Also with some *metallic chlorides*; thus $SbCl_3$ forms $SbCl_3.3KBr$ identical with $SbBr_3.3KCl$, and therefore to be regarded as $SbK_3Cl_3Br_3$ (Atkinson, *C. J.* 43, 290). Feit (*J. pr.* [2] 39, 378) describes $MgBr_2.KBr.6aq$, analogous to *carnallite* ($MgCl_2.KCl.6aq$). Schiff (*A.* 228, 72) describes a compound with *arsenious oxide* $KBr.As_4O_6$.

Potassium tribromide KBr_3. According to Berthelot (*A. Ch.* [5] 21, 370), orange crystals of this composition are formed by adding Br to KBrAq; no analyses are given. The substance decomposes rapidly. B. gives [KBr,Br²] = 2940.

Potassium, carbonyl compound of. (*Carbonic oxide potassium.*) The black solid formed in the preparation of K was thought by Berzelius (*P.* 4, 31) to be a carbide; Liebig (*A.* 11, 182) found that the same compound was formed by passing CO over K heated just to melting; Brodie (*C. J.* 12, 269) confirmed Liebig's result, and determined that one molecule CO is absorbed for each atom K; hence the empirical formula is probably KCO. This substance is extremely explosive; many serious accidents have occurred with it. If the CO used is quite dry, and the substance is washed rapidly in alcohol as soon as it is prepared, the residue is not nearly so explosive (Nietzki a. Benckiser, *B.* 18, 1833, where details of the method of preparation are given); probably the alcohol dissolves out unchanged K. *Potassium carbonyl* is a greyish solid; on standing in air it becomes yellowish and very explosive; it dissolves in water, with evolution of much gas (according to E. Davy [*A.* 23, 144] this gas contains C_2H_2), and generally with combustion or explosion; heated to redness it is resolved into K and CO. By exposure to moist air, or by other processes of oxidation, a series of organic compounds is obtained (*v.* Croconic acid, vol. ii. p. 275; Hexa-oxy-benzene, vol. iii. p. 678; Tetra-oxy-quinone, vol. iii. p. 771; Rhodizonic acid, this vol.).

Potassium, chloride of, KCl. Formula probably molecular, from analogy of KI. Melts at 734° (Carnelley, *C. J.* 33, 279). S.G. 1·9775 at 4° (Playfair a. Joule, *C. S. Mem.* 2, 401); 1·9453 at 15° (Stolba, *J. pr.* 97, 503); 1·612 at M.P. (Braun, *C. J.* [2] 13, 31); 1·87 *fused* (Quincke, *P.* 135, 642); *v.* also Spring (*B.* 16, 2721). S.H. 14° to 99° ·17295 (Regnault, *A. Ch.* [3] 1, 129; *v.* also Kopp, *T.* 155 [1] 71). Vol. at 40° = vol. at 0° (1 + ·00011408) (Fizeau, *C. R.* 64, 314). S. 32 at 10°, 33·4 at 15°, 34·7 at 20°, 37·4 at 30°, 40·1 at 40°, 42·8 at 50°, 45·5 at 60°, 48·3 at 70°, 51 at 80°, 53·8 at 90°, 56·6 at 100° (Mulder, *Scheikund. Verh.* 1864. 39); Coppet (*A. Ch.* [5] 30, 411) gives S. 28·51 + ·2837t°, where t° varies from −11° to 109°. S. at 0° in alcohol is given in following table (Gerardin, *A. Ch.* [4] 5, 139); where S.G. of alcohol is at 0°, and S + t° is solubility at t° (*cf.* Schiff, *A.* 126, 167):

Alcohol S.G.	S.	t°	Alcohol S.G.	S.	t°
·9904	23·2	·27	·9573	7·1	·162
·9848	19·4	·255	·9390	4·2	·125
·9793	15·7	·233	·8767	1·89	·061
·9726	11·9	·205			

Gerlach (*Fr.* 8, 281) gives the following data:

S.G. KClAq

1	per	cent.	1·0065	20	per	cent.	1·1861
5	„	„	1·0325	24	„	„	1·1657
10	„	„	1·0658	24·9	„	„	1·1723
15	„	„	1·1004				

H.F. [K,Cl] = 105,610; [K,Cl,Aq] 101,170 (*Th.* 3, 285). 30 parts KCl dissolved in 100 parts water at 13·2° lower the temperature to ·6°, *i.e.* through 12·6° (Rüdorff, *B.* 2, 68). Solution of 1 g. KCl in 100 g. water freezes at −·446°; saturated solution freezes at −10·9° (Rüdorff, *P.* 114, 63; 122, 337). Saturated solution boils at 108°.

Occurrence.—In small quantities in sea-water, and in some mineral springs. As chloride in *sylvine*; as double chloride, especially as *carnallite* KCl.$MgCl_2$.6aq. In crude pearl ash, in plant ash, and in kelp.

Formation.—1. By the direct union of the elements; K burns in Cl at the ordinary temperature.—2. By heating K in HCl gas.—3. By passing Cl over KOH or KI heated to redness.—4. By the action of HClAq on KOH or K_2CO_3.—5. By decomposing various metallic chlorides by fusion with K.

Preparation.—1. Commercial KCl is prepared chiefly from *carnallite*. The mineral is dissolved in warm water, heated by steam to c. 120°, and allowed to cool; at 60°–70°, $MgSO_4$.aq, $CaSO_4$, and NaCl separate, and on further cooling c. 70 p.c. of the KCl is obtained; the crystals of KCl are washed with a little cold water, to remove NaCl and $MgCl_2$, and a product containing c. 95 p.c. KCl is thus obtained (for details *v.* Dictionary of Applied Chemistry).—2. Pure KCl is prepared by neutralising pure HClAq by pure KOH or K_2CO_3, evaporating to the crystallising point, and recrystallising from water.

Properties.—White salt, crystallising in cubes. Saline taste. Unchanged in air. Decrepitates when heated; melts at c. 740°, and volatilises at a higher temperature. Fairly sol. water or aqueous alcohol; insol. absolute alcohol, or conc. HClAq; sol. in 20 p.c. $KC_2H_3O_2$Aq.

Reactions.—1. With *acids*, KCl generally gives K salt of the acid used and HCl.—2. Said to combine with *sulphuric anhydride*, and *chromic anhydride*, probably forming SO_2.Cl.OK and CrO_2.Cl.OK respectively (H. Rose, *P.* 38, 117).—3. Fused with *potassium*, in H, a blue substance is formed, supposed by H. Rose to be a subchloride (*P.* 120, 15). What is probably the same substance is formed during *electrolysis* of molten KCl (Bunsen a. Kirchoff, *P.* 113, 344). 4. For action of *water and oxygen*, in presence and absence of acids, *v.* Schulze, *J. pr.* [2] 21, 407.

Combinations. — 1. With *sulphuric* and *chromic anhydrides*, *v. Reactions*, No. 2.—2. With most *metallic chlorides*; some of the compounds are best regarded as K salts of metal-containing acids, *e.g.* $KAuCl_4$ (*v.* the different *metallic chlorides*). — 3. With *iodine trichloride*, to form KCl.ICl_3; prepared by mixing KClAq and ICl_3Aq, by passing Cl into warm KIAq containing HCl, or by dissolving 1 part KIO_3 in 8 parts HClAq of S.G. 1·176, at 40°–50°. Forms lustrous yellow prisms, smelling of Cl; on heating gives Cl, KCl, and ICl; with water forms KIO_3; ether dissolves out ICl_3 (Filhol, *J. Ph.* 25, 435, 506).—4. With *iodine monochloride*, to form KCl.ICl (Wells a. Wheeler, *Am. S.* [3] 43, 475).

Potassium, cyanide of; *v.* vol. ii. p. 346.

Potassium, chromicyanide of; chromisulphocyanide of; and chromocyanide of; *v.* vol. ii. p. 330.

Potassium, cobalti- and cobalto-cyanide of; *v.* vol. ii. p. 330.

Potassium, ferrate and ferrite of; *v.* vol. ii. p. 547.

Potassium, ferri- and ferro-cyanide of; *v.* vol. ii. pp. 339, 336.

Potassium, fluorides of. Two fluorides are known, KF, and KHF_2 or KF.HF.

Potassium fluoride KF. Formula probably molecular, from analogy of KI. Prepared by neutralising HFAq by K_2CO_3 in a dish of Ag or Pt, evaporating to dryness, and heating till HF ceases to be given off. According to Berzelius (*P.* 2, 218), KF is obtained in crystals by slowly evaporating an aqueous solution at 35°–40° in a very shallow dish. Deliquescent; fusible; solution has alkaline reaction to litmus, and etches glass. Guntz (*A. Ch.* [6] 3, 5) says KFAq is neutral, but the salt is decomposed in solution and becomes alkaline. Evaporation of a very conc. solution gives KF.$2H_2O$, according to H. Rose. S.G. 2·454 (Bödeker); 2·096 at 21·5° (Clarke, *Am. S.* [3] 13, 291). Combines with HF to form KF.HF (*v. infra*); with BF_3 to form KBF_4 (*v.* Potassium borofluoride, vol. i. p. 526); with SiF_4 to form K_2SiF_6 (*v.* p. 305); with B_2O_3 to form 2KF.B_2O_3, obtained by dissolving B_2O_3 in molten KF (Schiff, *A.* 228, 72); with TeF_4 to form KF.TeF_4, by evaporating TeO_3 in HFAq with addition of K_2CO_3 (Högborn, *Bl.* [2] 35, 60); and with many metallic fluorides.

Potassium-hydrogen fluoride KHF_2 or KF.HF. Prepared by dividing a quantity of HFAq into two equal parts, neutralising one, adding the other, and evaporating; also by evaporating KF in acetic acid. White cubes or four-sided tables; e. sol. water, almost insol. dil. HFAq. When heated gives HF, leaving KF. By electrolysis of HF containing KHF_2, F is obtained (*v.* Fluorine, vol. ii. p. 561). Moissan (*C. R.* 106, 547) says that two other compounds of KF and HF are obtained by dissolving dry KF in liquid HF, and cooling; to these compounds he gives the formulæ KF.2HF and KF.3HF. Guntz (*A. Ch.* [6] 3, 5) gives [HF,KF] = 21,100.

Potassium, haloid compounds of. The compounds KF, KCl, KBr, and KI are the chief halides of K; as KI has been gasified and the molecular weight corresponds with the simplest formula, it is probable that KX expresses the molecular composition of these halides. KI_3 also exists, but is decomposed by heat; and there are indications of the existence of KBr_3. KF combines with HF to form KHF_2, and, according to Moissan, also KF.2HF and KF.3HF.

Potassium, hydride of, K_2H. The absorption of H by heated K was observed by Gay-Lussac a. Thénard (*A. Ch.* 74, 203), and was confirmed by Jacquelain. Troost a. Hautefeuille (*A. Ch.* [5] 2, 273) found that the absorption of H by K begins at c. 200° and becomes rapid at 350°–400°; if the action continues for some time 126 vols. H are absorbed by 1 vol. K. The product is brittle, and much resembles Ag amalgam; it is fusible without change in H or *in vacuo*; takes fire in contact with air; heated *in vacuo*, dissociation begins at 200° (for vapour-pressures of H given off, *v.* Dissociation, vol. ii. p. 398). The formula K_2H requires 124·6 vols H to 1 vol. K.

Potassium, hydrosulphide of, KHS (*Potassium sulphydrate*). Gay-Lussac a. Thénard (*A. Ch.* 115, 165) obtained this compound by heating K in dry H_2S gas; it is more readily formed by heating K_2CO_3 to redness in H_2S (H_2O and CO_2 are given off) (Berzelius, *P.* 6, 438). By saturating KOHAq with H_2S, and evaporating the conc. solution over CaO or $CaCl_2$ *in vacuo*, Schöne (*P.* 131, 380) obtained lustrous, rhombohedral crystals of $2KHS.H_2O$; and by dehydrating this in a stream of dry H_2S, Sabatier (*A. Ch.* [5] 22, 5) obtained KHS as a yellow, amorphous solid. Prepared in the dry way, KHS appears reddish-black when molten, and white when cold; it crystallises in prisms; is very deliquescent, and reacts strongly alkaline; easily sol. in alcohol. Thomsen (*Th.* 3, 235) gives [K,S,H,Aq] = 65,140. KHSAq gives off H_2S at 70°, according to Drechsel (*J. pr.* [2] 4, 20). When a current of an inert gas is passed through KHSAq, H_2S is given off, and K_2SAq remains (Gernez, *C. R.* 64, 606). Electrolysis produces H and KOH at the negative pole, and H_2S at the positive (Bunge, *B.* 3, 911). KHSAq dissolves S with evolution of H_2S; it ppts. MnS, or PbS, from a neutral solution of a Mn or Pb salt, at the same time giving off H_2S. These reactions distinguish KHSAq from K_2SAq; the latter does not give off H_2S while dissolving S or ppg. MnS or PbS. KHSAq dissolves several sulphides of the less positive metals, *e.g.* Sb, As, Sn, forming K thiosalts.

Potassium, hydroxide of, KOH (*Caustic potash. Potassium*, or *potassic, hydrate*). S.G. 2·1 (Dalton); 2·044 (Filhol, *A. Ch.* [3] 21, 415). H.F. [K,O,H] = 103,170; [K,O,H,Aq] = 116,460 (*Th.* 3, 235).

Formation.—1. By the reaction between K and H_2O, or K_2O and H_2O, followed by evaporation.—2. By boiling K_2CO_3Aq with CaO.—3. By adding powdered K_2SO_4 to warm conc. BaOAq, evaporating, filtering, and again evaporating (Schubert, *J. pr.* 26, 117).—4. By heating KNO_3 with 2-3 parts thin copper turnings, to redness, in an iron, or copper, crucible, extracting with water when cold, filtering from CuO and Cu_2O, and evaporating (Wöhler, *A.* 87, 373).—5. By heating 1 part KNO_3 with 1 part Fe_2O_3, in a closed crucible of Cu, H being passed in; treating with water, and drawing off the clear liquid, and evaporating it (Schulze, *Z.* 1861. 109). Evaporation of KOHAq should be performed in vessels of polished iron, or, better, of silver.

Preparation.—1. A solution of pure K_2CO_3 in 10-12 parts water is boiled, in a dish of silver or polished iron, with milk of lime, added little by little, till a portion of the clear supernatant liquid gives no effervescence with an acid; rather more than half as much CaO is required as the weight of K_2CO_3 taken; large excess of CaO should be avoided; water should be added as the boiling proceeds, because if the quantity of water is less than c. 10 times the quantity of K_2CO_3 used the KOHAq begins to decompose the $CaCO_3$ formed, and the change of K_2CO_3 to KOH stops (Liebig, *A.* 1, 124). When the change is completed, the vessel is closed, and, after a few hours, the clear liquid is drawn off by a syphon; the liquid is then rapidly evaporated in an iron vessel, allowed to stand for an hour or two, the vessel being closed, syphoned off from any pp. that has formed, evaporated in a silver dish till the oily liquid thus produced begins to volatilise in white clouds, and cooled in an exsiccator. Impure KOH may be freed from all impurities, except KCl and traces of K_2CO_3 and $KC_2H_3O_2$, by dissolving in absolute alcohol, allowing to settle, draining off, and evaporating, at first on a water-bath, in a silver dish; the resinous matter which is produced is removed from the warm evaporated semi-solid mass, by a silver spatula, and the KOH is then poured out on to a plate of polished iron, or, better, of silver.

Graeger (*J. pr.* 96, 188) recommends to heat the K_2CO_3Aq used with Ag_2CO_3, to filter from AgCl and excess of Ag_2CO_3, to boil, in a silver dish, with pure CaO made by strongly heating pure $CaCO_3$, to filter the solution of KOH through pounded marble which has been washed with water till free from very fine particles, and to evaporate in a silver dish.—2. Water and benzene are placed in a silver dish, and small pieces of K, cut from the inside of a lump, are thrown in one by one; the K remains near the surface of separation of the two liquids, and reacts fairly slowly with the water. The benzene is removed by warming, and the aqueous solution of KOH is then evaporated to dryness.

Properties.—After fusion, KOH is a white, hard, brittle solid, often showing a fibrous texture. Melts below red heat, and volatilises at full redness in white pungent vapour. Very deliquescent; sol. water with production of much heat, [KOH,Aq] = 13,290 (*Th.* 3, 235). Easily sol. alcohol. Skey (*C. N.* 36, 48) says KOH is very sl. sol. ether. Absorbs CO_2 rapidly from the air, forming $KHCO_3$. KOH has a slight, but nauseous, odour, a strongly acrid taste, and acts as a powerful cautery towards both animal and vegetable matter. KOHAq should be kept in glass vessels free from Pb, as it corrodes lead-glass; it attacks vessels of glass or porcelain when heated in them. To keep KOHAq free from carbonate, it is advisable to store it in bottles fitted with corks carrying a syphon-tube, and a rather wide tube filled with a mixture c. equal parts CaO and Na_2SO_4, well rubbed together, dried over a flame, and passed through a sieve to remove fine powder; the air which enters through this mixture is quite free from CO_2.

KOHAq is strongly alkaline; the affinity of KOH in solution is large, about equal to that of NaOH and LiOH, and about 50 times greater than NH_3Aq (Ostwald). KOH saponifies ethereal salts, and ppts. most of the heavier metals as oxides or hydroxides from solutions of their salts.

The table on next page, given by Lunge, shows the composition of KOHAq of different S.G.

Expansion occurs when conc. KOHAq is diluted; Frankenheim (*J.* 1847-8. 69) gives $V = 1 + \cdot000415t + \cdot000000577t^2$ as representing the volume of KOHAq S.G. 1·2738 at 0°, between 13° and 100°.

Reactions.—1. According to Deville (*C. R.* 45, 857), KOH is decomposed to K, O, and H by *heating to white heat.*—2. Strongly heated with *non-volatile acidic anhydrides*, water and potass[illegible] salts are formed.—3. Heated with *potassium*, K_2O and H are formed; heated with *sodium* under a liquid free from O, an alloy of K and Na

is said to be formed (Williams, *Rép. Chim. pure*, 3, 177).—4. *Iron* decomposes KOH at white heat, forming Fe_2O_3, H, and K.—5. *Molten KOH acts generally as an oxidiser : e.g.* Fe, As, Sb, Pt, &c. form ferrate, arsenate, antimonate, and platinate of K; Cr_2O_3 forms K_2CrO_4, &c. Salts are generally decomposed by molten KOH, giving K salts, and setting free the bases.—6. KOHAq neutralises *acids*, forming salts.—7. KOHAq decomposes most *metallic salts in solution*, ppg. oxides or hydroxides of the metals.—8. According to Schöne (*A.* 193, 241), addition of *hydrogen peroxide* to KOHAq produces K_2O_4 (*v.* POTASSIUM TETROXIDE, p. 305).

Combinations.—1. With *carbon dioxide*, to form $KHCO_3$.—2. With *water*, to form hydrates. Pickering (*C. J.* 63, 890) obtained $KOH.H_2O$ freezing at 143°, $KOH.2H_2O$ freezing at 35·5°, and $KOH.4H_2O$ freezing −32·7° (*cf.* Walter, *P.* 39, 192; Schöne, *P.* 131, 147). P. (*l.c.*) gives full data for freezing points of KOHAq. Göttig (*B.* 20, 1094) described two hydrates, $2KOH.9H_2O$ and $2KOH.5H_2O$, obtained from an alcoholic solution of KOH containing some water; but in a later paper (*B.* 20, 1907) G. says that these hydrates contained alcohol besides water. 3. With *methyl alcohol*, to form 3KOH.5MeOH (Göttig, *B.* 20, 1832). 4. With *ethylic alcohol*, to form KOH.2EtOH (Engel, *C. R.* 103, 155); decomposed by heating to EtOK, EtOH, and H_2O.

Potassium, iodides of. Two iodides are known, KI and KI_3.

POTASSIUM IODIDE, KI. Mol. w. 165·57. Melts at 634° (Carnelley, *C. J.* 33, 279). S.G. 3·059 (Playfair a. Joule, *C. S. Mem.* 2, 401); 3·077 to 3·081 (Schröder, *P.* 106, 226); *fused* 2·497 (Quincke, *P.* 138, 141); *v.* also Spring (*B.* 16, 2724). V.D. 91·5 (Dewar a. Scott, *Pr.* 29, 206); 84·6 at above 1300°, in N (Mensching a. Meyer, *Z. P. C.* 1, 157). S.H. (20° to 99°) ·08191 (Regnault, *A. Ch.* [3] 1, 129). Vol. at 40° = vol. at 0° (1 + ·00012796) (Fizeau, *C. R.* 64, 314). S. 132·1 at 5°, 136·1 at 10°, 140·2 at 15°, 144·2 at 20°, 152·3 at 30°, 160 at 40°, 168 at 50°, 176 at 60°, 184 at 70°, 192 at 80°, 201 at 90°, 209 at 100°, 218 at 110° (Mulder, *Scheikund. Verhandel*, Rotterdam, 1864. 162). Coppet (*A. Ch.* [5] 30, 411) gives S. at $t° = 126·23 + ·8088t$, where t varies from −5·9° to 120°. S. in aqueous alcohol is given in following table (Gerardin, *A. Ch.* [4] 5, 139); the values hold for 0° to 18°:

S.G. alcohol	S.	S.G. alcohol	S.
·9904	130·5	·9528	76·9
·9851	119·4	·9390	66·4
·9726	100·1	·9088	48·2
·9665	89·9	·8464	11·4
		·8322	6·2

H.F. [K,I] = 80,130; [K,I,Aq] = 75,020 (*Th.* 3, 235).

Formation.—1. By the direct union of K and I.—2. By neutralising HIAq by K_2CO_3, and evaporating.—3. I is added to water and iron filings till the iron is almost wholly dissolved, the solution is filtered, and K_2CO_3 added so long as $FeCO_3$ ppts.; the liquid is filtered (if alkaline it is neutralised by HIAq) and evaporated, any Fe_2O_3 which separates being filtered off (Baup, *J. Ph.* 9, 37, 122).—4. By adding I to KOHAq, evaporating, heating with C, dissolving, filtering, and evaporating (*v. Preparation*).—5. BaI_2Aq is formed by the action of I and water on BaS, and is decomposed by K_2SO_4; $BaSO_4$ is filtered off, and the liquid is evaporated. Liebig (*A.* 121, 222) used CaI_2 in place of BaI_2 (*cf.* Pettenkofer, *A.* 121, 225).

Preparation.—Moderately, but not too, conc. KOHAq, quite free from K_2CO_3, is prepared from K_2CO_3Aq and CaO (*v.* Potassium hydroxide, *Preparation*, p. 302); I is added, little by little, to the slightly warm liquid till a slight yellow colour is produced; very finely powdered charcoal is now added, equal to c. $\frac{1}{10}$ of the weight of I used, the liquid is evaporated quite to dryness, the residue is powdered, and heated, in a closed crucible, to dull redness for some time ($6KOHAq + 6I = 5KIAq + KIO_3Aq + 3H_2O$; $KIO_3 + 3C = KI + 3CO$). The contents of the crucible, when cold, are extracted with water, the liquid is filtered, neutralised by HIAq if alkaline, and crystallised. Morse a. Burton (*Am.* 10, 321) recommend to remove traces of KIO_3 by boiling for some time with Zn amalgam and water, filtering, and crystallising; neither Zn nor Hg is found in the filtrate. The Zn amalgam is made by agitating zinc-dust with Hg in presence of tartaric acid solution, and washing with water.

Properties.—White cubes; non-deliquescent. Has a sharp taste. Solution in water is attended with fall of temperature; 140 pts. in 100 pts. water at 10·8° produce a fall to −11·7° (Rüdorff, *P.* 136, 276).

Reactions.—1. Unchanged in dry air, but decomposed in *ordinary air when exposed to sunlight* (*v.* Downes a. Blunt, *Pr.* 29, 319; Loew, *Fr.* 1870. 251). Air containing ozone also decomposes KI (Houzeau, *J.* 1858. 60).—2. *Heated in air* to 230°, some KIO_3 is formed.—3. *Heated in steam*, I is evolved (Petterson, *Fr.* 1870. 362) and HIAq formed (Schindler, *Mag. Pharm.* 31, 33).—4. Decomposed, with separation of I, and formation of KOH, by heating with *lead dioxide, manganese dioxide, arsenic oxide, antimonic oxide, chromium trioxide, hydrogen peroxide*, &c. (*v.* Weltzien, *A.* 138, 134).—5. *Chlorine* decomposes hot KI to KCl and I. KIAq with ClAq gives KClAq, and I; with excess of Cl, ICl_3 is formed and remains in solution, or combines with the KCl and separates as $KCl.ICl_3$, according to the quantity of water present. *Bromine* acts similarly to Cl.—6. *Nitrous acid solution* sets I free; KNO_2 and dil. HClAq act in the same way (*v.* Price, *C. J.* 4, 155).—7. *Conc. sulphuric acid*, or *nitric acid*, decomposes KI when heated with it, giving sulphate or nitrate of K, and I; with H_2SO_4, SO_2 and H_2S are also formed. Addition of conc. H_2SO_4 to KIAq, or evaporation with HNO_3Aq, sets I free. If KIAq contains KIO_3 a few drops of a dilute acid suffice to give free I ($5HIAq + HIO_3Aq = 3I_2 + 3H_2O$). *Aqua regia* sets I free from KIAq (for the delicacy of this reaction *v.* Harting, *J. pr.* 22, 46).—8. Heated with *sulphuric anhydride*, K_2SO_4, SO_2, and I are formed (H. Rose, 38, 121).—9. *Manganese dioxide and sulphuric acid* produce I, $MnSO_4$, and K_2SO_4 when heated with KI.—10. KI fused with *potassium-hydrogen sulphate* gives K_2SO_4 and I.—11. Fusion with *potassium chlorate* produces KIO_3.—12. Heating with *barium nitrate* forms KIO_3 and BaO_2 (Henry, *J. Ph.* 18, 345).—13. By heating with *ammonium chloride*, I, AmI, and KCl are formed.—14. *Conc. potassium ferricyanide solution* gives I and K_4FeCy_6Aq; on dilution the action is reversed (Mohr, *A.* 105, 57).—15. Heated with *potassium borate*, KIO_3 and a polyborate (? probably $K_2B_8O_{13}$) are formed (Schiff, *A.* 228, 72).

Combinations.—1. With most *iodides of less positive metals* (*v.* various *metallic iodides*). Several of the compounds produced are best regarded as K salts of metal-containing acids (*v.* Remsen, *Am.* 11, No. 5).—2. With *arsenious oxide* to form $KI.As_4O_6$ (Schiff, *A.* 228, 72).—3. With *potassium ferricyanide*, to form a very unstable compound, $KI.K_3FeCy_6$ (Preuss, *A.* 29, 323; Mohr, *A.* 105, 57; Blomstrand, *J. pr.* [2] 3, 207; Kern, *C. N.* 33, 184).

Potassium tri-iodide KI_3. Dark-blue, lustrous needles; almost black by reflected light; melts at 45°; S.G. 3·498 at c. 15°; by saturating KIAq with I, and evaporating over H_2SO_4 (Johnson, *C. J.* 31, 249). Very deliquescent; in a little water some I is deposited; sol. alcohol, in a very small quantity water, and in saturated solution of I in KIAq. Agitation with CS_2 of conc. KIAq saturated with I abstracts the dissolved I (Baudrimont, *C. R.* 51, 827). Jörgensen (*J. pr.* [2] 2, 347) found, however, that CS_2 did not remove the I from an alcoholic solution of KI containing excess of I in ratio KI:2I, and that alcoholic KI completely decolourised solutions of I in CS_2.

Potassium di-iodide ?KI_2. A solution of 3 pts. I in 4 pts. KI in water is said by Guyard (*Bl.* [2] 31, 297) to contain an unstable compound of this composition; with $Pb(NO_3)_2Aq$ or $Pb(C_2H_3O_2)_2Aq$, this solution gives an almost black pp., said by G. to be PbI_4.

Potassium, iodobromide of. The compound KBr.IBr may be called iodobromide of potassium; *v.* Potassium bromide, *Combinations*, p. 300.

Potassium, iodochlorides of. The compounds $KCl.ICl_3$ and KCl.ICl may be called iodochlorides of potassium; *v.* Potassium chloride, *Combinations* Nos. 3 and 4, p. 301.

Potassium, iridicyanide of; *v.* vol. ii. p. 332.

Potassium mangani- and mangano-cyanide of; *v.* vol. ii. p. 342.

Potassium, nitride of, K_3N. Formed by heating to redness KNH_2 (*v.* Potassium amide, p. 299) in absence of O. A dark-grey, almost black, solid. Sublimes partially at white heat. Takes fire in air, with evolution of N; reacts with water to give KOHAq and NH_3. K_3N is a conductor of electricity. Combines with S and P (Gay-Lussac a. Thénard, *A. Ch.* 65, 325).

Potassium, nitroprusside of; *v.* vol. ii. p. 341.

Potassium, osmocyanide of; *v.* vol. ii. p. 343.

Potassium, oxides of. Two oxides have been certainly isolated, K_2O and K_2O_4; there are indications of the existence of others.

Potassium oxide K_2O (*Potassium monoxide*). A mixture of K_2O and K_2O_4 is formed by burning K in air; when K is burnt in a stream of dry O only K_2O_4 is produced, but on strongly heating this product O is given off, and K_2O remains (Davy, *T.* 1808 [1] 5). K_2O is also formed by heating KOH and K in the ratio KOH : K; according to Beketoff (*Bl.* [2] 37, 491), K and KOH do not react. B. says that K_2O may be prepared by heating a mixture of K_2O_4 and K in a silver dish. To prepare pure K_2O Kühnemann (*C. C.* 1864. 491) recommends to lead air, freed from CO_2, over K heated just to fusion; the K spreads out into a thin layer which burns to K_2O. K_2O is a greyish, non-lustrous solid; S.G. 2·656 (Karsten, *S.* 65, 394); melts at full red-heat, and volatilises at a very high temperature. Thomsen (*Th.* 3, 235) gives $[K^2,O,Aq] = 165,460$. K_2O reacts with water to form KOHAq, with production of much heat. Von Schaffgotsch (*A.* 43, 17) says that $K_2O.Fe_2O_3$ is obtained, but not pure, by heating Fe_2O_3 with K_2CO_3.

POTASSIUM TETROXIDE K_2O_4 (*Potassium peroxide*). The formation of this compound by heating K in dry air or O was observed by Gay-Lussac a. Thénard (*A. Ch.* 65, 325). The preparation and properties of the compound were examined by Vernon Harcourt (*C. J.* 14, 267). Prepared by heating K till it melts, in a hard glass flask filled with N, then sending in a slow stream of dry air, and continuing to heat in the air-stream until the metal is completely changed to a yellowish amorphous solid, and heating this for some time in dry O. It is also formed by throwing small pieces of K into molten KNO_3 (Bolton, *C. N.* 52, 289). A mixture of K_2O_4 with $KOH.H_2O$ is said to be formed by mixing equivalents of KOH and H_2O_2 in Aq, and evaporating *in vacuo* (Schöne, *A.* 193, 241). K_2O_4 is an amorphous powder, having the colour of $PbCrO_4$. It begins to soften at 280°, and melts at red heat to a black liquid, which crystallises in leaflets on cooling. At white heat gives off O and leaves K_2O. Deliquesces in moist air, giving off O. In water forms KOHAq and H_2O_2Aq, and evolves O. Heated in H produces KOH and H_2O. K_2O_4 oxidises P, S, C, &c., and many metals to their highest oxides. Reacts with CO, when heated, giving K_2CO_3 and O. No action with N_2O; with NO forms KNO_2 and KNO_3, and gives off N oxides.

OXIDES OF POTASSIUM OTHER THAN K_2O AND K_2O_4. Harcourt (*l.c.*) asserted the existence of K_2O_2, obtained by oxidation of K. Lupton (*C. J.* 1876. [2] 565) thought that the oxides K_8O_5, K_4O_3, and K_6O_4 are formed by the action of air on K at c. 65°; these oxides may be regarded, according to L., as $3K_2O.K_2O_2$, $K_2O.K_2O_2$, and $2K_2O.K_2O_2$ respectively. The substance described as a sub-oxide, K_4O, is said by L. to be a mixture of K and K_2O. Schöne (*A.* 193, 241) obtained $K_2H_4O_6$, probably $K_2O_2.2H_2O_2$, by evaporating, *in vacuo*, at −10°, a mixture of 1 equiv. KOH and 2 equivs. H_2O_2 in Aq.

Potassium, phosphide of. K and P combine when heated under rock-oil, or in N, forming a dark-yellow solid (Magnus, *P.* 17, 517; Vigier, *A.* 122, 331). A compound, or compounds, of K and P seems also to be formed when K is heated in PH_3, and also when K is heated in P in a stream of H (H. Rose, *P.* 12, 547). The compound prepared by Rose was a crystalline, reddish, lustrous solid; decomposed by water, giving KH_2PO_2Aq and PH_3, and burning, when heated in air, to K phosphate.

Potassium, platinocyanide of, *and allied salts*; *v.* vol. ii. pp. 344–5.

Potassium, salts of. *Compounds formed by replacing H of acids by K.* The chief salts of K, besides the halides and sulphides, are *carbonates, chlorate and perchlorate, chromate and derivatives, iodate and periodates, nitrate and nitrite, phosphates and derivatives, silicates, sulphates and derivatives, sulphite, thiosulphate* (*v.* CARBONATES, PHOSPHATES, &c.).

Potassium, selenides of. Berzelius (*Lehrbuch*, 5th ed. 2, 222) investigated the conditions of combination of K and Se, without isolating and analysing any definite compounds. Se and K combine when melted together; a steel-grey solid sublimes, which dissolves in water with formation of a red liquid that decomposes in air with separation of Se, and gives off H_2Se with acids. Compounds of Se and K are also formed by reducing K_2SeO_4 or K_2SeO_3 by C or H at red heat (Wöhler a. Dean, *A.* 97, 5; Rathke, *A.* 152, 211). Mixtures of selenate and selenides of K are formed by fusing KOH or K_2CO_3 with Se. Boiling KOHAq dissolves Se, forming a brown liquid, from which a brown powder separates on evaporation, and which gives Se when heated with acids, or when diluted and allowed to stand in air.

Fabre (*C. R.* 102, 613) obtained $K_2Se.xH_2O$, $x = 9$, 14, and 19, by passing a rapid current of H_2Se into KOHAq of different concentrations; these *hydrates of potassium monoselenide* are all very easily decomposed. Fabre (*C. R.* 102, 703) gives the following thermal data: $[K^2,Se] = 98,340$ from solid elements; $[2KOHAq,H_2SeAq] = 7,520$; $[2KOHAq,H_2Se] = 16,920$; $[K^2Se,Aq] = 8,540$.

Potassium, selenocyanide of, *v.* vol. ii. p. 348.

Potassium, selenostannate of, K_2SnSe_3 3aq. Yellow, unstable crystals; by saturating K_2SeAq with $SnSe_2$ and evaporating *in vacuo* (Ditte, *C. R.* 95, 641).

Potassium, selenothiostannate of, K_2SnSe_2S 3aq. Yellow, octahedral crystals; by boiling K_2SAq with Sn and Se, and evaporating *in vacuo*. Sol. water, with red colour. Both solid and solution in water very readily undergo decomposition, with separation of Se (Ditte, *l.c.*).

Potassium, silicide of. By reducing SiO_2 by K, Berzelius obtained a brown solid, which reacted with water to give H, KOHAq, and SiO_2 (*Lehrbuch*, 5th ed. 2, 84).

Potassium, silicofluoride of, K_2SiF_6. Prepared by adding H_2SiF_6Aq to a fairly conc. solution of a K salt, washing, and drying. Small tesseral white crystals. Preis (*Listy Chem.* 13, 150; abstract in *C. J.* 58, 694) found hexagonal, and also regular, crystals of this salt, along with $CaSO_4$, in a basin wherein phosphoric acid had been prepared from *phosphorite*. K_2SiF_6 is isodimorphous with the ammonium salt. S.G. 2·665 at 17·5° (Stolba, *J. pr.* 97, 503). Easily sol. hot water, very sl. sol. cold water. Melts at low red heat, giving off SiF_4 and leaving KF (*v.* Bothe, *Hofman's Ber. über die Entwick. der Chem. Industrie*, 1, 318). Decomposed by conc. H_2SO_4, giving off SiF_4 and HF. Decomposed by boiling (not cold) solutions of alkali hydroxides or carbonates, with separation of gelatinous silicic acid and formation of KF.

Potassium, siliconitride of. The white, infusible solid, obtained by heating SiO_2 with KCN, is probably a compound of K, Si, and N (Balmain, *P. M.* October 1842).

Potassium, sulphides of. K and S combine when heated together, the K burning brilliantly. Five compounds of K and S are known: K_2S, K_2S_2, K_2S_3, K_2S_4, and K_2S_5. They are all sol. water, the polysulphides also in alcohol. K_2SAq is colourless; solutions of the others are coloured yellowish brown, the colour being deeper the greater the proportion of S. Solutions are decomposed by acids; K_2SAq with evolution of H_2S, the other solutions also with ppn. of S. Solutions decompose in air; K_2SAq to $K_2S_2O_3Aq$ and KOHAq, K_2S_2Aq to $K_2S_2O_3Aq$, and the others to $K_2S_2O_3Aq$ with separation of S. Solutions of the polysulphides react with K_2SO_3Aq to form K_2SAq and $K_2S_2O_3Aq$; these solutions are reduced to K_2SAq by shaking with Hg. With EtI or EtBr they form Et_2S_2, which dissolves the S set free; these solutions dialyse unchanged (Spring a. Demarteau, *Bl.* [3] 1, 311).

Potassium monosulphide K_2S. Formed by reducing dry K_2SO_4; by heating in H (Berzelius, *P.* 6, 438); by heating with C (Berthier, *A. Ch.* 22, 233; Bauer, *J. pr.* 75, 246; Wittstock, *P.* 55, 536). Not obtained free from polysulphides by these methods; if vessels of glass or porcelain are used the product contains SiO_2, as K_2S acts on silicates. The product of the foregoing reactions is a brown, crystalline, deliquescent solid; sol. in water, with production of much heat and formation of KSHAq and KOHAq; Thomsen (*Th.* 3, 235) gives $[K^2,S,Aq] = 113{,}300$. Sabatier (*A. Ch.* [5] 22, 5) says that K_2S has never been obtained pure. An aqueous solution of K_2S is prepared by saturating KOHAq with H_2S, and adding an equal quantity of the same KOHAq. By evaporating this solution *in vacuo* at a low temperature, the *pentahydrate* $K_2S.5H_2O$ is obtained in orthorhombic crystals, which lose $3H_2O$ by heating to 150°, out of air (Schöne, *P.* 131, 380; *cf.* Sabatier, *l.c.*). K_2SAq is colourless out of contact with air; it is very alkaline and caustic; in air it becomes yellow, H_2S is given off, and K_2CO_3Aq and $K_2S_2O_3Aq$ are formed. K_2SAq dissolves S, forming polysulphides; it dissolves Fe or Fe_2O_3, forming a green liquid.

Potassium disulphide K_2S_2. Formed by allowing an alcoholic solution of K_2S to stand in air till the surface is covered with a film of $K_2S_2O_2$, then pouring off, and evaporating *in vacuo* (Berzelius, *l.c.*). Also by heating 2 equivalents $KHSO_4$ with 7 or more equivalents C (Geiger). Berzelius obtained K_2S_2 by heating 4 equivalents K_2CO_3 with rather less than 7 equivalents S. A yellowish red, deliquescent solid; K_2S_2Aq is yellow; in air it oxidises to $K_2S_2O_3Aq$ without separation of S; acids give off H_2S and cause ppn. of S.

Potassium trisulphide K_2S_3. Formed by passing CS_2 over K_2CO_3 heated to redness (Berzelius, *l.c.*; *cf.* Schöne, *l.c.*). Also by heating 100 parts K_2CO_3 with 58·22 parts S to dull redness, till CO_2 ceases to be given off; the product contains some K_2SO_4. Also, with some S, by passing H_2S over strongly-heated K_2SO_4. By heating K_2S_4 to over 800°. A yellowish-brown solid, black when molten; not decomposed at 900°, gives off S at white heat (B.). Easily sol. water and alcohol; K_2S_3Aq in air gives $K_2S_2O_3Aq$ with separation of S; decomposed by acids, S separating and H_2S being evolved.

Potassium tetrasulphide K_2S_4. Formed by passing CS_2 over strongly-heated K_2SO_4 so long as CO_2 is produced. Also by melting K_2CO_3 with 1 to 2 parts S, heating till excess of S is removed, and then reducing K_2SO_4 formed by heating in H_2S. A red-brown, crystalline solid (B., *l.c.*; S., *l.c.*). Decomposed at 800°–900° to K_2S_3 and S. The *dihydrate* $K_2S_4.2H_2O$ is obtained by boiling K_2SAq with the proper quantity of S, and evaporating *in vacuo* (S., *l.c.*). Sabatier (*A. Ch.* [5] 22, 53) obtained the *octahydrate*, $K_2S_4.8H_2O$, by adding 90 p.c. alcohol to K_2S_4Aq, separating the brown oily liquid, and letting it crystallise.

Potassium pentasulphide K_2S_5. Formed by heating any of the lower sulphides with S until the excess is removed; Schöne (*l.c.*) says temperature should not exceed 600° (*v.* B., *l.c.*). A solution of K_2S_5, containing also $K_2S_2O_3$, is formed by heating K_2CO_3Aq with S (Fordos a. Gélis, *C. R.* 23, 211); or by digesting a solution of a lower sulphide with S (B., *l.c.*). A red, fusible solid; decomposed by heating in steam, giving K_2SO_4 and H_2S (Drechsel, *J. pr.* [2] 4, 20). Very sol. water, also in alcohol; K_2S_5Aq slowly decomposes in air, giving $K_2S_2O_3Aq$, K_2CO_3Aq, and S; acids evolve H_2S and separate S.

Liver of sulphur. This name is given to the brown solid obtained by heating S with K_2CO_3 in a closed vessel; it contains various sulphides of K, along with K_2SO_4, and generally some K_2CO_3.

Potassium, sulphydrate of; *v.* Potassium hydrosulphide, p. 302.

Potassium, sulphocyanide of; *v.* vol. ii. pp. 351–2.

Potassium, telluride of. Probably K_2Te. By heating together K and Te in H; also by heating a mixture of 100 pts. H_2TeO_3, 20 pts. KOH, and 10 pts. C. A brittle, crystalline, copper-coloured solid. Easily sol. water; exposed to air Te separates from the solution. HClAq evolves H_2Te (Davy; *v.* also Berzelius, *Lehrbuch* (5th ed.) 2, 247).

Potassium, tellurofluoride of, $KF.TeF_4$; *v.* Potassium fluoride, p. 301.

Potassium, thio-arsenates and thio-arsenites of; *v.* vol. i. pp. 317, 316.

Potassium, thiocarbonate of; *v.* vol. i. p. 703.

M. M. P. M.

PRASEODYMIUM. The constituent of didymium which yields green-coloured salts; *v.* Didymium, vol. ii. p. 383.

PREHNITENE *v.* *c*-Durene.

PREHNITIC ACID $C_{10}H_6O_8$ *i.e.* $C_6H_2(CO_2H)_4$[1:2:3:4]. Mol. w. 254. [237°–250°]. Formed by heating either of the tetrahydrides of pyromellitic acid with H_2SO_4 (Baeyer, *A.* 166, 325), and by the oxidation of *c*-durene and of *c*-tetra-ethyl-benzene (Töhl, *B.* 21, 907; Galle, *B.* 16, 1746; Jacobsen, *B.* 17, 2518). Crystallises from water in large prisms (containing 2aq) resembling the mineral prehnite. Converted by fusion into an anhydride $C_{10}H_4O_7$ [239°]. May be reduced to a viscid hydride.—KH_3A^{iv}aq.—$BaH_6A^{iv}_2$ 3aq.—BaH_2A^{iv} aq: needles.—Pb_2A^{iv}: small needles, insol. water.

Methyl ether Me_4A^{iv}. [104°–108°].

PREHNITOL *v.* *c*-Durenol.

PREHNOMALIC ACID $C_{10}H_8O_9$ *i.e.* $C_6H_3(OH)(CO_2H)_4$. *Oxy-prehnitic acid dihydride.* [210°]. A product of the action of H_2SO_4 on the tetrahydrides of mellitic acid (Baeyer, *A.* 166, 325; *B.* 4, 275). Needles, readily converted by heat into an anhydride $C_{20}H_{14}O_{17}$ [210°]. By heating with H_2SO_4, or by treatment with Br, it is converted into prehnitic acid.—Ag_4A^{iv}.

PRIMULA CAMPHOR $C_{11}H_{12}O_5$. [49°]. (above 200°). Contained in the root of *Primula* *veris* (Mutschler, *A.* 185, 222). Six-sided plates, v. sl. sol. water, v. sol. alcohol and ether. Smells like anise. $FeCl_3$ colours its aqueous solution violet. Yields salicylic acid on oxidation.

PRIMULINE BASE $C_{28}H_{18}N_4S_3$ *i.e.*
$C_6H_3Me<^{N}_{S}>C.C_6H_3<^{N}_{S}>C.C_6H_3<^{N}_{S}>C.C_6H_4.NH_2$.
Prepared by heating *p*-toluidine (2 mols.) with sulphur (4 or 5 atoms), H_2S being evolved (Green, *C. J.* 55, 234). Yellowish powder, nearly insol. all solvents. Not decomposed at 400°. Its salts are decomposed by water. The Na salt of its sulphonic acid (primuline), is taken up by unmordanted cotton. KOH at 260° yields amido-tolyl-mercaptan and *p*-amido-benzoic acid (Gattermann, *B.* 22, 425, 1066).

Dehydrothiotoluidine $C_{14}H_{12}SN_2$ *i.e.* $C_6H_3Me<^{N}_{S}>C.C_6H_4.NH_2$. [191°]. (434° at 766 mm.) (Pfitzinger a. Gattermann, *B.* 22, 1066). An intermediate body in the preparation of primuline. Formed, together with primuline base, by heating *p*-toluidine with S (Dahl & Co., *G. P.* 35790; Green, *C. J.* 55, 230). Got also by the action of HI and P upon primuline (Jacobsen, *B.* 22, 330). Yellowish iridescent needles (from isoamyl alcohol), v. sol. HOAc, sl. sol. hot alcohol, v. sl. sol. benzene, almost insol. boiling water. Its alcoholic solutions have violet-blue fluorescence. Ppd. by adding water to its solution in HClAq.

Reactions.—1. Yields *p*-toluidine on distillation with zinc-dust.—2. Yields primuline on heating with S.—3. Converted by diazotisation in boiling alcoholic solution into $C_6H_3Me<^{N}_{S}>CPh$ [123°].—4. When diazotised and boiled with water it gives $C_{14}H_{11}(OH)N_2S$ [256°], which gives $C_{14}H_{11}(OAc)N_2S$ [132°].—5. Fuming H_2SO_4 (containing 70 p.c. SO_3) forms, below 50°, a sulphonic acid $C_{14}H_{11}(SO_3H)SN_2$, which crystallises in yellow needles (containing aq), or orange plates (containing 2aq), sl. sol. hot water, and forms $NH_4A'aq$, sl. sol. hot water, $CuA'_2 2aq$, a reddish-brown pp., and AgA', a white pp.—6. MeI yields $C_{14}H_{10}(NMe_2)NS$ [197°] (434°), and $C_{14}H_{10}(NMe_3I)NS$, a bright-yellow powder, v. sol. water. MeOH and HCl at 150°–200° give $C_{14}H_{10}(NMe_3Cl)NS$, a yellow powder which forms $(C_{14}H_{10}NS.NMe_3Cl)_2PtCl_4$ [234°].

Acetyl derivative $C_{14}H_{11}AcN_2S$. [227°]. White plates or prisms, sl. sol. HOAc.

PROPACONIC ACID *v.* *Lactone* of Oxy-butylmaleïc acid.

PROPANE C_3H_8 *i.e.* $CH_3.CH_2.CH_3$. Mol. w. 44. (−·17°). S. (alcohol) 6. H.F.p. 35,110. H.F.v. 33,370 (Thomsen, *Th.* 4, 52). Occurs in the gases given off from the petroleum springs of the United States (Ronalds, *C. J.* 18, 54; Lefevre, *Z.* [2] 5, 185). Formed by the action of HI on propyl iodide, allyl iodide, isopropyl iodide, acetone, and glycerin (Berthelot, *Bl.* 7, 60; 9, 13, 184). Prepared by heating *n*-propyl iodide (9·6 pts.) with $AlCl_3$ (2·5 pts.) at 140° (Köhnlein, *B.* 16, 560), or by heating isopropyl iodide with zinc and HClAq (Schorlemmer, *A.* 150, 209). Gas. On compression with water at a low temperature it yields a hydrate, dissociating at 8·5° (Villard, *C. R.* 111, 302).

References.—Di-bromo-, Bromo-iodo-, Bromo-nitro-, Chloro-, Chloro-iodo-, Di-chloro-nitro-, Di-iodo, and Nitro- Propane.

PROPANE CARBOXYLIC ACID *v.* Butyric acid.

Propane dicarboxylic acid *v.* Glutaric, Pyrotartaric, and Ethyl-malonic acids.

Propane tricarboxylic acid $C_6H_8O_6$ *i.e.* $CH_3.CH(CO_2H).CH(CO_2H)_2$ (Bischoff, *B.* 13, 2164; 14, 614; 15, 1107; 17, 2783; 22, 3180; *A.* 214, 53). [146°]. Formed by saponifying the ether with dilute alcoholic potash. Crystalline mass, v. e. sol. water, alcohol, and ether. Splits up when heated alone, or with dilute HClAq, into CO_2 and pyrotartaric acid. Bromine forms bromopyrotartaric and bromocrotonic acids.—$Ba_3A'''_2$: bulky pp.

Methyl-di-ethyl ether $MeEt_2A'''$. (268°). S.G. ${}^{15}_{4}$ 1·078. Formed from methyl α-chloro-propionate and sodium malonic ether.

Ethyl ether Et_3A'''. (270·3° cor.). S.G. ${}^{20}_{4}$ 1·0698. $\mu_D = 1·4288$ at 20°. Formed from sodium malonic ether and α-bromo-propionic ether. Oil, miscible with alcohol and ether. NaOEt yields $C_3H_4Na(CO_2Na)(CO_2Et)_2$.

Propane tricarboxylic acid $CH_3.C(CO_2H)_2.CH_2.CO_2H$.

Methyl ether Me_3A'''. Oil (Barthe).

Ethyl ether Et_3A'''. (273·5° cor.). S.G. ${}^{15}_{4}$ 1·077. $\mu_D = 1·4311$ at 20°. Formed from sodium methyl-malonic ether and chloro-acetic ether, and also from sodium ethane tricarboxylic ether and MeI or MeCl (Bischoff a. Von Kuhlberg, *B.* 23, 635). Yields on saponification pyrotartaric and a little succinic acid.

Methyl ether of the mono-nitrile $CH_3.C(CN)(CO_2Me).CH_2.CO_2Me$. Formed from methyl cyanosuccinate, MeOH, and MeI at 70° (Barthe, *Bl.* [3] 1, 303; *C. R.* 108, 297; 112, 1013). Oil. The corresponding $CH_3.C(CN)(CO_2Et).CH_2.CO_2Et$ is also an oil (185° at 35 mm.).

Propane tricarboxylic acid $CO_2H.CH_2.CH_2.CH(CO_2H)_2$.

Ethyl ether Et_3A'''. (161° at 13 mm.). S.G. ${}^{20}_{4}$ 1·0808. Formed from sodium malonic ether and β-bromo-propionic ether (Emery, *B.* 24, 282). The free acid splits up into CO_2 and glutaric acid on boiling with HClAq.

Isomeride *v.* Tricarballylic acid.

Propane tetracarboxylic acid $CO_2H.CH_2.CH(CO_2H).CH(CO_2H)_2$.

Ethyl ether Et_4A^{iv} (204° at 18 mm.). S.G. ${}^{20}_{4}$ 1·1184. Formed from sodium malonic ether and chloro-succinic ether (Emery, *B.* 23, 3759). Oil, v. sol. alcohol and ether. The free acid splits up into CO_2 and tricarballylic acid.

Propane tetracarboxylic acid $(CO_2H)_2CH.CH_2.CH(CO_2H)_2$. *Dicarboxy-glutaric acid.* [170°]. An acid formed by the action of sodium amalgam on dicarboxyglutaconic ether $C_7H_2Et_4O_8$ in alkaline solution (Conrad a. Guthzeit, *A.* 222, 257). One of the products of the action of chloro-di-methyl oxide on sodium malonic ether (Kleber, *A.* 246, 106). Got also by boiling its ether with dilute alcoholic potash (Guthzeit a. Dressel, *B.* 21, 2234; 22, 1423; *A.* 256, 174). Crystalline powder (from ether), v. e. sol. water. At 180° it splits up into CO_2 and glutaric acid [98°].—Ba_2A^{iv} 2aq.—Ca_2A^{iv} 2aq.—Pb_2A^{iv} 2aq.

Ethyl ether Et_4A^{iv}. (235° at 30 mm.).

S.G. $\frac{12}{12}$ 1·116. Formed from sodium malonic ether by treatment with CH_2Cl_2 or CH_2I_2, and got also by reducing dicarboxy-glutaconic ether with zinc-dust and HOAc (W. H. Perkin, jun., *C. J.* 59, 993). Oil, with very bitter taste. NaOEt forms a di-sodium derivative, which reacts with EtI forming oily $C_{17}H_{28}O_8$ (c. 248° *in vacuo*).

Propyl-tri-ethyl ether Et_3PrA^{iv}. (195°–202° at 15 mm.). Formed from propyl triethyl dicarboxy-glutaconate, zinc-dust, and HOAc. Colourless oil.

Propane tetracarboxylic acid $CO_2H.CH_2.C(CO_2H)_2.CH_2.CO_2H$. [151°]. Got by saponifying its ether with alcoholic potash. Prisms (from water), v. sol. water, alcohol, and ether. At 170° it splits up into CO_2 and tricarballylic acid.—K_3HA^{iv} 2½aq (at 100°).—Zn_2A^{iv} 3aq (dried at 100°).—Pb_2A^{iv} aq.—Ag_4A^{iv}: insoluble pp.

Ethyl ether Et_4A^{iv}. (295° uncor.). S.G. $\frac{15}{15}$ 1·102. Formed from malonic ether, alcoholic NaOEt, and chloro-acetic ether, followed by a second dose of NaOEt and chloro-acetic ether (Bischoff, *B.* 13, 2163; *A.* 214, 61). Oil.

Ethyl ether of the mono-nitrile $CO_2Et.CH_2.C(CN)(CO_2Et).CH_2.CO_2Et$. [41°]. (200°–215° at 10 mm.). Formed from sodium cyano-succinic ether and chloro-acetic ether (Haller a. Barthe, *C. R.* 106, 1413). White crystals, sol. alcohol and ether.

Methyl ether of the mono-nitrile $CO_2Me.CH_2.C(CN)(CO_2Me).CH_2.CO_2Me$. [47°]. Prepared in like manner (Barthe, *C. R.* 111, 844). Prisms, insol. water and alkalis.

Propane pentacarboxylic acid $CH(CO_2H)_2.C(CO_2H)_2.CH_2.CO_2H$. [151°]. Got by saponifying its ether. Spherical aggregates (from ether).—K_5A^{v} 4aq.—$Ba_5A^{v}_2$ 4aq: crystalline pp.

Ethyl ether Et_5A^{v}. (275°–280° at 188 mm.). S.G. $\frac{15}{15}$ 1·121 (Bischoff, *B.* 15, 1107; 21, 2113). Formed from sodium-malonic ether and $CCl(CO_2Et)_2.CH_2.CO_2Et$. Formed also from sodium ethane tricarboxylic ether and chloro-acetic ether. Oil.

Reference.—OXYPROPANE TRICARBOXYLIC ACID.

PROPANE PHOSPHONIC ACID $C_3H_7.PO(OH)_2$. [60°–70°]. Prepared by oxidation of propyl-phosphine with fuming HNO_3 (Hofmann, *B.* 6, 304). Wax-like mass, sol. water.

PROPANE SULPHONIC ACID $CH_3.CH_2.CH_2.SO_3H$. Formed by oxidation of propyl mercaptan with nitric acid (S.G. 1·3) (Spring a. Winssinger, *Bl.* [2] 48, 110). ICl_3 at 160° forms chloro-propane sulphonic acid, CCl_4, and C_2Cl_6.

Propane sulphonic acid $(CH_3)_2.CH.SO_3H$. [below 100°]. Formed by oxidising isopropyl mercaptan with HNO_3. Obtained also from acetone by successive treatment with P_2S_5 and HNO_3 (Claus, *B.* 5, 660; 8, 533; Spring, *Bl.* [2] 40, 66). Crystalline. Its salts are v. e. sol. water.

Propane disulphonic acid $CH_2(SO_3H).CH_2.CH_2(SO_3H)$. Formed by boiling trimethylene bromide with a saturated solution of ammonium sulphite (Monari, *B.* 18, 1345). Deliquescent needles, v. sol. water and alcohol.—Na_2A'' 4½aq.—BaA'' 2aq: very soluble needles.

Propane disulphonic acid $CH_3.CH(SO_3H).CH_2(SO_3H)$. Formed in like manner from propylene bromide (M.).—Na_2A''aq.—BaA'': sparingly soluble crystals.

Propane disulphonic acid $C_3H_6(SO_3H)_2$. Got from butyramide and fuming H_2SO_4 (Buckton a. Hofmann, *A.* 100, 153), and also by heating butyric acid with $ClSO_3H$ at 140° (Baumstark, *A.* 140, 83).—BaA''.—PbA'': crystalline.

Propane trisulphonic acid $CH_2(SO_3H).CH(SO_3H).CH_2(SO_3H)$. Got by boiling *s*-tri-chloro-propane with aqueous K_2SO_3 (Schäuffelin, *A.* 148, 117).—$Ba_3A'''_2$: crystalline powder, sl. sol. water.

References.—CHLORO- and OXY-PROPANE SULPHONIC ACID.

DIPROPARGYL C_6H_6 *i.e.* $CH{\vdots}C.CH_2.CH_2.C{\vdots}CH$. *Hexunene.* (85°). S.G. $\frac{18}{}$ ·81. H.F.p. −96,040. H.F.v. −97,200 (Thomsen, *Th.*). Formed by distilling diallyl tetrabromide with solid KOH, and boiling the resulting di-bromo-diallyl with alcoholic potash (Henry, *B.* 6, 956; 7, 21; 14, 399; 17, 1132). Limpid, highly refractive oil, v. sol. ether. Burns with smoky flame. Combines with explosive violence with bromine, forming $C_6H_6Br_4$, a thick liquid S.G. $\frac{12}{}$ 2·464, from which, by further action of Br, crystalline $C_6H_6Br_8$ [141°] can be obtained. Iodine in KI forms dipropargyl tetraiodide $C_6H_6I_4$ [113°] crystallising from CS_2 in prisms. Dipropargyl gives with ammoniacal cuprous chloride a yellow pp. $Cu_2C_6H_4$ 2aq, which explodes at about 100°. Aqueous $AgNO_3$ ppts. $Ag_2C_6H_4$ 2aq, which explodes below 100°. Dipropargyl is very easily polymerised, forming a resin.

PROPARGYL ALCOHOL C_3H_4O *i.e.* $CH{\vdots}C.CH_2OH$. Mol. w. 56. (115°). V.D. 1·88 (calc. 1·93). S.G. $\frac{20}{4}$ ·9715. $\mu_\beta = 1·437$. $R_\infty = 24·01$ (Brühl). H.F.p. −3,500. H.F.v. −4,370 (Thomsen, *Th.*). Formed by boiling bromo-allyl alcohol with KOHAq (Henry, *B.* 5, 274, 449, 569; 6, 728; 7, 20, 761). Formed also from propargylamine oxalate, $NaNO_2$, and HCl (Paal a. Hempel, *B.* 24, 3039). Colourless liquid of peculiar odour, sol. water.

Reactions.—1. Ammoniacal Cu_2Cl_2 ppts. canary-yellow $Cu_2(C_3H_3O)_2$ which explodes when heated, and is decomposed by dilute acids with reproduction of propargyl alcohol.—2. Ammoniacal $AgNO_3$ ppts. white AgC_3H_3O.—3. Anhydrous BaO forms $Ba(C_3H_3O)_2C_3H_4O$, crystallising in small plates.—4. On heating with solid KOH it yields formic acid and acetylene.—5. HBr forms bromo-allyl alcohol.—6. HNO_3 yields CO_2 and oxalic acid.

Acetyl derivative $C_3H_3.OAc$. (125°). S.G. $\frac{20}{4}$ 1·0052. $\mu_\beta = 1·427$. $R_\infty = 39·71$ (Brühl). Got from the alcohol and AcCl.

Methyl ether C_3H_3OMe. (62°). S.G. $\frac{12·5}{}$ ·83. H.F.p. −10,910. H.F.v. −12,360 (Thomsen, *Th.*). Formed by boiling *s*-tri-bromo-propane with KOH dissolved in MeOH (Liebermann, *A.* 135, 287) and by boiling the dibromide of methyl allyl oxide with alcoholic potash (Henry). Ammoniacal $AgNO_3$ ppts. lemon-yellow $C_3H_2Ag.OMe$, whence I in KI forms oily $C_3H_2I.OMe$ [12°].

Ethyl ether C_3H_3OEt. (81°–85°). S.G. $\frac{20}{4}$ ·8326. $\mu_\beta = 1·4096$. $R_\infty = 39·5$ (Brühl). This body is formed by the action of alcoholic potash on $CH_2Br.CHBr.CH_2Br$, on $CH_3.CBr_2.CH_2Br$,

on dichloropropylene, or on ethyl bromo-allyl oxide (Liebermann, *A.* 135, 278; 158, 230; Henry, *B.* 5, 274; Baeyer, *A.* 138, 196). Mobile liquid, with penetrating odour, v. sl. sol. water, miscible with alcohol. Combines with Br, forming $C_3H_3Br_2.OEt$. Boiling very dilute (1 p.c.) H_2SO_4 splits it up into alcohol and propargyl alcohol. Sodium forms C_3H_2NaOEt. Alcoholic silver nitrate forms crystalline $(C_3H_2Ag.OEt)_2AgNO_3$ converted by ammonia into amorphous C_3H_2AgOEt, whence I in KI forms crystalline C_3H_2IOEt and oily $C_3H_2I_3OEt$. An ammoniacal solution of AgCl added to an alcoholic solution of C_3H_3OEt ppts. white $(C_3H_2AgOEt)_2AgCl$. Ammoniacal Cu_2Cl_2 gives yellow amorphous C_3H_2CuOEt.

Isoamyl ether $C_3H_3OC_5H_{11}$. (140°-145°).

PROPARGYLAMINE $C_3H_3NH_2$. Formed by the action of NaOEt on bromo-allyl-amine and on di-bromo-propyl-amine (Paal a. Hermann, *B.* 22, 3080). The free base has not been isolated. —$B'H_2C_2O_4$. [143°]. Large tables (from water), sl. sol. alcohol. Gives a white pp. with ammoniacal $AgNO_3$.—$B'C_6H_2(NO_2)_3OH$. [189°]. Large red plates or tables.—B'HCl.—B'HBr. [130°-171°].—B'HI. [205°]. White plates, v. e. sol. water.

PROPARGYL-ISOAMYL-AMINE $C_8H_{15}N$ *i.e.* $C_3H_3.NHC_5H_{11}$. Formed from di-bromo-isoamyl-amine and NaOEt (Paal a. Hermann, *B.* 22, 3084). Liquid.—$B'H_2C_2O_4$ aq. [204°]. White needles (from water).—B'HBr. [186°]. Pearly plates.

PROPARGYL BROMIDE $CH:C.CH_2Br$. (89°). S.G. ^{11} 1·59. Formed from propargyl alcohol and PBr_3 (Henry, *B.* 6, 728). Liquid.

Propargyl tribromide *v.* Tri-bromo-propylene.

PROPARGYL-ISOBUTYL-AMINE $C_7H_{13}N$ *i.e.* $CH:C.CH_2.NH.CH_2Pr$. (135°). Formed from di-bromo-propyl-isobutyl-amine and NaOEt (Paal a. Heupel, *B.* 24, 3045). Liquid, miscible with water.—B'HCl. [148°].—$B'_2H_2PtCl_6$. [172°].—$B'H_2C_2O_4$. [210°]. Needles and plates, m. sol. cold water.

PROPARGYL CHLORIDE C_3H_3Cl. (65°). S.G. ^{5} 1·045. Formed from propargyl alcohol and PCl_3 (Henry, *B.* 8, 398). Mobile oil.

PROPARGYLIC ACID is Propiolic acid.

PROPARGYL IODIDE $CH:C.CH_2I$. (c. 115°). S.G. ^{0} 2·018. Formed from propargyl bromide and NaI in alcohol (Henry, *B.* 17, 1132). Yellowish liquid. Iodine forms $CHI:CI.CH_2I$. [41°].

PROPARGYL-PROPYL-AMINE $C_6H_{11}N$ *i.e.* $C_3H_3.NH.C_3H_7$. The salt B'HBr [180°] is got from propyl bromide and propargylamine (Paal a. Hermann, *B.* 22, 3084).

PROPARGYL SULPHOCYANIDE C_3H_3SCN. Formed from propargyl bromide and potassium sulphocyanide (Henry, *B.* 6, 729). Oil, smelling like mustard. Decomposed by heat.

PROPARGYL-DI-THIO-CARBAMIC ACID $CH:C.CH_2.NH.CS_2H$. [115°]. Formed by boiling propargylamine with CS_2 and alcohol (Paal a. Heupel, *B.* 24, 3041). Needles (from dilute alcohol) or plates (from benzene-ligroïn).

PROPENYL-*o*-AMIDO-PHENOL CARBOXYLIC ETHER $C_6H_4<^{O}_{NH}>CMe.CH_2.CO_2Et$. **[108°]. Formed by heating a mixture of *o*-amidophenol and acetoacetic ether (Hantzsch, *B.* 16, 1948). Flat prisms, readily resolved into the parent substances by dilute acids, alkalis, or even boiling water.**

PROPENYL-*o*-AMIDO-PHENYL MERCAPTAN C_9H_9NS *i.e.* $C_6H_4<^{N}_{S}>CEt$. (252°). Formed by heating *o*-amido-phenyl mercaptan with propionyl chloride at 160° (Hofmann, *B.* 13, 21). Heavy oil.—$B'_2H_2PtCl_6$: large prisms.

PROPENYLAMINE $CH_3.CH:CH.NH_2$. Formed by the action of baryta on *β*-bromo-propylamine (Hirsch, *B.* 23, 968). Does not decolourise bromine water.—$B'_3H_3I_3 2BiI_3$: six-sided plates.

PROPENYL-BENZENE SULPHONIC ACID $CH_2:CMe.C_6H_4.SO_3H$. The salts of this acid are formed by heating the dry salts of the acid $CMe_2(OH).C_6H_4.SO_3H$ (R. Meyer, *A.* 219, 302).

Amide $C_9H_9SO_2NH_2$. [152°].

***o*-PROPENYL-BENZOIC ACID** $CH_2:CMe.C_6H_4.CO_2H$. [61°]. Formed from di-methyl-phthalide and KCy at 260° (Wislicenus, *A.* 248, 64). Needles (from water).

***p*-Propenyl-benzoic acid** $CH_2.CMe.C_6H_4.CO_2H$. [161°]. Formed by heating $(CH_3)_2.C(OH).C_6H_4.CO_2H$ with dilute HCl on a water bath (R. Meyer a. J. Rosicki, *B.* 11, 1791; *A.* 219, 270). White satiny plates (from 1 pt. alcohol and 1 pt. water) or slender needles (from water). Sl. sol. hot water, v. e. sol. alcohol and ether. Sodium amalgam reduces it to cuminic acid.

Salts.—NH_4A'.—BaA'_2 aq.—CuA'_2 7aq.—AgA': amorphous pp.

Methyl ether.—MeA' [53°]. (254° cor.). V.D. 6·09. Insol. water.

Isopropenyl-benzoic acid $C_3H_5.C_6H_4.CO_2H$ [255°-260°]. By boiling oxy-propyl-benzoic acid $(CH_3)_2C(OH).C_6H_4.CO_2H$ with fuming HCl (R. Meyer, *B.* 12, 1076; *A.* 219, 281). Minute needles grouped in stars (from alcohol). Insol. water. Does not decolourise bromine, and is not reduced by sodium amalgam, but is converted by HI into cuminic acid. Hence it would appear to be a polymeride of propenyl-benzoic acid, not containing a C:C group.

Salts.—NH_4A'aq. Sl. sol. water.—BaA'_2aq.—$CaA'_2 1\frac{1}{2}$aq.—CuA'_2.—AgA': pp., insol. water.

Methyl ether MeA'. [83°]. Decomposed by heat.

References.—Amido-, Nitro-, and Oxy- Propenyl-benzoic acid.

PROPENYL BROMIDE *v.* Bromo-propylene.

PROPENYL CARBINOL *v.* Butenyl alcohol.

PROPENYL-TRICARBOXYLIC ACID *v.* Propanetricarboxylic acid.

PROPENYL CHLORIDE *v.* Chloro-propylene.

PROPENYL-PHENOL. *Methyl derivative v.* Anethol.

PROPENYL-ISOPROPYL BENZENE $C_{12}H_{16}$ *i.e.* $Pr.C_6H_4.CH:CHMe$. (230°). S.G. ^{15} ·890. Got by boiling $Pr.C_6H_4.CH_2.CBrMe.CO_2H$ with Na_2CO_3Aq (Perkin, *C. J.* 1877, ii. 660). *Dibromide* $C_{12}H_{16}Br_2$ [59°].

PROPENYL-SALICYLIC ACID *v.* Oxy-propenyl-benzoic acid.

PROPEPTONE *v.* Proteïds.

PROPHETIN $C_{22}H_{36}O_7$. **A bitter resin got from the fruit of *Cucumis prophetarum*, split up**

by boiling dilute HClAq into glucose and prophetein $C_{20}H_{30}O_4$ (Walz, *J.* 1859, 566).

PROPINENE *v.* ALLYLENE.

PROPINENE DIPHTHALIDE $C_{19}H_{12}O_4$ *i.e.* $C_6H_4\!<\!\begin{smallmatrix}\text{—C:CMe.CH:C—}\\ \text{CO.O}\qquad\quad\text{O.CO}\end{smallmatrix}\!>\!C_6H_4$. Formed by heating phthalic anhydride (3 pts.) with pyrotartaric acid (3 pts.) and sodium acetate (1 pt.) at 240°–290° (Roser, *B.* 17, 2776). Fine yellow needles, not melted at 280°.

PROPIO-GUANAMINE $C_5H_9N_5$ *i.e.*  $\begin{matrix}CH_2Me.C{:}N.C(NH)\\ NH.C(NH)\end{matrix}\!>\!NH$. Got by heating guanidine propionate at 230° for an hour (Haaf, *J. pr.* [2] 43, 78). Granules (from NaOHAq) or dimetric prisms (from water).

PROPIO-HOMO-FERULIC ACID *v.* DI-OXY-PHENYL-CROTONIC ACID.

PROPIOLIC ACID $C_3H_2O_2$ *i.e.* $CH{:}C.CO_2H$. *Propargylic acid.* [6°]. (c. 144°). Formed by boiling the acid K salt of acetylene dicarboxylic acid with water (Bandrowski, *B.* 13, 2340). Liquid, solidifying at about 4°. Smells like acetic acid. Turns brown in air. Sol. water, alcohol, and ether. Reduces $HgCl_2$, $AgNO_3$, and $PtCl_4$.
